Alexander, the late Dr, 89, 95
Albuminuria, Treatment of Acute and Chronic, 348
Allarton's Lithotomy Operations, 403
Alum, Uses of, on Bougies in Strictures, 7
Amaurosis, Hysterical, 55
America, Quackery in, 56
Ammonia, Therapeutic Effects of, 369
Amputations, Acupressure in, 105
. . . . . Comparison between the respective Merits of, in the Leg and Ankle-joint, 116
Anatomical Museum seized at Leeds, 23
Aneurism, Treatment of, by Compression, 232
Anæsthetics, a Manual of, Theoretical and Practical, 355
Anæsthesia during Sleep, 423, 451
Antecedents of Brother Prince, 447
Anthrax, 55, 347
Apothecaries in Ireland, 198
Appointments, 14, 32, 48, 64, 80, 97, 114, 131, 147, 165, 183, 198, 217, 235, 253, 271, 288, 301, 316, 325, 362, 379, 397, 414, 433, 452
Army Medical Warrant, 425
Arrest of Hæmorrhage by Acupressure, 92
Arteries, Atrophy and Degeneration of the, 20
Arteries, on Wounds of the, and their Treatment by Surgical Operations, 33
Arsenic-eating, 407, 426
Arsenical Paper, Singular Case of poisoning by, 37
Artery, Diagnostic Value of Murmur in the Pulmonary, 104
Articulation, Treatment of Hip-joint by Excision of the, 168
Artificial Eye, its Advantages, 292
Army Estimates, 412
Ascarides, Cure for, 7
Asphyxia Neonatorum, 340
Atheromatous Expression, 349
Auscultatory Sound produced by the Action of the Heart on a portion of Lung, 137

Badly-comminuted Fractures, on, 309
Baines on the Comparative Properties of Human and Animal Milks, 212
Baker-Brown on Enucleating Uterine Tumours, 177
Baker's Reply to Mr Hinton, 302
Balanitis, 347
Bar of Lead cut out of the Stomach, 286
Bath Buns, 9
Belladonna for the purpose of destroying Adhesions, 311
Birch on Oxygen in the Treatment of Disease, 77
Birmingham and Midland Counties Medical Registration Society, 234
Buchanan, of Dr M. S. Glasgow, 451

BIRTHS :
Anderson, 63 ; Armstrong, 287 ; Barrett, 163 ; Barker, 378 ; Bennett, 14 ; Birch, 63 ; Caldwell, 233 ; Champneys, 197 ; Chambers, 413 ; Cobbold, 287 ; Cockerton, 63 ; Crisp, 113 ; Crossby, 341 ; Daniell, 378 ; Diver, 163 ; Ellis, 413 ; Jones, 413 ; Hayne, 80 ; Hewitson, 113 ; Hope, 287 ; Littlejohn, 63 ; Matthews, 113 ; Meldola, 413 ; Nobbe, 233 ; Palk, 287 ; Parsons, 31 ; Pearse, 63 ; Pesket, 341 ; Pinninger, 31 ; Reed, 145 ; Smallman, 287 ; Summers, 378 ; Thompson, 80 ; Times, 31 ; Todd, 14 ; Wake, 103 ; Watts, 63 ; Wood, 197

Bladder, Great Importance of early Diagnosis and Treatment for Stone in the, 35
Bladder, Stone in the, Difficulty in detecting it during Life, 35
Bladder, Calculus of the, 35
Blennorrhagia, on the Treatment of, 66
Blow of the Eye from a Piece of Timber, &c., 275
Bone-setter, Verdict against a, 139
Bonillaud on Diseases of the Brain, 1
Bowman on Injuries of the Eye, 65, 99, 131
Brain, Case of Extensive Injury to the, 394
Brain, Diseases of the, 1
Braid on Hypnotism, 158
Brandy Practice of Medicine, 213
Bread, the Hygiène of, 10, 26, 42, 58, 74, 90, 103, 123, 144
Breast, Acute Inflammation and Abscess of the, 331
Brother Prince, Antecedents of, 447
British Museum, Scientific Departments of the, 197
Bryant on Clinical Surgery—The Injuries and Diseases of the Nervous System, 126
Burgess' Memoirs of W. Cullen, 26 75, 109, 125
Burgess' Memoirs of W. Hunter, 176, 191, 209, 262, 283, 336, 353, 372
Black Doctor, 25, 30, 41
Bread Manufacture, 58
Brodie, Sir B., on the Recent Admissions to the College, 335
Burton, Dr, of Brompton, 389

Cæsarian Section, Case of (Mother and Child saved), 94
Cæsarian Operation, Case of, 311
Cambridge Board of Guardians, 298, 301
Campbell, John, Esq., 323
Cancer Curable (Is) ? 8, 92
. . . . recurring after Ten Years, 11
. . . . Cures and the Public, 24
. . . . Dr Reed's Treatment of, 29
. . . . Curability of, 54
. . . . Cures and Curers, 126
. . . . Curing Quackery Exploded, 371
Cancer of Face, 202
. . . . of Lip, 202
. . . . of Tongue, 202
. . . . of Breast, 257
. . . . Diagnosis of — How the Cancer-curers make Fortunes, 318
Carpenter on the Relation of the Vital to the Physical Forces, 237
Cases, Notes of Six Non-cancerous, 29
Catacombs of Paris, 130
Cervix Uteri, Hypertrophy of the, removed by Ecrasement Linéaire, 6
Cervix Uteri, Severance of the, during Labour, 162
Chancre of Finger followed by Buboes on the Elbow and Axilla, 410
Cheltenham Protest, 41
China, Hospital Ships for, 63
China, Wounded from, 198
Cholera, 269
. . . . . in the East, 269
Chlorosis as a Cause of Venous Obstruction, 119

Chloroform, on the Mental Peculiarities, &c., of, 104
Chloroform, Clinical Remarks on the Use of, especially in Midwifery, 167, 273, 327
Chloroform, Death from Inhalation of, 207
Chloroform, 145
Cinchonia in Intermittents, 329
Circumcision, Incontinence of Urine cured by, 234
City of London Asylum, 139
Civil Service Estimates, 452

CLINICAL LECTURES.

Badly - comminuted Fractures, 309
Compound Fractures and their General Surgical Treatment, 219 291
Diseases of the Brain, 1
Epidemic Dysentery, 417
Extravasation of Urine, 81
Hepatic Colic, 225, 345
Injuries and Diseases of the Eye, 99, 131
Iron Chlorosis and Tubercles, 49
Some Rare Forms of Fracture of the Scapula, 115
Wound of Arteries, 33

CLINICAL SKETCHES.

Cancer recurring after Ten Years 11
Compound and Multilocular Cysts, 11
Fracture of the Base of the Skull, 18
Is the Trephine useful? 18
Median Lithotomy, 66
Multilocular Ovarian Dropsy, 11
Puncture of the Heart by a Needle, 51
Vesico-vaginal Fistula Operations, 401
Wützer's and Wood's Operations, 66

Clinical Record of Cases occurring in Hospital and Private Practice, 202
Clinical Lectures on certain Acute Diseases, 389
Clitoris and Nymphæ, Case of Hypertrophy of, 117
Closure of the Womb, 203
Coffee as a Diuretic, 132
College of Surgeons, Examinations at, 77
College of Surgeons, 43
. . . . . Recent Admissions, 175, 227
College of Physicians, 245, 299, 334
. . . . . New Diploma of the, 319
College Elections, 406, 425
Commissioners, Charity, and Dr Wall, 9
Compulsory Certificates, 191
Complex Heart Disease, 171
Consumption, Treatment of Pulmonary, 94
Consumption, Practical Observations on the Prevention of, 355
Consumption, its true Nature and Successful Treatment, 372
Cooper *v.* Methuen, 79
Convulsive Diseases, 171, 204, 240
Contributions to the Pathology of Dislocations of the Shoulder-joint, 451
Cordova *v.* Barker, 95
Corn-cutters, Memorial of, 263
Correspondents, Notices to, 14, 32, 48, 64, 97, 114, 131, 147, 165, 183, 199, 217, 235, 253, 271, 288, 306, 325, 343, 361, 379, 397, 414, 433
Coroners' Courts, 299
. . . . . in Ireland, 374
. . . . . and the Medical Relief Bill, 316
Cottage Hospitals, 208, 246
Coup de Soleil, 20
Cox's Notes and Comments on Practical Cases, 3
Criminal Cases, Court of Appeal in, 88
Critchett on Median Lithotomy, 66
Cross-births, Twins, &c., their Treatment, 195
Cullen, Wm., Memoirs of, 26, 75, 109, 125
Cystic Diseases of the Breast—Serocystic Growths, or Cysto-sarcoma, 328
Cystic Growth of Lower Jaw, 405

DEATHS:

NOTES OF LECTURES
DELIVERED AT THE
ROYAL COLLEGE OF SURGEONS.
By Professor HILTON, F.R.C.S., &c.

CONCLUSION.

Mr Hilton's concluding lecture (after a recapitulation of some of the general principles of rest already detailed, such as the necessity of observing Nature closely, and giving assistance to, rather than thwarting, the "Vis Medicatrix," very especially seen in these severe cases of disease of the upper part of the spine) branched off into the subject of "psoas abscess," including the general philosophy of opening abscesses as practised at Guy's. "If surgeons would only take the trouble," said the Lecturer, two or three times, "and open abscesses in the manner we do at Guy's—and, in abscesses of the scalp, if they would remember *rest* to muscles, and close the abscesses as we do, much good would be the result." Nor should certain abscesses in deep parts, such as about the neck or pharynx, where there are such strong fasciæ, or under the glutei muscles, or in the popliteal region, attended with restlessness and fever, be permitted to open of themselves; but an exploratory puncture or incision having been made, this is to be enlarged from within outwards, not in the opposite direction, as is usually done. [A remarkable series of cases of abscess of each of these four localities was here recapitulated, reflecting—it would not be fair not to admit—the very utmost credit (as we know it deserves) on the surgery of the Borough Schools. Once these troublesome deposits of purulent matter is released, the agitation, restlessness, and feverishness of the system subside, and the patient enjoys an interval of rest which helps the cure.] One of the previous cases, for instance, was a patient sent in by a surgeon, suffocated, restless, and agitated, to have the operation of tracheotomy (!) performed. A casual looker-on would call the case, perhaps, by the legendary term "diphtheria." The child was smothering; but an abscess had probably not been looked for at the side or back of the pharynx—an abscess fearful to behold, with the jugular vein in front of it, the carotid near at hand, and various other smaller vessels not far off! In place of tracheotomy, which would obviously have done no good or killed the child, Mr Hilton made out an abscess, and made also a puncture or incision, and through the groove of the director, passed into the lower part of what he took to be the abscess, drops of pus made their appearance. This puncture was enlarged from within outwards, by passing a cutting instrument like a pair of common small scissors down to the bottom of the groove, and opening it according to circumstances on its being withdrawn. The somewhat blunt edges do little or no harm to vessels, even if in their way; but a rough outlet is obtained for the contents of the abscess. "To plunge a bistoury into the abscess," said the Lecturer, "reads very heroic in books. Plunging must be something grand; but take care your patient has not his carotid opened, and you hurry him to destruction." In a case of abscess of the inner part of the pelvis or iliacus muscle, as well as we could catch Mr Hilton's observations, he attacked the abscess in the same manner from the outside, made a punctured opening somewhere about the gracilis or through the coarse thick gluteus, passed his grooved director deeply, and opened up the parts freely from the inside towards the outside. Rest to the constitutional disturbance is almost always the result of seeking out such abscesses, and opening them in this manner early. This case, too, was saved the utter mischief of this abscess breaking into the peritoneum or pelvis.

Abscesses of the coverings of the skull under the pericranium were next referred to, as giving rise also to much trouble of another kind, if not healed after they have been opened, or have opened themselves. The occipito-frontalis muscle and corrugators are so active, they prevent the parts filling up again. Mr Hilton has known cases remain uncured for more than twenty months, to the great annoyance of the patient; yet when *rest* of this muscle was secured, it has got well in so many days.

This plan of rest seems to be peculiar to the practice of Guy's also. The occipito-frontalis is very moveable, a broad musculo-tendinous layer; it covers the whole of one side of the vertex of the skull, from the occiput to the eyebrow, arising (as shown by Mr Hilton in one of the stereotyped school-day diagrams, impressed on every reader's memory) from the outer two-thirds of the line on the occipital bone and mastoid portion of the temporal, keeping up a perpetual series of movements, especially towards its insertion into the orbicularis palpebrarum, or region of the forehead, where it is particularly fleshy, as well as over the occipital region; and also loosely adherent to the pericranium, but tough and close enough to the integument. The secret seems to be, in abscess cases, to tie down the occipito-frontalis by strips of diachylon plaster, so as to secure perfect rest of this muscle; then a nasty ulcerous opening, with the often absurd term "strumous" applied to it—an opening draining away pus in pints, reducing the patient's constitution to a very low ebb, not on account of its being strumous, but on account of the surgeon not knowing how to cure it;—an ulcerous, unsightly, disgusting deposit of filth and corruption, in orthodox fashion, moralised over for months and months, almost as absurdly as salivary fistula, chloride of zinc, or cancer-quackery, takes it into its own hands to get well in a week. One case recited by the Lecturer, which underwent all sorts of this scientific delay (bungling!) as discussion as to "struma," which poured out pints and gallons of pus for a period of over two years! and was fast reducing the patient to struma, and then to the grave, like some of the orthodox cancer cases, got well in a fortnight by a little knack that any "dresser" at Guy's, or the hospital porter, could explain, of tying down the occipito-frontalis, as first described, by strips of adhesive plaster. The great principle which is overlooked in such cases is, according to Mr Hilton, that the walls of abscesses, notably those under the occipito-frontalis, require REST—absolute, uncompromising, absolute rest—in order that the delicate areolar tissue newly forming may not be disturbed. Slitting up a fistula at the side of the rectum acts in the same manner also, as giving rest to an abscess in that locality, or rather to the muscular fibres of the sphincter.

Professor Hilton terminated his most instructive course of six lectures by some hasty remarks on physiological *rest* as applied to parts in a state of disease. "Irritable ulcer," the opprobrium of dispensary and hospital surgery, was the case instanced. This ulcer will go on for months and months without indication of healing: all sorts of things are done, reminding one of the scene in the 'Tempest'—

> "You rub the sore
> When you should bring the plaster—ay, marry,
> And most chirurgeonly;"

but it does not heal, like the abscess under the occipito-frontalis; still the remedy is quite as simple. A portion of cutaneous nerve, the size of a head of a pin, is exposed at one point of the ulcer; snip this out, physiological rest is secured, and the ulcer heals at once. Rubbing the sore now keeps up no irritation, and plaster at once takes effect.

The Medical Officers of the Channel Squadron were recently entertained at a dinner in Edinburgh by the President and Fellows of the Royal College of Surgeons. The entertainment was intended as a professional and complimentary recognition by the Royal College of their brethren of the Naval Service. Advantage was also taken of the occasion to invite the militant Medical Officers of the Staff and Garrison. The chair was occupied by Dr Douglas Maclachlan. In proposing the toast of "the Medical Officers of the Navy," the President passed a high eulogium on the service. Dr Deas, C.B., replied in a most eloquent speech for the Navy. Dr Anderson returned thanks for the Medical Department of the Army. The evening was most interesting and agreeable, a large number of Naval and Military Medical Officers and most of the distinguished Civil Surgeons in Edinburgh being present.

CLINICAL REPORTS.

Fractures of the Skull with Depression. Ought they to be treated all alike, or with the Trephine?—Mr Gay, Mr Paget, Mr Erichsen.

It would be easy, by a reference to our hospital notes, to collect a very large—in fact, an unlimited number of cases of fractures of the skull treated either with or without the use of the trephine, especially the former. The general verdict, however, as regards this instrument, it is to be feared would be, that where it did not do only a very questionable amount of positive good—or, in other words, where the trephine was not superfluous—it did irreparable mischief. In physiological Germany, of late, a very earnest crusade has been preached against the use of the trephine; but in our English schools, more full of facts, we have been blown about by every wind of doctrine; every possible mode of ingeniously putting the *post hoc* for a *propter hoc* has been in use, to indue with a scientific appearance this very worst kind of surgery. The study of physiology has been progressing, but the practice of surgery as regards affections of the nervous system has stood still; even in the obvious fact of dislocations of the shoulder-joint it is now found we have, in the case of the trephine, been content to copy the directions often stereotyped in plates of our older manuals and books, but neglecting the very obvious book of Nature. A new idea has got abroad, that symptoms of compression alone are not so dangerous as they have been hitherto believed to be. We have similar phenomena in typhus fever, and every time chloroform is administered; but in each case the brain quickly regains its normal condition; it is just possible the older surgeons were frightened at what they did not comprehend. In the large number of old fracture cases an opening with a trephine at one side was made; but the traumatic mischief was probably at the opposite side of the skull, or there was a chink-like split through the base, which Mr Hilton would say should be left alone, as, of the two alternatives, active trephining, or absolute rest or do-nothing, the latter is preferable. As an essential part of the treatment of trephine cases, rigid antiphlogistic treatment (so as to obviate the dangers likely to arise from the operation itself) is much dwelt on by surgeons like Mr Quain—such antiphlogistic means as bleedings, external applications of ice to the head, &c.; but it is quite plain that if symptoms of compression arise from mere pressure of a small quantity of blood on the dura mater, these things may get quiet again, without the murdersome device of boring a hole into the head, like into a double Glo'ster cheese, on the chance of meeting this small portion of effused blood.

But it is often said, "Surely hospital statistics ought to teach us how or when to have recourse to the trephine, in bad fractures of the skull, with or without depression." Looking through recent clinical cases of this nature, nearly a hundred hospital cases in number, we find the appalling fact that about two-thirds of the patients thus operated on die of the combined mischief of the original injury and the trephine. Most happily, we do not see of late years the same amount of afflicting cases of depressed skull, with fractured bone and compression, that were common in the early part of this century. Bricklayers' scaffolding is now made of a more substantial kind, one chief cause of this comparative fewness of the cases; at least this is the only fortunate circumstance that Mr Skey can trace out why we do not see trephine cases almost every day in the extensive hospital practice of London, as we did a few years ago.

Some good surgeons recommend and employ the trephine either to remove the cause of compression, whether depressed bone, extravasated blood, or pus, and as an anticipatory measure to prevent inflammation by removing splinters or supposed splinters of bone; so that the trephine as a prophylactic, especially where it is every day used, as in the manufacturing districts of England and Scotland, has had a somewhat factitious value ascribed to it.

There seems little doubt that operations performed early by the trephine, like those for hernia, are the best; though the other rule has hitherto been perhaps too absolute, to raise depressed fragments at all hazards by means of

the trephine, if it cannot be otherwise done ; and this even though stertor, dilated and immoveable pupil, complete unconsciousness, &c., may not be present. It is said, with some degree of plausibleness, that though there be not very bad symptoms thus at first, it is impossible to say what may be the result, with probable sharp splinters of the inner table lying on the dura mater or blood extravasated. Yet the more cautious men of the present ask, how is this very much or at all improved by merely replacing one cause of inflammation or of bad symptoms by another? (*a*)

It would be easy, as already indicated, to enrich our "Clinical Reports" with a multifarious collection of trephine cases, with various lessons taught or arising from such cases; but the remarks just made will be sufficient. The following cases, however, are of interest.

Case I.—J. C., a child aged eight months, was admitted into the hospital under the care of Mr Gay, in August, 1859, for injury to the head. The case proved on admission to be fracture with rather marked depression of the skull, as there was in the centre of the left parietal bone a well-defined depression of the cranium, about 1½ inches long, and ⅛th inch in its deeper part. "The overlying integuments," says the note-book, "bore a mark of violence ; the child, it was said, had received a blow some twenty-five days before, but, except for a slight insensibility at the time, he seemed quite well for a fortnight ; then he began to be ill with diarrhœa, and a week before admission the poor child had a fit." To this succeeded curious nervous sawing movements of the right arm and leg. The child had another attack of convulsions also the day before admission, August 27. It was decided to-day to give chloroform (which would obviously be little needed, if at all judicious) if the injury to the skull were attended by effusion of cerebro-spinal fluid, or marked insensibility of any kind. (*b*) Mr Gay removed the greater part of the depressed bone by means of the trephine. The portion of bone removed presented a fissured ledge having a pointed extremity. It was very interesting to observe that during the time the child was under the chloroform the "sawing movements" ceased, and after it had passed off the child appeared much quicter; but the child died next day—it was the quietness of death. At the autopsy a depression was found in the hemisphere exactly corresponding to that in the skull. The dura mater and arachnoid were both healthy.

(To be continued.)

THE SPIRIT OF THE PERIODICALS.

The 'Medical Times and Gazette,' June 30th, opens with a continuation of Dr J. Y. Simpson's Lectures *On the Diseases of Women*. He treats especially of the diseases of the *Fallopian Tubes*, *i.e.*, displacements, hypertrophy, fibroid tumours, carcinoma tuberculosis, inflammation, hæmorrhagic effusions, and dropsy. We will extract some observations on the latter affection :

"*The Ætiology of this Disease.*—Several years ago Hooper and others showed that when the inflammatory process, stretching upwards from the vagina and uterus, came to affect the lining membrane of the Fallopian tubes in all their extent, it was extremely liable to be attended with the formation of adhesions at the fimbriated extremity, where the mucous and serous membranes run into one another. As a consequence of this tendency to adhesive inflammation at the free end of the tubes, we not unfrequently find one or other of them bound down to the sides of the pelvis, to the uterus, or to the ovaries, or even simply obliterated from the union of its serrated margins. When an ovary to which a Fallopian tube has become adherent is enlarged and dropsical, it may occasionally burst and discharge itself along the tube and through the uterus, as shown by M. Richard, who specially pointed out this as one of the most common channels through which ovarian cysts were at times spontaneously evacuated. Or we may have a periodic discharge of a watery or serous fluid from the uterus under another condition, viz. when a Fallopian tube has become completely obliterated at its free extremity, and so far constricted at its uterine orifice as to prevent the escape of its ordinary secretion until that has accumulated to such an extent as to overcome the resistance presented to its escape, as seems to have occurred in a case recorded by Frank. More frequently the constriction at, or rather towards, the uterine extremity becomes more complete and permanent, and the fluid becoming thus finally retained in the tube, a dropsical cyst is ultimately produced. We may thus have dropsy of the Fallopian tube brought on as a result, first, of inflammatory changes commencing in its lining membrane. But, secondly, the cause is at least as frequently to be sought for in changes produced by inflammation of its peritoneal covering and of the peritoneal surface of the contiguous organs, which we find to be one of the most frequent causes of the deformities and displacements of these several organs, from its liability to lead to the formation of adhesions between the neighbouring opposing surfaces. In the case of the Fallopian tubes, in particular, inflammation of their peritoneal surface has the effect of closing up the free extremities by binding them to the neighbouring parts, and also of causing the tubes to be folded or bent on themselves once or oftener. When the ordinary secretion of the canal begins to accumulate between any two of these points of flexion, a degree of compression is ere long produced, which speedily leads to the intimate union of the opposite sides, and hence to complete occlusion of the canal ; and in this way a temporary accumulation of fluid is converted into a permanent collection, and a dropsical cyst, or rather a congeries or chain of cysts, is developed.

"*Pathological Anatomy.*—When a Fallopian tube becomes dropsical in consequence simply of an inflammatory process in its interior, the resulting cyst is usually single, and one end of it is produced by the occlusion of the fimbriated extremity, while the other corresponds to that point towards the uterine extremity of the tube where it begins to become narrower before running into the substance of the uterus, and where, consequently, complete closure is more apt to occur. We more frequently, on the other hand, find the tube divided into a series of cysts, or rather of dilatations, where the morbid change is produced by adhesive inflammations, which cause the tubes to become convoluted on themselves, and the resulting cysts to be further indented, and divided by means of tight fibrinous bands passing over their surface. The contents of these cysts are usually clear and simple, like the fluid I have already shown you ; but not unfrequently the fluid is mixed with flocculent masses. The lining membrane of the cyst is subject to inflammation, and hence we occasionally find them containing inflammatory products, in some cases mixed with hæmorrhagic extravasations. The size attained by these Fallopian cysts, or hygromatous sacs, as they have been designated by Hooper, varies greatly in different cases. Sometimes the distended tube at its most dilated point is no wider than the small intestine ; not unfrequently the dropsical swelling is as large as the fist ; and occasionally, but rarely, it attains the size of the fœtal head. We may justly, I think, be allowed to be sceptical as to the correctness of these statements, or the carefulness of the observations of those who have recorded cases where the tumour was of much larger dimensions. When Munnik and Muralt, for example, relate that they have found respectively 110 pounds and 112 pounds of fluid in a single Fallopian cyst ; and when Harder and Desormeaux speak of cases where there were 140 pounds of fluid,—we can only suppose that these large quantities of fluid were contained, not in a dilated Fallopian tube, but in the cavity of a dropsical ovary. And if we call to mind how intimately adherent the Fallopian tube sometimes becomes to an enlarged and cystic ovary, so that it appears to be amalgamated with the wall of the cyst, we can easily understand how the two forms of disease should come to be confounded ; and we may well doubt whether even the thirteen pounds of water mixed with pus, which Bonnet says he found in a Fallopian tube, was not in reality contained in the cavity of an inflamed ovarian cyst.

"*Semeiology.*—Patients affected with dropsy of the Fallopian tube complain of many of the same symptoms that we find associated with ovarian tumours in the earlier stages of their growth. There is an uneasy sense of weight in the side affected, and a feeling of pressure on the limb. Usually the limb is rendered more or less numb from the pressure of the tumour on the nerves passing through the pelvis, and I have sometimes seen a patient rendered extremely lame in consequence. In some cases it acts chiefly upon the bowels, keeping them loaded, and the patient uncomfortably constipated. More rarely there is a certain degree of dysuria. In almost all the cases that have come under my observation, the patient has been sterile, even when the tube of one side only appeared to be affected. That the ova should fail to be conveyed by the tube of the affected side, follows as a matter of course from the morbid condition of the canal ; and perhaps the change in the position of the pelvic organs, produced by the pressure of the cyst, may have the effect of preventing the uterus from receiving the ova developed in the ovary of the opposite side. But none of the rational symptoms, nor all of them combined, will enable you to recognise the nature of the case, and to make a correct

"*Diagnosis of Fallopian Tube Dropsy.*—In practice this form of disease is usually altogether overlooked, or is mistaken for some other kind of tumour. The lady from whom the fluid I have shown you was withdrawn, came to this country from Australia after having sought relief in vain at the hands of several practitioners in that colony, and since her return to Britain she had consulted a number of medical men, all of whom differed as to the nature of her disease, and all of whom supposed it to be seated in the uterus or left ovary. One gentleman, who has himself written about dropsy of the ovary and Fallopian tube, after examining this patient, told her that her trouble lay entirely in the mouth of the womb. When I first saw her, I could not come to any very definite conclusion as to the nature of the case. I could only determine by vaginal examination that there was some kind of tumour in the left side of the pelvis, for the rectum was at the time so loaded with fæces as to prevent all possibility of a thorough investigation of the character of the swelling. Having taken the precaution to have the bowels effectually cleared, I was enabled at my next visit to come to a more distinct and definite conclusion regarding it. For, by vaginal examination, I could discover the firmish fluctuating tumour at the left side of the uterus, and by introducing the second finger of the same hand into the rectum, and placing the other hand above the pubis, I could make out quite distinctly its situation and its relation to the neighbouring parts. It so happened that the abdominal walls in this patient were soft and very much relaxed in consequence of her having had a child sixteen years ago ; and by examining simultaneously with one hand above the pelvis and two fingers of the other introduced into the interior, I could anatomise, as it were, the pelvic organs, and make out their conditions and relations. In this way I found the uterus to be perfectly sound and normal, while to the left side of it lay a tumour capable of being moved independently of the uterus, and which, from its painless and fluctuating character, could only be of a cystic nature ; and as this cystic tumour was elongated in its shape, widening towards the outer extremity, and indented at several points as if folded on itself, I had no hesitation in setting it down as a dropsical dilatation of the left Fallopian tube. There were only two other kinds of

(*a*) Stromeyer, who has worked an entire revolution in this subject (though once himself an advocate for the trephine), now states it as his conviction that it kills nearly every patient! Sir G. Ballingall has a series of cases of injuries of the skull in battle, all treated by the orthodox plan of the trephine ; but suddenly sixteen cases of recovery occur, which Stromeyer was curious to examine into, when he found Sir G. Ballingall's portion of the army was flying before the enemy in full retreat, and he had lost his trephines in the battle!

(*b*) The subject of "anæsthesia during sleep," by the way, which has recently "woke up" in the minds of a few persons as a discovery, is not at all new ; but, for obvious reasons, from good taste, it has been kept in the background by such writers as Snow, Murphy, &c. Except in the cases of children, it is not safe nor advisable, nor should it as a matter of public propriety, under legislative penalty, be permitted at all. Such, at least, is the opinion of these writers and Dr Kidd.

tumour with which it could have been confounded —viz. 1st, a cystic degeneration of the ovary in an early stage; or, 2nd, one of those thin-walled cysts which we sometimes find attached to the fimbriated extremity of the Fallopian tubes, or growing from the outer margin of the broad ligament, and which are produced by an accumulation of fluid in one of the unobliterated tubes of Gærtner. But both of these forms of cystic tumour have this difference in common from the dropsical dilatations of the Fallopian tubes, that they are at once both more rounded in their form, and more smooth and equable in their outline. The tumour formed by a commencing cystic degeneration of the ovary differs further from this dropsy of the tube, in that it is more unyielding and elastic, containing, as it does, at this early period, more solid substance than serous cavities. The other kind of cyst, again, to which I have referred, is rarely found of such large size as to come under the notice of the practitioner, for ordinarily it is found after death of about the size of a pea, with a thin elongated neck or pedicle, and the largest of them almost never exceed the size of a hen's egg; while, from the quantity of fluid which I have shown you, you will be able to see that in this case the tumour must have been at least three times that size. From its size, therefore, and its situation, its elongated and somewhat conical form, its wavy, sinuous outline, and its power of being moved independently of the uterus, I believe I am justified in concluding that I have here had to do with a case of dropsy of the Fallopian tube. I know not in what other light to regard it, or what other kind of cyst it well could be. I ought to add, that the very nature of the fluid, which escaped through the exploring-needle which was introduced for its evacuation, confirms me in my belief that this diagnosis is correct. For the fluid in a small ovarian dropsy, with which form of disease assuredly the cyst in question was most likely to be confounded, is usually too viscid to allow of its easy escape through a narrow canula; while in this case the clear evacuated fluid rushed through the small hair-like tube of the exploring-needle in a full, free stream."

Dr Elliotson contributes to the same journal a paper on *Urethral Rheumatism and Ophthalmia*, which we will quote in our next Number.

Mr Henry Smith reports a case of *Aneurism of the Popliteal Artery*, in which compression was first employed, but appearing to fail, the superficial femoral artery was tied: the patient appeared to go on well, but, after the wound had healed, the aneurismal sac burst and suppurated. Mr Smith remarks upon the case:

"This case is not brought forward for the purpose of proving anything against the use of compression in the treatment of aneurism; for although a pretty persevering employment of it for upwards of a fortnight did not result in the cure of the disease, there was not the slightest ill effect produced, save some temporary pain and a slight tendency to inflammation of the sac, and it is impossible to say that ultimate consolidation of the aneurismal tumour might not have resulted from a further continuance of the treatment, had the temper and the circumstances of the patient allowed of it. I say this, however, doubtingly, for Mr Fergusson, who kindly saw this patient with me at first, and had not seen him again until the vessel was tied, was of opinion that the aneurism had increased in size in that interval. Be this the case, however, or otherwise, not only was there no mischief produced by the employment of compression, but I believe it did good by leading to an increased activity in the collateral circulation, by which means mortification or any tendency to it was obviated. I should suppose that in about one-half the cases where the superficial femoral artery has been tied, and all the patients much younger than this one, I have seen gangrene of the leg or foot ensue; and one naturally felt anxious about such a contingency in a person nearly sixty years old and of damaged health. Although cases are now and then met with where the same kind of operation has been performed in persons as old, or even older, without the loss of their foot or leg from gangrene. A little time since Mr Fergusson placed a ligature upon the external iliac artery of a gentleman aged fifty-six without any such result, and in one of two cases where I tied this same vessel with success the age of the patient was sixty-two. I should have tried the flexion treatment in the case just narrated, but the aneurism was so large, and an attempt which I made to bend the knee was attended with such pain, that it was out of the question to adopt that admirable yet simple means of cure.

"The inflammation and bursting of the aneurismal sac, which took place subsequent to the separation of the ligature, and which retarded the recovery of the patient for some weeks, could scarcely have been in any way influenced by the previous application of pressure, although the fact of its occurrence might be pointed out by those who are adverse to this mode of treatment as an argument against it. It is true that, at one period during the compression, there were some threatenings of the sac inflaming; but these symptoms had entirely subsided, and I question much whether the subsequent mischief was not solely produced by the patient, in his haste to get well, making violent efforts to straighten his knee. It is a very fortunate circumstance that the bursting and inflammation of the sac did not take place before instead of after the application of the ligature; for, had this been the case, the man must undoubtedly have lost his leg; whereas, the vessel having been secured, the necessary incision into the tumour could be effected with perfect safety."

Dr Eben Watson reports in the 'Medical Times and Gazette,' June 23rd, seven cases of *Vesico-Vaginal Fistula*. After reciting the cases, he makes the following observations on the details of the operation:

"*Remarks.*—1. *The Position of the Patient during the Operation.*—A few trials will, I think, convince any one that the position on the knees and elbows is that in which the best view of the fistula can be obtained, and, therefore, the best for operating on it. But it would be very difficult for the woman to maintain this position during a painful operation, and it would be quite impossible under chloroform. I, therefore, always have my patients fixed on a table of convenient height, the pelvis being raised on a firm support, while the shoulders are allowed to lie on a pillow on the table itself. The head is supported in the hands of assistants, who give the chloroform. Thus the patient is prevented from moving, and the cautious administration of chloroform is rendered safe by the freedom with which the respiratory organs are allowed to play.

"2. *Speculum.*—The best speculum for vesico-vaginal cases in use at present is Dr Sim's bent duck-bill speculum; but I think it might be greatly improved. For instance, in many cases the vagina is very loose and wide, and I have found it necessary to employ lateral retractors as well as Sim's speculum. Now, side pieces might be added to the speculum itself. Again, the curve at the end of the speculum seems to me objectionable; for it prevents the operator seeing the relation of parts at the upper portion of the vagina. The os uteri is pushed up, and a great strain is put on the vagina, whereby the lips of the fistula are inconveniently separated. Above all, the necessity of an assistant's holding the speculum might be done away with by the adapting a spring to the instrument, which would fix it within the vagina or on the sacrum.

"3. *Operation.*—The first thing the operator has to do, and in my opinion the most important in this part of the proceeding, is to get a good hold of the anterior inferior lip of the fistula. Most operators have recommended that this should be done by means of a small hook; but this gives a very insecure hold of the part—it is easily lost during the cutting of the margin, and even in fixing it; at first, it often slips, and thus blood flows, obscuring the view and impeding the future steps. I have always used, and very strongly recommend, a pair of spring forceps with vulsellum points and a handle, so as to elongate and facilitate the use of the instrument. Its insertion is almost bloodless, and needs only to be once repeated in the largest fistula; only one catch for each lip being necessary. A fine straight bistoury—a tenotomy-knife is admirably suited for the purpose—is then inserted in a slanting direction first on the one, then on the other side of the part, seized by the forceps, and made to cut out the margin of the fistula to the very extremities. These two incisions are then united below the forceps points so as to complete the paring of the inferior lip.

"The upper lip is next seized in a similar way, and if the fistula is not very large, by firmly raising the part to be cut, the same straight bistoury may still be used on it from below upwards. But, if the fistula is large, it will be more convenient to change the knife for one the cutting part of which is bent at an angle to its stem, and which may be double-edged to save changing again. This knife was figured by Dr Simpson in the 'Medical Times and Gazette' for January 8, 1859. The upper lip of the fistula is thus carefully pared to meet the former incision at the extremities of the fistula. It is an exceedingly satisfactory thing to cut out the margin of the fistula in one entire ring, and I have accomplished it more than once. This is not a mere feat of manual dexterity, but gives the best assurance that the cutting part of the operation is throughly done.

"The next step is to introduce the sutures, which I think ought to be of silver wire. This is best done by the tubular needle invented by Mr Startin. It is of great importance that a good hold be obtained for these stitches, and also that they be made to pass close to, but not through, the mucous membrane of the bladder. The raw surfaces are thus fairly brought into apposition, and from the slanting nature of the pared edges, they are pressed together with special firmness on the side towards the bladder. I think it satisfactory to twist the sutures and to examine that the wound is properly in contact before applying the plate over them.

"The plate which I recommend and employ was invented by Mr Hilliard, instrument-maker to the Infirmary, and was described by me in the 'Lancet' for March 5, 1859. It is made of lead, and has small tubes or nipples instead of the holes of Bozeman's button. These tubes may be easily compressed, and thus fasten the wires.

"In the 'Lancet' for December 10, 1859, Mr I. B. Brown has published a paper 'On Vesico-Vaginal Fistula; illustrating a New Mode of Operation.' Now the only novelty in his 'new mode' is the use of what he calls 'clamps.' These are small bars of lead, with nipples on their backs for fastening the wires. But it will be quite evident at a glance that the clamps are neither more nor less than fragments of Mr Hilliard's plate. In fact, if it is cut through between each pair of nipples, as I did before my clinical class last winter, you get a series of clamps ready made. The original idea of having compressible tubes or nipples for fastening the wires was undoubtedly Mr Hilliard's, and not Mr Baker Brown's; but the latter gentleman may certainly lay claim to whatever merit there may be in clipping the plate of the former into shreds, unless Mr Startin's claim to priority, which seems undeniable, be admitted. (See 'Medical Times and Gazette,' April 21, 1860.)

"I believe that such mutilation of the plate destroys its value as a mode of fastening the sutures; for, when entire, it acts beneficially by steadying the parts, and also by adhering very closely to them and excluding both air and discharges from the wound. It seems to me to act like a boy's sucker, and thus to bring the wound very nearly into the position of a subcutaneous one, which, everybody knows, heals more readily than any other kind.

"Such are, in my opinion, the advantages of the plate, but its use is not absolutely necessary for success. I have twice dispensed with it, and yet the cases did well. Still I should recommend its employment, as a general rule, for the reasons already stated, and shall myself always use it unless there is some contraindication.

4. *Treatment after the Operation.*—The patient should lie in bed on her back, with her shoulders well supported by pillows, so as to incline her body at an acute angle with the bed. Her knees should also be supported by pillows in the semi-bent position, and between her thighs should be placed a vessel for the reception of the urine as it drops from a catheter lying in the urethra. This may either be a bent leaden one or a gum-elastic catheter. Finally, the patient should be soothed with opium, in some form which agrees best with her; but I would urge the importance of not over-doing this part of the treatment. The large quantities of opium recommended by Dr Bozeman have not been found necessary in my cases, and

in one they were productive of disagreeable consequences. On the eighth or ninth day after the operation the plates and the stitches should be withdrawn. A good light, and much patience, are needed for this operation. In fact, its difficulty has been undervalued. I have sometimes failed to extract all the stitches at the first attempt, and can testify to the safety of leaving in a stitch for a few days longer than the rest. By that time it will have loosened, and may be felt in the vagina, and extracted with a pair of common dressing forceps, which is the instrument best suited for the purpose. The bowels should now be opened as quickly as possible, first by enemata, and then by medicine. I generally use the compound colocynth pill. The opium is gradually given up, the catheter is also laid aside by prudent degrees, and the patient, in a fortunate case, is cured of her distressing complaint in little more than a fortnight. The completeness of this cure, when accomplished, could not be better proved than by my cases; for in one of them the patient had an abortion only a few days after the plate was removed; in two others the women have miscarried, since the operation was performed, in the eighth month of pregnancy, and in one a living child has been born, at the full period of utero-gestation, without the slightest injury to the cicatrix.

"*Amount of Success.*—Mr Baker Brown, in the paper to which I have already alluded, states that he has had 'a greater amount of successin operating for vesico-vaginal fistula than that yet published by any other Surgeon.' Now he certainly has had a great many cases of that lesion under his care, and therefore it may not be uninteresting to inquire into the proportion of cures to failures among them. I think we are entitled to do this since Mr Baker Brown has boasted in the above terms of his great success, and also because Mr Baker Brown has devoted his special attention to the diseases of women requiring Surgical operations. To his writings, therefore, Surgeons naturally look for encouragement or discouragement in the performance of operations within the domain of his speciality. I have not been able to discover the records of all Mr Baker Brown's twenty-seven cases, but I have read his own reports of nineteen cases in the following repositories, where they may be consulted by any one:—1. In Mr Baker Brown's book 'On some Diseases of Women,' four cases are recorded at pp. 100 to 110. 2. In the 'British Medical Journal,' No. cxviii., four cases are recorded at pp. 267 to 269. 3. In the 'Medical Times and Gazette,' No. 407, three cases are recorded at p. 398. 4. In the 'Lancet,' No. xiii. p. 322, one case is recorded; and in No. xxiv. p. 581, seven cases are recorded. I think that these nineteen cases, taken just as I could find them, will exhibit the success of his practice sufficiently without my undergoing the labour of any further search for his cases.

"Now, of these nineteen patients two died; one apparently of pyæmia (Treatise, p. 108), the other of frequent hæmorrhages ('Lancet,' No. xxiv. p. 583). In other two cases (Treatise, pp. 104 and 110) the fistulæ remained open; so that *four* out of the *nineteen* cases may be considered as ultimately failures. Still, it will be said, there were *fifteen* cases ultimately cured; and this is a great amount of success in dealing with what Mr Baker Brown rather oddly terms 'a difficult lesion.' But this is hardly the way to look at the matter. It is not that there were nineteen operations, and fifteen of these successful. Far from it; for in many cases the operation was frequently repeated before the cure was *ultimately* arrived at. In one case, for instance, the poor woman was operated on twenty-five times before the fistula was closed ('British Medical Journal,' No. cxviii. p. 267); and, while we admire the courage of the patient, it must be admitted that the operator failed twenty-four times in this one case; yet it counts simply as a cure in Mr Baker Brown's statement of his great success. It may, indeed, be enough for philanthropic purposes to look at the number of *ultimate* cures; but certainly, in trying to ascertain or to demonstrate the successfulness of an operation, we must compare the number of times it has been successfully performed with the number of times in which, when performed, it has failed to accomplish the intended result. Now, in this latter point of view, the statistics are as follows:—In the nineteen cases above referred to, Mr Baker Brown operated seventy-one times, and succeeded fifteen times. In other words, he was successful fifteen times, and failed fifty-six times.

"This 'amount of success' hardly warrants his boast, in my opinion, and perhaps does not give very much support to the cause of specialties. For my part, I cannot see any good reason why the 'blood-red tape' should surround the department of Surgery to which the operation for vesico-vaginal fistula belongs. Any Surgeon who is accustomed to operate on the other regions of the human body may perform this operation if he possesses good eye-sight and some steadiness of hand as well as of purpose. Of course it must be supposed that he understands well the various steps of the procedure; for I am convinced that it is by misapprehending some of these that failures occur at all. Too much importance is often put on the cutting part of the operation, and too little on the others, especially on the insertion of the sutures. A little care is necessary in regard to both points; but, if such care is bestowed, the Surgeon—whether obstetric or ordinary—may almost surely reckon on success. I myself have not once failed; for, as I have already stated, only seven cases have as yet been under my care, and in all of them I have closed the fistula at the first operation."

Mr Barwell contributes, in the 'Lancet' of June 23rd, an article on the *Scrofulous Diseases of the Synovial Membrane of Joints*, from which we now insert our promised quotations:

"The stages in which it appears desirable to divide scrofulous diseases of the synovial membrane are these:

"First stage.—That in which the synovial and subsynovial tissues are alone involved.

"Second stage.—That in which the cartilage and the bone become involved.

"Third stage.—That in which the new tissue either begins to consolidate into fibrous membrane, or to degenerate.

"In the previous paper on this subject, the true nature of the jelly-like growth was explained. The symptoms of the disease are so well known, that we need enter no further into them than is necessary to point out the differences between this and the next stage. The disease is generally attributed to some slight accident, just as scirrhus is usually ascribed to some such cause; but there is no doubt that it generally arises, without any external provocative, as a painless tumefaction of the joint; and frequently this swelling is accidentally discovered after it has existed for several days, or even weeks. According to my experience, this form of commencement is that which marks the more distinctly strumous and intractable form of the malady; but in all cases, after a certain time, there supervenes pain, which is not severe, but of a dull, aching, and, as many patients complain, of a bursting character, increasing towards evening, when the person has been some time erect, and decreasing when the limb has reposed in a horizontal position. The form of the swelling is peculiar: not like that of acute synovitis, in which the position of ligaments is well marked; but, on the contrary, is characterised by want of shape. It tends to the round or oval form (the former most in the knee, the latter in the elbow), and conceals all the anatomical points and the configuration of the part, hiding the points of bone, ignoring the position of ligaments. The shapeless mass is soft, doughy, and quaggy; it does not fluctuate, but, on account of its extreme softness, presents a sensation which comes very close to fluctuation; it feels as though the material beneath the skin were not a fluid, but a semi-solid—a jelly, as in fact it is. The temperature of the part is only slightly increased.

"This stage may continue for an almost indefinite period, but at some time the cartilages will become involved, and the second stage commences. The cartilages are not ulcerated by any eroding action of the synovial membrane, although the granulation which takes place from the internal surface overlaps them to more or less extent; but the inflammation spreads to those structures, and they undergo precisely similar actions—namely, cell-growth. (See my paper on the 'Nutrition, Inflammation, &c., of Articular Cartilages,' 'Med.-Chir. Review, Oct. 1859; and that, also, on the 'Relation between Synovitis and Ulceration of Articular Cartilage,' in the 'Edinburgh Medical Journal,' Feb. 1860.) This action, then, is an inflammation—*i.e.*, hyperaction of the nutritive machinery of the tissue, such as is the true nature of all inflammations. But there are no nerves in the cartilage to be affected by swelling or other result of its diseases; hence ulceration of their structure may, under certain circumstances, take place without giving rise to any painful symptom. We find such a breach of tissue in old persons who gave no sign of disease during life; but these ulcerations are not produced by an active inflammatory disease which has spread from other structures to the cartilage—indeed, they are simply degenerations, and we find all the neighbouring parts healthy. Inflammation of the cartilages, on the contrary, is a painful disease, and produces certain symptoms which mark the second stage, although, as the pain is not situated in the cartilage (which has no nerves to feel pain), it is probable, if not certain, that ulceration has advanced some distance before we have any means of detecting its presence.

"Mr Toynbee pointed out, in 1841, certain vessels which are formed during fœtal life in the epiphysal cartilage, and which, after ossification is complete, become the looped and anastomosing nutrient vessels of the cartilage. These vessels are situated beneath the articular lamella, and become, as I first pointed out, engorged and hyperæmic during this second stage of synovitis; and it is this engorgement that produces the set of pains which are characteristic of cartilaginous inflammation. The inflammation begins by cell-action in the cartilage, which produces the hyperæmia as a necessary sequence of demand for more nutriment; hence, when the hyperæmic pains come on, the inflammation is already established. The dull, aching pain, and that feeling of distension which is the pain *par excellence* of a strumous synovitis in the first stage, becomes now exchanged for a sharper, more severe form of aching, which is comparable to the pain of toothache; but, above all, this second stage is to be distinguished by starting or jumping of the limb when the patient is dropping off to sleep. The first appearance of these pains is the first certain sign that the cartilages are ulcerating. There is a symptom whereon much stress has been laid, but which I believe to be of very doubtful import—viz., tenderness on pressing the articular surfaces together. I have seen four cases in which this symptom was altogether absent up to the moment of removing the part, and yet have found extensive disease of the cartilage. Starting of the limb was present in all these instances. I have seen one case in which there was tenderness without cartilaginous ulceration. Hence this symptom is not to be relied on as proving that the cartilages are diseased; but I am not as yet prepared to say what exact condition, if any, it does indicate.

"The supervention of starting of the limb is a much more reliable sign that the second stage of strumous synovitis has commenced, which, like the first, is with regard to time indefinite in its duration. It is marked by more severe symptoms; pus forms more abundantly in the cavity, and probably finds its way outwards; a more or less extensive portion of the cartilage and its articular lamella disappears; the cancellous cavities are laid open towards the joint, and from then begin to sprout granulations like those developed from the synovial tissue, while from the wear and tear of the disease hectic supervenes. The joint therefore is, as a frictionless apparatus, destroyed, and to speak of its destruction as a further action seems absurd; but let it be considered that the aim of the disease from the very first has been to fill up the cavity with granulations; even the destruction of the cartilage and laying bare the cancelli have this object. If it succeed ultimately, we do not call the joint destroyed, although it be immovable from anchylosis; but actions may take place, whereby the new-formed tissues and the neighbouring parts enter into the way of destruction.

"The third stage consists of actions, either of which may be singly present, or either may predominate: the one is further development, the other degeneration of the granulations. Both may commence at any period during the course of the first two stages; but degenerations hardly occur, except when the disease has lasted a considerable time. They are of many sorts, but it would detain us too long to follow them out here.

Suffice it to say that tubercle in the so-called tubercular synovitis (a rare disease) is thus produced; the tubercle is not a cause of the inflammation, but is formed from a product of that action. Abscesses in the periarticular tissues are produced by change of the granulation-cell into the highly-generative pus-cell. Fatty degeneration is frequent, and produces death of the degenerate and suppuration of the surrounding portion. If these take place in the tissue which springs from the bone, and occupies the cancelli, masses of the osseous tissue may slough and come away. With all this the disease spreads, abscesses form amongst the deep muscles, and the inflammation runs along the medullary canal.

"The further development consists, as we have already seen, in an interstitial change of the cells into fibre-cells and fibres, and ultimately into new coarse areolar tissue. If this have been perfected during the first stage, the joint will be restored without further damage than a certain amount of thickening and difficulty of movement. If in the second stage, the state left will depend on the more or less advanced condition of that stage. If the cartilage have disappeared, the granulations from the bone and those from the synovial membrane are intermingled, and fill the cavity; they will, on becoming fibrous, form a strong but flexible bond of union between the bones—a false anchylosis; and if after a longer period the fibres ossify, a true anchylosis will be established.

"Thus the condition in which this process will leave the joint, varying from a mere inconvenient thickness to utter stiffness, depends upon the stage to which the malady had previously advanced, and our endeavours must be therefore directed to bring on the developing action as early as possible; to convert the already-formed granulations into fibrous tissue, and to prevent the further spread of the granulating process."

The 'Lancet' opens with a continuation of Dr TWEEDIE's Lectures on *Fever*. Mr BARWELL continues his subject in the present number. We quote the article:

"There is no doubt that even the most chronic, insidious, and painless form of this complaint is, at least in the first stages, an inflammation; and hence, the joint must at once be placed at absolute rest. Some form of counter-irritant should be employed, and proper internal remedies to ameliorate the constitutional condition. This is not the place to enter into the reasons that would cause the choice of one counter-irritant more than another; but it is desirable to point out the disadvantages attending a certain plan too much in vogue. A patient applying with this disease is generally ordered a splint—perhaps leeches, or a blister; and after a time an issue is made, which is kept poulticed for a month or two, discharging all the while. Now it is evident that nothing can more conduce to the spread of the new tissue, whose encroaching growth constitutes the disease, than warmth and moisture, unless it be an indolent suppurating and granulating sore, such an issue becomes a week or ten days after its application. If issues are thought desirable, they should be either kept open for only a short time after the separation of the slough, and another be made, or they should be touched again with the caustic potash, and so kept irritable. The former method has its disadvantage in the breadth of surface destroyed; the latter, in the depth to which the sore penetrates; and both in the very great pain produced by the treatment. Some persons have believed, and do still believe, that the amount of benefit is proportionate to the pain. This is a mischievous idea, since it leads to a cruel line of practice. The notion, no doubt, was obtained from the observation, that issues benefit mostly at first, and that in a short time their action becomes null, or absolutely injurious, since the constant discharge weakens the tissues, and tends to produce cell generation all around.

"A much better, and a much less painful plan than the issue, is the actual cautery: it is one which I would wish to see much more generally used; but its application requires some practice, skill, and knowledge, since an unskilful use is apt to produce too great a destruction of skin, too deep a furrow, or other evils instead of benefits. If the means be judiciously employed in properly-chosen cases, its action is marvellous; and now that chloroform prevents the immediate pain, the objections which caused it to be disused in England have disappeared.

"The iron which I employ for this purpose is known as Rust's: it is simply a three-sided prism, mounted by one of its oblong facets to a curved handle. The edges are slightly blunted. An iron of this shape has bulk enough to retain the heat a sufficient length of time, and yet presents a small edge. Two irons ought to be used, as a white, not merely a dull-red, heat is desirable, and thus a change of instruments is necessary. While the patient is being placed under the influence of chloroform, the joint to be cauterized should be protected by strips of plaster, or of moistened lint, a good inch or an inch and a half broad, leaving narrow intervals between each, where the lines of firing are to run. When anæsthesia is fully established, a white-hot iron is to be slowly, and with gentle pressure, passed three or four times along each space, until the skin be turned into a yellow-brown horny substance. Let it be particularly observed that the rays ought not to be nearer than an inch; the skin must not be divided by the iron; the heat must be sufficient to char the skin. This mode of using the iron was called by Percy, ('Protechnie Chirurgicale,) 'cauterisation transcurrente.' We might name it linear cauterization. Rust, of Vienna, and Bonnet, of Lyons, employed it with great success. My own experience warrants me in speaking of it very highly. In the first place, it gives no pain whatever at the time of application, and when the effect of the chloroform has disappeared, still no pain from the cautery can be felt. Compare this with the torture produced by the potassa fusa, under which the patient will writhe for hours after the application. But not merely is the hot iron painless; it absolutely relieves pain. I applied it in a case of hip-joint disease, in which the patient was suffering so much that he dared not move; his face was anxious, and his nights all but sleepless. After he had recovered from the chloroform, he was laughing, talking, moving about in his bed, and wanted to get up. In a case of knee-joint affection, the same change from pain to painlessness followed the use of the iron, and the patient is now able to walk. The narrow charred lines made by the cautery begin to separate in from five days to a week, and come away between the fourteenth and twenty-first day. They should then be healed as quickly as possible.

"The value of pressure in strumous synovitis cannot be too highly estimated, if the proper cases be chosen for its use; such, for instance, as those in which the swelling is soft and sluggish, in which a bursting pain is felt, and in which a sensation of cold is experienced. Dr Scott, of Bromley, first used this plan with considerable success; he applied mercurials to the joints, and over them strapping plaster. The value of the treatment lies in the pressure. Mercurials are of little or no help; in strumous cases I believe they are even injurious. The *modus operandi* of this agent I believe to be, simply preventing the cells, through want of room, from generating afresh, and, therefore, constraining their organizing force to act in the production of tissue from the cells already formed, or in the absorption of those unfit for this purpose. I know no means at all comparable in their power of resolving strumous synovitis to the use of the actual cautery followed by pressure. If, for instance, on the knee-joint the lines have been drawn parallel to the axis of the limb, they will, on healing, contract very considerably like all scars of burns; and if to the pressure thus produced be added that of strapping plaster, an almost irresistible power of resolution will have been gained. Indeed, unless the case be too far advanced, or too much supported by a vitiated constitution, it will yield to this treatment in a few weeks. The following case shows the value of this method:—

"Jane S——, aged six, a pale, strumous girl, has been suffering for twenty months from pain and swelling of the left knee, and was admitted into Charing-cross Hospital under my care (through the kindness of Mr Hancock), Dec. 9th, 1859. The knee is a good deal bent, the joint being round and shapeless; the child cries when it is touched, and when any attempt is made to move it.

"Dec. 31st.—I drew four striæ of linear cauterisation, one on either side the patella, and one an inch beyond each of these, and got the limb into a straight position. On recovering from the chloroform the child expressed no sense of pain, but sat up, and began to play with toys and other children in the ward.

"On the third day the skin between the cauterised lines looked red and inflamed. On the fifth, some separation at the edge of the slough had occurred. The horny portion gradually separated, and on the 1st January, 1860, the lines left were simply clear lines of ulcer, which were dressed with zinc ointment, discharged very little, and gradually healed. The knee was much diminished in size; moreover, it could be pressed without producing symptoms of pain. It was, however, still swollen, and on the 23rd January, when the scar was quite sufficiently healed, the knee was tightly strapped, and a roller applied from the foot.

"30th.—Strapping applied again, and towards the end of the week the child was dressed, and allowed to get about by aid of the sides of the bed and of a chair.

"March 6th.—The child is able to get about so well that the mother insists on taking her out; promises to bring her to me amongst my out-patients. This she has hitherto not done.

"Other cases showing the value of pressure might easily be given. I recorded three in the 'Lancet' for Dec. 20th, 1859. Several others proving the extreme value of this combination have occurred to me.

"We now, however, come to a much-neglected question—one which is, perhaps, scarcely comprehended in regard to the treatment of strumous synovitis—viz., is the principle of perfect rest to be exchanged for that of limited motion at any period of the disease? If so, at what period? I say that this question is either not understood or is ignored in England altogether; while, in Lyons, M. Bonnet applied some practical suggestions to the answer.

"I must, at the risk even of occupying much space, explain the principles whereon the value of passive motion, shampooing, &c., is based. When the cells, which have formed so abundantly in and around the synovial membrane, cease their generative activity, they remain for an indefinite period more or less passive. We know that the gelatinous condition thus produced may last for years without change, and that, being left undisturbed, the mass will, after a time, become the seat of abscess, cause destruction in surrounding parts, produce caries, &c.; or, in more favourable cases, it will begin to assume a fibroid character, and ultimately unite the two bones by anchylosis. Now, I have no hesitation in saying that, in the large majority of instances, the passive condition may be taken advantage of to induce a much more perfect, frequently an almost complete, cure of the malady; and that, by allowing it to continue, a much larger mass of disease is formed, much more tissue (periarticular, cartilaginous, or osseous) is implicated, and, therefore, even if the joint ultimately heal over, the cure is far from being as perfect as it might be made; and if degeneration set in, the ravages are unnecessarily wide-spread. Moreover, be it remembered, that if even a healthy joint be kept very long immovable, fatty degeneration of the cartilages is apt to come on, and even a sluggish inflammation of the synovial membrane. It must not be, however, for one moment imagined that I would advocate movement of the joint at all stages of the disease. On the contrary, such treatment can only be beneficial during the above-named passive condition, and when all inflammatory signs have disappeared. Hence it is important to form a correct judgment as to this condition. It is well known that each joint, when inflamed, presents a certain spot in which pain and tenderness are much more marked than elsewhere; this is in every joint a fixed point—on the hip, behind the great trochanter; in the knee, the edge of the inner condyle, inside the ligamentum patellæ; in the elbow, at the back, over the head of the radius, and so on. Now, if the surgeon find that pressure upon these points produces no pain, he may begin to move the limb with perfect confidence and safety; and, as far as my experience goes in this treatment (already pretty considerable), with very great benefit. The movement must not, at the beginning, be violent or long continued; a slight passive motion, and that rigidly in the normal direction—a certain amount of rubbing and kneading with the hand, and then reapplication of the splint, are all that can be undertaken; and it may be a long time before it will be safe to

abandon the patient's limb to his own management. I have also found it a useful plan, when it can be managed, slightly to change the angle of the splint at each reapplication.

"The subject of angle at which the joint would be flexed, would naturally lead us to consider another subject—viz., the value, as an actual remedy for inflammation, of changing any vicious position in which the joint may lie. There is no room for doubting the diminution of the inflammation and of the pain after this has been done; and amongst my cases are one or two which were clearly benefited by this means. But this subject is too wide, and space too limited, for its discussion here.

"The three methods more particularly named in this communication—viz., actual cautery, pressure, and passive motion—are neither original nor new; but the first and last more particularly are not used so frequently, nor with such discrimination and power, as they might be. Much benefit would result from substituting these means for the negative, if not injurious, treatment to which these strumous cases are too often subject."

The 'Dublin Medical Press' contains the following Case of *Congenital Malformation*, reported by Dr Joseph Edmundson of Carrick-on-Suir:

On the 26th of March, at eight p.m., I received an urgent ticket to visit Ally English, residing in Droleen's lane. The messenger seemed greatly alarmed, and stated that the child was born, but that they could not remove it from the mother. I hastened to the house.

"The patient, aged about thirty-five, a fine strong healthy woman, was the mother of five children, and her confinements had always been of short duration, favourable, and presenting no unusual feature. Her labour commenced at four p.m., the liquor amnii was discharged at six p.m., so that on my arrival she had been ill only four hours. The child was lying on the bed, with the exception of one leg which was retained in the vagina. I went to remove the child, not anticipating any difficulty, but found it firmly fixed; the leg was flexed on the thigh, and lying transversely in the vagina. I hooked my finger at the back of the knee, and had no difficulty in bringing it down. On further examination, the nature of the case—so far as its being a monster—was quite apparent. A continuation from below the pelvis of what appeared to be the neck of a child occupied the vagina, and after further careful examination I was satisfied that a large elsatic mass occupied the pelvis and prevented the completion of the labour; in fact, it felt like a neck and head continued from the pelvis of the child. Uterine action continued regular and very forcible, but not effective. I would here remark that the child was born alive, but had ceased to live prior to my arrival. I now assisted the efforts of the uterus by using strong tractive force for some time, and partially drew the mass towards me; but each time that I allowed an interval of rest, it immediately and rapidly passed back to its former position. On examinining it when partially drawn down and held *in situ*, I was satisfied as to its yielding and elastic nature. For obvious reasons, I was anxious, if possible, to remove it without perforating, and determined to use strong extracting force. Having used the catheter, I exercised continuous and steadily-increased force for about twelve minutes, when suddenly the mass came away like a shot. The perineum was properly supported, and escaped injury. The placenta came away immediately, the uterus contracting firmly and well.

"The extracting force resorted to would not, under other circumstances, have been justifiable, either as regards the amount used or the length of time it was continued without interruption; but the absence of any constitutional effect, as indicated by the state of the pulse, the comparatively little inconvenience and trifling amount of pain experienced by the patient whilst operating, convinced me that there was no bone or hard unyielding substance which would by pressure inflict injury on the soft parts covering the pelvis, and encouraged me to persevere until I finally succeeded.

"The child was somewhat under the medium size, the head, body, and extremities being in due proportion and well formed. The action of the hip-joints was unnatural; the natural position of the lower extremities was, lying parallel to the body, the feet near the shoulder-joints. When drawn downwards and outwards, they moved freely until at right angles with the body, when a little force brought them to meet the tumour. There was no trace of the nates or anus. The hip-joints were very deep seated; the pelvis must have been very narrow. In tracing the vertebral column downwards with the finger, it gradually became more deep seated until you reached the fourth lumbar vertebra, when you could no longer trace it with the finger. The neck of the tumour sprung from the position which would have been occupied by a line drawn across the centre of the nates (supposing the lower extremities to be in their natural position). The anterior and posterior surface of the neck of the tumour, and its connection with the body of the infant, presented the same appearance, except that an imperfect female organ occupied a central position on the anterior aspect. The labiæ were perfect, as also the clitoris, meatus urinarius, and urethra. The vagina was absent. I passed a catheter into the bladder and drew off about thirty drops of clear colourless fluid. The neck of the tumour and its connection with the body looked like an imperfectly-formed neck and shoulders. It was thicker than the neck of the child and shorter, white and smooth, presenting nothing remarkable in appearance.

"The tumour was more elongated than the head, and, as near as I could calculate, about a sixth greater in circumference. The anterior surface was white, covered with ordinary integument, the posterior of a deep purple colour, traversed with large blue veins, perceptibly raised above the surface, the line of demarcation between the two surfaces being very abrupt, the white comprising the anterior and lateral portion, the purple the posterior. Along the latter the integument was torn longitudinally through its entire extent (evidently by the extracting force used); its torn or ruptured surface was bleeding freely, and exposed to view nothing more than condensed cellular tissue. On the right side of the tumour was fixed an elevated mass about one inch by two in length, in colour darker than the surrounding skin, felt like a glandular mass.

"I was allowed to make an incision into the tumour, and as the poor woman occupied only one room, the remainder of the house being let to other families, I was compelled to examine it in her presence, and in fact on a portion of the straw upon which she lay. I divided it freely through its entire length, and about half its depth. It was composed of condensed cellular tissue. The incision opened into a cavity about two and a half inches long and one in depth, at its centre narrowed and rounded, at its extremities lined with cartilage, and containing a solid mass occupying about three-fourths of the cavity and floating in a teaspoonful of colourless serum; its surface was uneven and undulating, covered with a thin membrane, freely supplied on its surface with small red vessels. When cut into, it looked like white cerebral matter, but of much greater density.

"I have no doubt, from the peculiar elastic feel communicated on using alternate pressure with the finger, that the tumour contained other cavities of a similar nature. I regret much I had not an opportunity of making a full examination, as it was a subject of very great interest; but from the very great objection the humbler classes have to post-mortem examinations, it is impossible to get them to submit, no matter what amount of interest you may take in the case."

University of London.—The Senate of the University of London have just made a regulation to the effect that at the second examination for M.B., "the candidate who shall distinguish himself the most in Midwifery shall receive an exhibition of 30*l.* a year for the next two years, with the style of 'University Scholar in Midwifery.'" This is important as regards the encouragement it gives to the study of this subject. Up to the present time scholarships have been given in Medicine and Surgery, but nothing of the kind in Midwifery. It is only due to Dr Graily Hewitt to state that he was the first to propose that the Senate should award prizes to those gentlemen who had distinguished themselves in the art and science of Midwifery.

REVIEWS.

On Obscure Diseases of the Brain and Disorders of the Mind, &c. By Forbes Winslow, M.D., &c. London: John Churchill.

Perusal of this bulky volume has only served to convince us that the study of mental disease must make large advances before it can rise to the importance of a science. This, however, is not surprising when we consider the inherent difficulties of the subject. The mode of connection between mind and body; their mutual reaction; the conditions of healthy thought, as regards the cerebral organ; the obscure pathology of the latter; the absence of any recognised standard of sound mind;—these and many more conditions tend to surround the subject with perplexities that embarrass the most careful judgment. The acutest analyst finds himself entangled in a maze of doubt and wonder as he attempts to explain the phenomena presented to him, and to refer them to some definite laws. The study of simple abstract psychology—that is, the determination of the laws which govern the operations of the mind apart from its relations to matter, and the demonstration of the anatomy or pathology of the brain, independent of its psychical functions—are easy affairs in comparison with the analysis of the complex phenomena which are exhibited in cases of mental disease. Hence morbid psychological literature rarely takes a logical or inductive form; it is generally didactic and anecdotical, affording curious reading, if the term can be allowed with reference to subjects so painful, but rarely satisfying the understanding. The present work is no exception to this dictum; on the contrary, it is an exaggerated example of this style of literature. We are here presented with a multitude of cases, or more properly anecdotes, exhibiting many curious phases of mental derangement; but we look in vain for a satisfactory analysis of their phenomena, or the development of any leading principle or law around which we can group the incidents, or which can afford a starting-point for further inquiry. Too little philosophy and a wearisome amount of illustrations characterise the work. Dr Winslow has provided us with the *Mémoires pour servir;* but beyond that he has not aided the philosophy of his department. A great book is sometimes a great evil; and it is certainly too much the custom of modern authorship to run extensively into pica type and paper. All that is essential to the treatment of the subject could have been fully expressed in one-fourth the number of pages.

The object of the Author is to point out the indications of insanity in its incipient stages; an object of the highest importance, whether we regard lunacy from a philosophical or curative point of view. If we should ever construct a philosophical exposition of insanity, it will be by the observation of its phenomena in its earliest and doubtful stages, by tracing its gradual and insidious march as it steals almost unperceived over the domain of reason, and by noting down the successive steps by which the faculties of the mind have been thrown out of the sphere of healthy co-ordination. If, also, we would obtain the full effects of a judicious curative system, it must be by applying it at the onset of the disease. We recognise, therefore, the great importance of the task which Dr Winslow has undertaken.

Our Author informs us that the present treatise is only the introduction of two other volumes treating of more advanced forms of disease which he intends to publish: we must not, therefore, expect that completeness in the exposition of the topics which we should require in a perfect work. This treatise consists of twenty-five chapters, in which a large number of subjects are passed in review: for

example, the premonitory symptoms of insanity; anomalous and masked affections of the mind; the various stages of incipient insanity, as of consciousness, exaltation, depression, aberration, and mental impairment: then we have the morbid phenomena of attention and of memory, of speech, sensation, and the special senses; the morbid phenomena of sleep and dreaming, of organic and instinctive life, and the general principles of pathology, diagnosis, treatment, and prophylaxis, the chapter comprising which concludes the work. The introductory chapter is a fair specimen of the book, as the Author's peculiarities are represented in it in a marked manner. As an illustration of the danger of neglecting the earliest indications of cerebral disease, the Author cites numerous examples of individuals who have died suddenly and to the astonishment of their friends. The Author's specialty has led him to regard these cases of sudden death as due to cerebral disease: this is a very doubtful opinion, and in one of the instances he has recited we know it to be quite a wrong one. His last case is that "of a medical gentleman of known reputation" who retired to bed in his usual health, after playing a rubber of whist at a friend's house in the environs of London, and was found in the middle of the night in a state of apoplectic coma, and immediately after he expired. The writer of this review know this gentleman well: he appeared on a careless view to be in the possession of robust health, but on one occasion, when he was rallying the present writer on his sick looks, the respondent observing that his friend was breathing with some difficulty, somewhat abruptly placed a finger on his wrist, exclaiming, "Come, I think I am the better man now." To his surprise, the pulse intermitted to such a degree that it could scarcely be counted. He then seriously advised his friend to be careful of his health, and on his leaving the room predicted his speedy death, which took place a few weeks afterwards in the sudden manner already stated. This, then, was a case of disease of the heart, not of the brain—and of very old disease, too. Now this case, as reported by our Author, is a very telling anecdote; but it is of no value as illustrative of disease of the brain. It is the want of close examination and rigid analysis that deprives Dr Winslow's treatise of a scientific character. We quite agree with the Author in the following remarks:

"If the mental and cerebral condition of those who have been represented to have died of organic disease of the brain, apparently in full possession of their intellectual, sensorial, and motorial powers, had been subjected to a close and rigid analysis, some degree of disorder or impairment of these functions would, I believe, in many cases have been detected. We are too much disposed to form hasty generalizations in these cases, and to infer, that because the patient talks rationally for a time, on ordinary subjects, is under the influence of no appreciable illusion, hallucination, or aberration, that, therefore, the intellect is unclouded, and the brain in a perfectly sound and normal state. Such apparently healthy psychical and cerebral manifestations are quite consistent with the existence of encephalic disease, impairment, and even of actual latent and concealed mental aberration. These conditions of the brain and mind, would, I believe, be more frequently detected, if sufficient time were devoted to their analytical diagnostic tests, were scientifically employed by experts, practically acquainted with the art of examining the subtle phenomena of insanity."

Again he says:

"I affirm, that in every case of disease of the encephalon, particularly if the organic change or pressure be established in the vesicular matter, or in the membranes immediately investing the brain, a disordered or abnormal state of cerebro-psychical phenomena may, in the incipient stage, on careful examination, be detected."

The Author then considers the four forms into which he has divided the phenomena of unhealthy intelligence:—1. Exaltation; 2. Depression; 3. Alienation; 4. Impairment. Preliminary to the exposition of these special topics, the Author starts a series of interrogatories with reference to insanity, its nature, conditions, relations, &c. &c., which, however, are unanswered. He then discourses on the humane labours of Pinel, and awards to Dr Conolly the merit of abolishing the "severer forms of mechanical restraint"—a merit which does not belong to Dr Conolly, but to Dr Gardiner Hill, who originated and practised the method at Lincoln for some years before it was tried at Hanwell. Dr Conolly, in fact, visited Lincoln to examine its operation and ascertain its success before he adopted it in the large Metropolitan Asylum—another evidence of the cursory manner in which particular topics are handled by Dr Winslow. It is quite time that this, the greatest improvement in the treatment of the insane which modern genius has devised, should be accredited to its true author. 'The fact is, Dr Gardiner Hill must write a big book. Amidst the ignorance and barbarous cruelty of the physicians and lawyers of the days of Brown and Burns in relation to insanity, it is gratifying to find that one great lawyer, Lord Erskine, was before his time in advocating a humane treatment of the insane.

"'I consider,' says this renowned judge, 'the various trusts with which I am invested, in a manner, as nothing when compared with the *sacred duty* of protecting those who are visited with mania; it is as much a disease as any other with which it pleases God to afflict mankind, and I am sure it is always exasperated in its symptoms, and frequently rendered incurable by *unkind* and *rigorous* treatment.'"

Long recitals of the cases of persons who have recovered from lunacy, written by themselves, or autobiographies of the insane, then follow. One of these, headed "Confessions of a Patient after Recovery," occupies not less than fifty-eight pages, and the various histories altogether one hundred and eleven pages—rather an extravagant amount of space to devote in a professedly scientific book to narratives from which nothing is deduced. The style of some of these rhapsodies by no means attests the recovery of the patients.

Some judicious observations occur in the course of the chapter on "Local and Unrecognised Insanity."

"I presume it to be a generally-admitted axiom that the mind may be *disordered* without being *insane*, using this phrase in its strictly legal acceptation. These conditions of morbid intellect may be considered by some as only degrees of *insanity;* but I would suggest that this term be restricted to those mental disorders, accompanied with positive loss of control, clearly justifying the exercise of moral restraint, and to those morbid conditions of the intellect which sanction an appeal to the protective influence of the law. In other words, I would confine my remarks to those cases in which the mind may be said to be *pathologically* disordered, but not invariably *legally* insane.

"Have we in practice sufficiently appreciated this distinction? Fearful of committing ourselves to an opinion that might authorize an interference with the free agency of the patient, and justify the use of legal restraint, there has existed an indisposition to admit the presence of positive mental disorder, even in cases where it has been obviously and painfully apparent? This excessive caution—originating in motives that do honour to human nature—has often, I fear, been productive of serious, fatal, and irremediable mischief.

"The subject under consideration is one, I readily admit, of extreme delicacy, but, nevertheless, of incalculable importance to all sections of the community. It is, I admit, beset with difficulties and surrounded by dangers. In the hands of the inexperienced, the ignorant, indiscreet, and the wilfully designing, the facts that I have to record, and principles which I am about to enunciate, might be productive of much mischief; but, I ask, ought any apprehensions of this nature to deter the philosopher from entering upon so important an inquiry?

"The subject of latent and unrecognised morbid mind is yet in its infancy. It may be said to occupy, at present, untrodden and almost untouched ground. What a vast field is here presented to the truth-seeking observer, who, to a practical knowledge of human nature, adds an acquaintance with the higher departments of mental and morbid philosophy, as well as of cerebral pathology! How much of the bitterness, misery, and wretchedness so often witnessed in the bosom of families arises from concealed and undetected mental alienation! How often do we witness ruin, beggary, disgrace, and death result from such unrecognised morbid mental conditions! It is the canker-worm gnawing at the vitals, and undermining the happiness of many a domestic hearth. Can nothing be done to arrest the fearful progress of this moral avalanche, or arrest the course of the rapid current that is hurling so many to ruin and destruction?"

Here, in fact, lies the most important vocation of the philosophical alienist: it is here that he will find the greatest difficulty in the faithful discharge of his duty, yet nowhere is he required to exercise more judgment or courage. The extent to which insanity in a subtle and evasive form prevails in domestic life is hardly conceivable by persons unfamiliar with the subject: eighty per cent., we are told, of cases of insanity are curable if treated early, but if left late are doomed to irremediable mental darkness. This is a melancholy statement, yet true as sad.

We cannot follow out our Author through all the divisions of his subject; but we must not omit to express our pleasure with the graceful style in which he conveys his thoughts in some of the chapters admitting of sentimental and artistic composition. The chapters on Memory are pleasingly written, and will repay the perusal of the reader. To Dr Winslow belongs the credit of having made Pysehology an agreeable and popular study.

Medical Law in Tasmania.—The Legislative Council of Van Diemen's Land some time since passed an Act for the protection of the public and the Medical Profession. The third section of the Act is as follows:—"And be it enacted, that from and after the passing of this Act, no person shall do or perform, for fee or reward, or in expectation of receiving a fee or reward, any of the acts following—that is to say, practise as a physician, surgeon or apothecary, or prescribe to be taken or administer any medicine, or do or perform any surgical act or operation, unless some person shall have received from the president, or some member of the Court of Examiners to be appointed under the authority of this Act, a certificate, under the hand of such president or member, that it has been proved to his satisfaction that such person is a Doctor of Medicine of some university, or that he is a physician, surgeon, or apothecary licensed or admitted as such by some college of physicians or surgeons, or by the Society of Apothecaries of London or Dublin, or unless such person shall have obtained, after an examination publicly held before such Court of Examiners, letters testimonial of such Court to practise as a physician, surgeon, or apothecary, upon pain of forfeiting, for every such offence, a penalty or sum not exceeding 100*l.*" This properly stringent measure has been lately carried out by the mayor and other magistrates of Launceston. The offender was a Mr Clarke, who for some years past has been practising as a physician without complying with the provisions of the statute. In this instance, the information was laid for the recovery of the full penalty. It appeared in evidence that Clarke had attended on a child, and prescribed for it on two occasions. He had taken a fee of 5*s.*; and when the child appeared to be in danger, refused any further assistance. The Court, after taking into consideration all the circumstances of the case, had arrived at the conclusion that it was their duty to carry into effect the simple, strict, and, perhaps, severe aspect of the law, and ordered the defendant to pay a fine of 100*l.*, and 13*s.* 6*d.* costs. Mr Clarke was allowed twenty-four hours to pay the money into Court.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, JULY 4, 1860.

THE MEDICAL COUNCIL.

Our life is made up of illusions and disappointments. The beginning of undertakings is usually full of promise, and allures the fancy with brilliant anticipations of future prosperity and happiness. The covetous man will advance his gold, and the cautious man his character, on the probabilities of the venture. The mind delights in the gay colouring with which the imagination adorns every untried scheme; dissatisfied with the present, it fondly hopes that the future has something better in store, and that a compensation awaits it for all past mischances. Novelty is a great feeder of hope, for in the absence of experience there is no limit to the speculations of desire. The young man enters life with a persuasion that the world lies at his feet, and that all he need do is to walk in and take possession. Failure is impossible; and if he be a young Surgeon, his humblest expectation is that he shall keep his carriage before he have been ten years in practice. He knows the way to do it; and the geography of success is mapped out even to its shallowest soundings in his lively imagination. We do not blame him; for it is possible that if he were not inspired by these sanguine hopes, he would never find the heart to begin at all. Age, too, though boastful of its prudence, is almost as easily duped by the world's many-coloured bait. It is a delusion to suppose that credulity is the characteristic weakness of youth, and that wisdom abides with the aged alone. The bait must be adapted to the passion; and however suspicious a man may be, it is scarcely possible that his heart should be so worn out that there should be no room in it for a new delusion. Find his weak point, and the aged man will be led as easily into trouble as the young one who has no experience to protect him against rogues. The follies of age are notoriously very foolish. We cannot rail at each other; we are all prone to believe the best of every new thing according as it jumps with our whim, or is suited to our desire.

Our Medical Council was a new thing once; and how grand it seemed in its vast outline; how brilliant its future prospects! Its birth was celebrated with pæans and prophecies; Medical Editors who had done nothing to aid its gestation, endeavoured to out-chaunt each other to honour its nativity, and anathemas were ready for any unfortunate wight who spoiled the harmony by introducing a hoarse note of doubt or disapprobation. At last the Profession had obtained what it wanted—a grand governing Council that would equalise the standard of Medical Education, and put down quacks—or, at least, that might, should, would, or could do it; and therefore let us throw aside controversy, rub our hands, and be happy. Does anybody demur to these eloquent eulogiums, and, perplexed between his love of Medical Reform and his ducats, cry, "Give me back my two pounds!"—he is answered, "Wait awhile; let the Council get to work, and you will see that it will become the palladium of Medical rights, the great representative Parliament of the Profession!"

Many wise and sober men had faith that the Medical Council would have an honourable and useful career, and some of them assisted to establish and work it with a praiseworthy zeal. It is gratifying to know that the first men in the Profession were registered on the Council, and committed their reputation to the success of the experiment. Besides the men of *ex-officio* dignity, Sir Benjamin Brodie as the representative of Surgery, Dr Watson of Physic, and Sir James Clark of Courtly favour, lent it the influence of their names and experience. This fine ship was launched under the noblest auspices; the breath of popular approval filled its sails; it was manned with a chosen crew, and men of dignity and experience stood at the wheel; and yet, with all these advantages, it will not work: leaky at every timber, it will not answer the helm, and is now in so much trouble that several of the best men of the crew have already abandoned it to its fate.

Dr Watson has resigned; so also has Sir Benjamin Brodie, the President; and Sir James Clark anticipates a similar step.

What is this but a confession of failure—a desertion of a post that cannot be held with honour or profit? The Medical Council, in short, has failed—failed sooner even than we thought it would—but failed from causes that we have always predicted would be its ruin. The Council, in fact, has no functions; it is a huge machinery with nothing to do; for it is absurd to imagine that the annual compilation of a Register is an adequate duty for such a Council. It has no power to restrain quackery; it legalises Homœopathy, Hydropathy, and other eccentricities; it, or rather the Act it administers, has increased the evil of multifarious qualifications; it has no power to insist upon an equality of qualification, and such power as it does possess of regulating the curriculum is neutralised by the nature of its own constitution; it has unavoidably helped to exasperate the lamentable divisions that have made our Profession the reproach of society, and it is now brought to a dead-lock, and is placed in a slough of difficulties from which it can never be extricated.

It is idle to expect an important body, such as this pretends to be, to continue in operation without being endowed with duties corresponding to its authority and dignity. If the Medical Council cannot dominate the several Colleges, they will overrule it, and bring it into practical nullity and contempt. To this point it has, in fact, descended, and the gentlemen we have named, thoughtful for their reputation, have quitted their posts before the final crash may make it difficult to retire with honour.

Had the General Practitioners been more liberally recognised in the constitution of the Council, and larger powers given to it, its usefulness would have been greater and its career more honourable. We have on numerous occasions pointed out the defects of the Medical Bill as the certain causes of its ultimate failure; but we are not yet so aged as not to hope that the future has richer blessings in store than legislation has yet bestowed upon our Profession. Should this, too, prove a delusion, it will be pleasing, at least, to die in the hope.

SUMMARY OF THE WEEK.

REFORM OF THE MEDICAL ACT?

The Medical Council delegated to a Committee the duty of considering what improvements could be introduced into the Medical Act, and that Committee has presented its Report. We have not had time to compare the suggestions in that Report with the clauses of the Bill, so that we are not in a condition to express our opinion upon them *seriatim*. We have seen enough, however, to justify us in setting the Profession on their guard against any attempted jugglery on the part of the Council for the promotion of corporate interests. There has been much idle talk about the Medical Council being the Parliament of the Profession; but we are mistaken if the General Practitioners prove willing to accept the legislation of a body which in no sense represents their interests. We observe that there is a suggestion for the amendment of the 40th or Title Clause of the Act, by the insertion of certain words after the word "Apothecary." Now, as the word "Apothecary" occurs twice in the course of the clause, we should very much like to be informed which of the two is to have tacked on to it the new restriction. If the first, the clause will not be much strengthened, and the position of Registered Practitioners will be left as at present; if the second, there will be a new prohibition against *Registered* Practitioners calling themselves by any title under which they are not registered. It might have the effect of sanctioning a meditated alteration of the Charter

of the Royal College of Physicians, to the effect that a person may become a Licentiate in the College of Physicians without being able to call himself a Physician—a gross absurdity in terms, yet, nevertheless, a favourite notion among certain would-be reformers. We believe that Parliament would never suffer such bigoted legislation; and we believe, further, should it foolishly do so, the judges would find a reading of the clause which would negative the nonsense. At any rate, the Members of the Profession who are interested should begin to move; for they must not expect to find any sympathy in the Medical Council. There must be a reorganization of that body on truly representative principles, or its dissolution. Further legislation will inevitably lead to one issue or the other, if the Profession put on a bold front.

THE COLLEGE OF SURGEONS BEFORE THE MEDICAL COUNCIL.

Every Londoner—and almost every Member of the Profession has been a Londoner for three sessions—has seen announcements of a certain Society, where a round-faced lardaceous-looking layman dons a wig, and styles himself for the nonce Judge of the Court, and a certain number of other lean-looking characters are content to be boxed up and to officiate as Jurymen during the hearing of the sham causes that occupy the attention of the learned assembly. The forms of our Courts of Law are said to be ingeniously travestied in this Society, and a liberal amount of eloquent indignation is dissipated in irreverent jokes and peals of laughter. As we have no pleasure in these fooleries, even in fun, we cannot feel anything but pain when a really dignified assembly solemnly performs a similar farce on an occasion when it is called to sit in judgment on questions of vital importance to those whose interests are pleaded before it. The Medical Council has just suffered itself to be placed in this position. A very large number of memorials was addressed to the Council, protesting against the misconduct of the Council of the College of Surgeons in granting the Diploma to professionally-uneducated persons, and in obtaining a Charter enabling them to grant a special Diploma to Dentists. The Minutes of the Council do not say that those memorials were read; in all probability they were not, but contemptuously shuffled into a heap upon the table, or collected in a waste-basket: we are informed, however, that Mr Green made a statement that no unqualified persons had been admitted since the 1st of March, and that the practice would not be resumed; whereupon "the Council did not think it necessary to move in the matter." Discreet Council! How ardently their bosoms burn for the honour of the Profession! As for the Surgeon-Dentist question, the Council finds that "it has no authority to interfere," and so ends this serio-comic performance.

ALLEGED DANGERS OF VACCINATION.

It is well known that Mr Duncombe, the Member for Finsbury, is an enemy to vaccination, and has on several occasions in the House of Commons opposed legislation for its extension. He was one of Dr Michell's warmest supporters when that gentleman had a seat in Parliament. True to his antecedents, the eccentric Finsbury vaccinophobist has moved for a "return of the names and age of every non-commissioned officer and private vaccinated in the Shorncliffe Camp during the months of February, March, and April last; the names of those who have since died; the conditions exhibited in the arms of those who died; together with the number of amputations adopted to save the life of those affected with vaccination."

This most extraordinary motion must surprise any one into a smile who knows anything of the practice of vaccination; but among the public, who are ready to believe any absurdity, such allegations as are broadly implied in this motion are likely to excite the deepest alarm. Let us know what the motion means, without delay. Does it indicate facts, or is it merely the result of a nightmare which has haunted the imagination of the honourable Member until he has persuaded himself that it has a veritable existence?

LECTURES FOR LADIES.

The Ladies' National Sanitary Association has made arrangements for a Course of Lectures at the South Kensington Museum on sanitary subjects especially interesting to ladies. The Rev. John Armistead will open the Course with a Lecture on "Industrial Employments in Girls' Schools;" Dr Lankester will follow on "Sanitary Defects" generally; Mr Roberts, the architect, will expatiate on "Healthy Dwellings;" and Mr Ernest Hart, "Sanitary Commissioner of the 'Lancet'"—[Gracious powers! is Dr Hassall dead, or only suspended? or do the writers in the 'Lancet' decorate themselves with this title when they appear before the public, as the magnifico in a pantomime dresses himself in the gay clothes which his predecessor hung upon the pegs of the wardrobe?]—well, Mr Ernest Hart will lecture appropriately on "Dress and Social Habits"—social habits meaning, we presume, riding-habits, crinoline, and knickerbockers! By the way, have the ladies yet come to knickerbockers? Perhaps Mr Hart will be able to inform us. Let us not be mistaken, however; we think that courses of lectures, well selected, and not imbued with puff and pretence, will do much good in spreading useful information on sanitary subjects.

THE WATERLOO LIFE ASSURANCE COMPANY.

Mr Bermingham, the Medical Officer of this Company, has recently brought it into a Court of Law upon a point of great interest to Medical men, and, we are glad to say, has won his cause. In his capacity of Medical Officer to the Company, Mr Bermingham had examined a man who had suffered from delirium tremens, but who, at the time of examination, had recovered, showing no signs of the effects of his dissipation, and concealing the fact of his previous intemperance. The Company sustained an action at the man's death, and put their Surgeons into the witness-box, notwithstanding Mr Bermingham had informed them that his evidence would go against them. They were then dissatisfied with his testimony, and eventually deprived him of his appointment, on the plea of his having failed to protect the Company by want of skill. Mr Bermingham thereupon brought an action for damages. Evidence was given to prove that a man might recover from a first attack of delirium tremens, and show no trace of it a few days afterwards; and Mr Bermingham recovered damages to the amount of £200. This was a proper termination of the cause.

THE BRITISH ASSOCIATION AT OXFORD.

(From a Correspondent.)

As there has been a kind of adjournment "en bloc" of the London Medical and Scientific Societies this week to Oxford, it may be of more or less interest to the readers of the MEDICAL CIRCULAR to furnish a few notes of what has been going on here. We will pass over the conversaziones without end, tea-parties, lectures, plentiful as blackberries; we will pass by the eager sight-seers in the park in dozens descanting on the new Museum and Professor Owen's jaw-breaking big names and homologies. The Oxford rifle band, too, we must neglect in another Deucalion deluge, striving to make things agreeable out of doors, but succeeding very imperfectly.

It is not at all in our line to describe the *gaudeamus* to-day in the "Sheldonian," or the degree of D.C.L. conferred on M. de la Rive, Lord Rosse, Professor Sedgewick, or the President: we took, therefore, an *insouciant* ramble into the Bodleian, to see its wilderness of books, and to see our old friend, Mr Bulkeley Bandinell, and our favourite picture, Lord Burleigh riding on his mule. The former rev. gentleman is the Mr Chatto of the libraries here—quite as stern, and never, by the way, or at all, over-polite, though these are the two best librarians the present writer has ever met. It may be said, too, we do not speak out of book, for we happen to know a good many of the nooks and crevices of both libraries, and the Radcliffe to boot. It is gratifying to find the new Museum so fine also, and that in the corbels of the piers of the new walls—with Galileo, Leibnitz, and Newton, given by H.R.H. the Prince of Wales; Davy and Watt, by the University—Mr Ruskin, with exquisite taste, in compliment to Dr Acland, has set up a statue of Hippocrates! Any old Oxford man need scarcely be reminded of the marble zany with cap and bells which represents the "Faculty of Medicine" in Dr Daubeny's College, Magdalen, and a somewhat similar legend painted on the walls of the "Sheldonian." All honour, therefore, to Mr Ruskin, who, though we have still representatives of the antique as at Magdalen in London, (*a*) has preferred the sage Hippocrates to the absurd figure at Magdalen.

(*a*) Men as antique sub-editors, who help to demoralise or break the heart of struggling honest but poor young medical men in this year of 1860, but write biographies of Heenan and Sayers to sell their journals; or the antique, not honest, advocates of cheap Dentists' Diplomas or other Diplomas at the College of Surgeons, for the same not very dignified commercial purpose of bringing back Barber Surgeons and cheap diplomas, the Figaros and Sangrados of a time we thought long gone by.

It is not one's purpose to say much of the other "Sections," such as the Mathematical or Physical, where the condition of the sun has been much discussed, with sundry grave ideas put forth of masses of ice in the Arctic Seas not yet melted as the cause of the present dismal summer; nor are we given to discourses on the stars: so, when not engaged in the Physiological Section, *absit omen*, we have engaged a horse for a gallop in St Giles's, if not half the road to Banbury, taking care to procure notes of the Physiological Section.

Some amusement was caused one day last week, as nobody could find the "Chemical Section." Like their own phlogiston, some of the gold-tasseled swells said chemists had gone away into the realms of unreality! Mauve-coloured dyes from aniline had been explained a few hours before, to the great delight of the gentler sex. What if the philosophers and ladies had gone off together? But, phew! bless my soul! when one remembers the fact and the discovery! The "Section" were, it turned out, busy underground trying experiments in deodorising sewage in an atmosphere of rotten eggs! For chloride of iron, as held by Dr Frankland, was being explained as the most useful of the deodorisers; the much-vaunted Leister plan by lime and chloride of lime, as tried at the east end of London, at Hackney, having proved a failure. In the debate of the chemists there seemed no difficulty as to deodorising solid animal dejecta, the fluid portion of the sewage being the insuperable impossibility that none of the Lethebys, Millers, Franklands, Spencers, or Mechis could surmount; and so it rests at present.

Oxford, it need scarcely be said, is replete with interest in the history of our Profession. In the physiological department, Mr Chadwick read a paper espousing views like those of Mr Hilton—that in our public schools there is too much mental wear and tear of brain required of children. The evidence of all the best Government overseers of schools and school-masters tends to show that the voluntary attention of children in schools cannot be sustained more than two hours in the morning and an hour in the afternoon, and rest is much called for. In an uncomfortable long address by the President, Lord Wrottesley, a set of facts at second-hand as to medicine were referred to, and in aristocratic mode blandly patronised as the latest advances in physiology; such as "chemical history of nutrition," probably referring to the functions of the pancreas recently made out; then the "dynamics of the blood," whatever that may be; next, the investigation of the phenomena of the senses, and electricity of nerves and muscles, with a touch of the old fudge about the path opened by Newton and Bacon in the physical investigation of phenomena, not physical at all; things of which Virchow, Kolliker, Brown-Séquard and Bain tell us rather more a million times than Newton. The antiquity of the human race, as shown by the celebrated flint implements in the valley of the Somme, was also referred to, but not any further light thrown on the subject.

The present meeting of the British Association, though of vast importance to the individuals collected at Oxford, has not excited that attention, especially in physiological matters or the medical world, that one might have expected: if we had a "Section" to discuss—such popular trifles as Netley Hospital, Whitworth cannons, or some plan of infallible rifle-shooting, or Dr Farr's statistics, or some patent algebraic mode of horse-taming or bull-fighting—then, indeed, we might expect each of the Medical Journals to send a horse-riding reporter. Meeting an Italian physician, the chief practitioners in Rome recently asked him, in an inverse order of the simple rustics in Virgil's Eclogue, what wonderful thing had most attracted him from Rome? He said, with simple but extraordinary enthusiasm, "The chief thing, Signor, was to see the school where Sydenham wrote his glorious classic works; to see where Harvey completed the figure of 8 of the two circulations; to see Oxford." We could not help saying "*Quantum mutatis!*" Yet there is a *religio loci* still to any one who knows Oxford, and Sydenham's writings, and Harvey's life.

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, JUNE 19TH, 1860.

Royal College of Physicians, London.

Sir BENJAMIN C. BRODIE, Bart., President, took the chair, at two o'clock p.m.

Present—Dr Burrows, Mr Green, Mr Nussey, Dr Acland, Dr Bond, Dr Embleton, Dr Storrar, Dr Alexander Wood, Dr Andrew Wood, Mr Watt, Mr Syme, Dr A. Thomson, Dr A. Smith, Dr Leet, Dr Apjohn, Dr Corrigan, Sir James Clark, Sir Charles Hastings, Mr Lawrence, Mr Teale, Dr Christison, and Dr Stokes.—Dr Francis Hawkins, Registrar.

The minutes of the last meeting were read and confirmed.

The Solicitors of the Council being present—

Moved by Mr Teale, seconded by Dr Alexander Wood, and agreed to—"That it having been proved to the satisfaction of the General Council that the entry of the name of Richard Organ has been fraudulently and incorrectly made on the Register, the General Council do by this order, in writing, direct that his name be erased from the Register."

Moved by Mr Green, seconded by Mr Nussey, and agreed to—"That Richard Organ having been judged by this General Council after due inquiry, to have been guilty of infamous conduct in a professional respect, the General Council do hereby adjudge that the name of the said Richard Organ be erased from the Register, and do by this order direct the Registrar to erase his name from the Register accordingly."

Moved by Dr Storrar, seconded by Mr Syme, and agreed to—"That a copy of these orders, signed by the President in the Chair, and countersigned by the Registrar, be transmitted to Richard Organ."

The adjourned debate on the Dublin Apothecaries' question was resumed.

Dr Alexander Wood was allowed to withdraw the amendment which he had moved on the 16th of June—viz., "That it does not appear to the Medical Council, that the Act of the Apothecaries' Hall of Dublin confers on the Licentiates of that body any right to practise Medicine;—That, in the opinion of the Council, the inclusion of the title of Licentiates of that Body in Schedule (A) of the Medical Act does not confer any new powers on that Body;—That the Council therefore adhere to the opinion expressed by them on the 8th of August, 1859,"—in order that the amendment moved by Dr Corrigan on the 18th of June might be substituted for it,—viz., "That the General Medical Council having again carefully considered the subject referred to in the letter from the War Office, of 23rd March, 1860, addressed to the Secretary of the Apothecaries' Hall of Ireland, adhere to the opinion expressed by them in their Resolution of 9th August, 1859, which is as follows: 'That it is the opinion of this Council that the Licence of the Apothecaries' Hall of Ireland is not equivalent to a Degree or Licence in Medicine from a University or College authorised to grant such, as from a perusal of the Apothecaries' Act, 31 Geo. III., there does not appear to be any provision or authority for examining in Medicine: and further, that if a Candidate be rejected by the Apothecaries' Hall of Ireland, the Apothecaries' Act, Sec. 23, declares that the rejected Candidate may appeal to the King and Queen's College of Physicians in Ireland, who are then authorised to reverse such decision, if it seem fit to them, and to grant to such appellant the right to practise the Art and Mystery of an Apothecary without any examination in Medicine.'"

The amendment moved by Dr Corrigan, and seconded by Dr Stokes, was put to the vote, and carried.

Dr Storrar required that the names of the Majority and Minority should be entered on the Minutes.

Majority: Mr Green, Dr Acland, Dr Bond, Dr Alexander Wood, Dr Andrew Wood, Mr Watt, Dr A Smith, Dr Apjohn, Dr Corrigan, Mr Lawrence, Mr Teale, and Dr Stokes.

Minority: The President, Dr Burrows, Mr Nussey, Dr Embleton, Dr Storrar, Mr Syme, Dr A. Thomson, Dr Leet, Sir James Clark, Bart., Sir Charles Hastings, and Dr Christison.

Moved by Dr Andrew Wood, and seconded by Dr Christison—"That the Letter from Dr James Murray Macculloch, and the Opinion of Counsel on his case, be recorded on the Minutes."

Amendment moved by Dr Corrigan, and seconded by Dr A. Smith—"That the Letter from Dr Macculloch be inserted in the Minutes."

Amendment carried.

"38, Castle street, Dumfries,
"May 29th, 1860.

"SIR,—Although personally a stranger to you, I take the liberty of writing to you upon a matter personal to myself. I have observed from a notice, published in the 'Edinburgh Medical Journal' for December 1859, that it has been proposed to call the attention of the Medical Council, of which you are President, to my connection with the case of Mr Broatch, who was convicted under the Medical Act in September last year.

"I am anxious that my conduct should not be misunderstood; and as I am not aware whether the Council may think it right to take any official cognizance of the matter, I beg to solicit your impartial perusal of the facts, in order that with you, as the head of my profession, I may not stand under undeserved imputation.

"I do not trouble you with any of the personal and acrimonious discussion which has taken place. It may suffice to say, that a great deal of enmity and ill feeling has been exhibited towards me, and I have no doubt I have myself been heated, and in some respects injudicious.

"The facts to which I beg your attention are these. The Medical Act, which fixed the date of its operations for the 1st of January, 1859, was not fully understood in the district of the county in which I resided (Dumfries). Indeed, the only advertisement on the subject (which appeared only once in one of the local papers of the district), informing Medical Practitioners of the necessity for Registration, was on the date of December 14, 1858, so that a very short time was given to comply with the provisions of the Act.

"As one of the conditions of the Registration, it was necessary to forward certain attestations of qualification, one of which was the signature of a Medical man to a certificate purporting to state that the claimant had exhibited for the inspection of the signer his Diploma or Qualification.

"Knowing the object of the Statute to be to prevent the operation of quacks and charlatans, under the cloak of professional titles, I regarded this as a mere matter of form with respect to Medical men on whose qualifications no reasonable doubt rested, and I have reason to know that it was so regarded by the majority of the Practitioners in this district.

"Mr Broatch was one of the Medical men of this district who did not hear of or see the advertisement of the 14th December, 1858, until nearly the entire interval had expired. He came to me a few days before the 1st of January, 1859, to sign his Certificate. I asked him for his Diploma, as the Certificate stated that I had seen it. He told me that he had passed and got his Diploma in March, 1822, from the Edinburgh Royal College of Surgeons; that in 1826, before leaving Edinburgh (where he first practised), he had brain fever, was long ill and insensible, and that when he recovered he found he had been robbed, his Diploma having disappeared with the other things. Shortly afterwards removing to Dunscore, he commenced practice again, and finding no special use for his Diploma, he had neglected to apply for a Duplicate or a Certificate.

"I fully believed Mr Broatch, and indeed, notwithstanding subsequent events, I still believe that he did not deceive me. I had known Mr Broatch for thirty years, having repeatedly met him in practice, and ever found him truthful, honourable, and skilful. I knew that he was met and respected by all the practitioners of the district of any standing. I knew he was respected

and bore a high character in his own locality. I knew he was and had been parochial Surgeon to two parishes for many years; an appointment not held by unqualified practitioners in this part of the country before the passing of the Medical Act. I had seen his name year after year in the 'London Medical Directory,' a work of general accuracy, as a Licentiate of the Edinburgh Royal College of Surgeons, 1822; and I knew, from personal experience, that his story was not improbable. I had myself lost one of my diplomas for a long time, and recovered it by the merest chance, and I had experienced the delay and difficulty arising out of an application for a Duplicate or Certificate, even when my application was supported by the powerful aid of my late friend Mr Liston. According to Mr Broatch's statement, it was simply impossible for him to comply with the letter of the requirement of the Certificate, and yet it appeared that in a few days he must either be registered or professionally outlawed. I did not see Mr Broatch's Diploma, but I firmly believed in his qualification; and as I regarded the Certificate as intended to supply what the Act calls 'Proper evidence that the person claiming Registration is entitled to it,' I signed it, professional outlawry being the result in a few days if I had not. I do not seek to justify myself for so doing. It was incautious, an act of the feelings unsanctioned by the judgment and the dictates of self-interest, and I am very willing and do express my regret. The circumstances you will be able to estimate as strongly as I can.

"I do not wish now to discuss the question of Mr Broatch's trial. I may only say, that so far from any desire on my part to defeat or assist in defeating the provisions of the Act, I immediately replied to the inquiries of the Registrar of the Scottish (Branch) Council, in perfect frankness, and had also to perform the painful duty of giving my evidence against Mr Broatch, without which, by the way, he could not have been convicted at all.

"Such are very briefly the facts of the matter referred to in the Minute published in the Edinburgh Journal.

"Of the publication of that Minute, in so far as it refers to me, I say nothing further than to remark that the Medical Act does not contemplate or authorise such a publication. The status and character of a Medical man should not be injured wantonly, and it certainly was not intended that *ex-parte* accusations should be circulated in the Public Journals under the shield of a Minute of the (Branch) Medical Council, more especially before the said Council, by their own showing, knew whether they were entitled to entertain the subject or not; but, as I said before, I do not wish to trouble you with personal grievances or discussion.

"I have been anxious to state to you the circumstances under which I acted; having committed an error, I have desired to express regret. I feel sure you will pardon my intrusion in such a matter, and beg leave to subscribe myself,

"Your most obedient Servant,

"JAMES MURRAY MCCULLOCH.

"To Sir BENJAMIN C. BRODIE, Bart.,
"14, Saville Row, London—W."

The following Resolution was unanimously adopted by the Council, on the motion of Mr Green, seconded by Dr Andrew Wood—"Having just learned that during this day's sitting, Dr Williams, the Representative of the Royal College of Surgeons of Ireland, has died; under the unprecedented and afflicting circumstances the Council record the unfeigned sorrow which they feel under the irreparable loss of a colleague so estimable and distinguished."

Confirmed—B. C. BRODIE.

MINUTES OF MEETING, JUNE 20TH, 1860.

Royal College of Physicians, London.

Sir BENJAMIN C. BRODIE, Bart., President, took the Chair, at three o'clock p.m.

Present—Mr Green, Mr Nussey, Dr Bond, Dr Embleton, Dr Storrar, Dr Alexander Wood, Dr Andrew Wood, Mr Watt, Mr Syme, Dr A. Thomson, Dr A. Smith, Dr Leet, Dr Apjohn, Dr Corrigan, Sir James Clark, Sir Charles Hastings, Mr Lawrence, Mr Teale, Dr Christison, and Dr Stokes. —Dr Francis Hawkins, Registrar.

The minutes of the last meeting were read and confirmed.

Moved by Dr Stokes, seconded by Sir Charles Hastings—"That the following letter be transmitted to the War Office:—

"General Medical Council, June 20, 1860.

"SIR,—In reference to your letter of June 4, 1860, I have the honour to transmit the enclosed resolution of the General Medical Council, passed at their meeting, June 19, 1860:

"'That the General Medical Council, having again carefully considered the subject referred to in the letter from the War Office, of March 23, 1860, addressed to the Secretary of the Apothecaries' Hall of Ireland, adhere to the opinion expressed by them in their resolution of August 9, 1859, which is as follows: That it is the opinion of this Council that the Licence of the Apothecaries' Hall of Ireland is not equivalent to a Degree or Licence in Medicine from a University or College authorised to grant such, as from a perusal of the Apothecaries' Act, 31 Geo. III, there does not appear to be any provision or authority for examining in Medicine: and further, that if a candidate be rejected by the Apothecaries' Hall of Ireland, the Apothecaries' Act, Sec. 23, declares that the rejected candidate may appeal to the King and Queen's College of Physicians in Ireland, who are then authorised to reverse such decision, if it seem fit to them, and to grant to such appellant the right to practise the art and mystery of an Apothecary without any examination in Medicine.'

"I am further directed by the General Medical Council to state that they would have been gratified to put their reply in more definite terms, but there appears to the Council to be considerable doubt as to whatare privileges or legal qualifications of the Apothecaries of Ireland, and the Council cannot therefore give any authoritative opinion in reference to the value of their Licence as a claim for admission to the competitive examination for the appointment of Assistant-Surgeon in the Army.

"I am, Sir,

"Your obedient Servant,

"FRANCIS HAWKINS, Registrar."

Amendment moved by Dr Storrar, seconded by Sir James Clark—"That the letter from Mr Secretary Herbert of June 4 be read again."—Amendment negatived, original motion carried.

Dr Andrew Wood required that the names of the majority and minority should be entered on the Minutes.

Majority: Mr Green, Dr Bond, Dr Alexander Wood, Dr Andrew Wood, Mr Watt, Dr A. Smith, Dr Apjohn, Dr Corrigan, Sir Charles Hastings, Mr Lawrence, Mr Teale, and Dr Stokes.

Minority: Mr Nussey, Dr Embleton, Dr Storrar, Mr Syme, Dr A. Thomson, Dr Leet, Sir James Clark, and Dr Christison.

A petition from Mr John Broatch, accompanied by testimonials, was read, praying that his name might be re-inserted in the 'Medical Register' "As a Surgeon in the Public Service."

Moved by Dr Andrew Wood, seconded by Dr Storrar—"That Mr John Broatch's petition to have his name restored to the 'Medical Register' be not complied with."—Agreed to.

Moved by Mr Syme, seconded by Dr Alexander Wood—"That the Medical Council having had their attention called to a practice prevailing in some of the English Medical Institutions, of requiring the London Apothecaries' Licence as an essential qualification, or paramount recommendation, for appointment to professional offices, resolve to record their opinion that this practice is neither consistent with the letter and spirit of the Medical Act, nor expedient for the interests of the public.

Amendment moved by Mr Nussey, seconded by Dr Leet—"The Medical Council having no power to interfere with the practice said to prevail in the English Medical Institutions with respect to the qualifications they may require for their Officers, such interference being wholly beyond their province, resolve that it is not desirable or expedient to entertain the motion of Mr Syme."—Amendment negatived, original motion carried.

Mr Nussey required that the names of the majority and minority should be entered on the Minutes.

Majority: Dr Alexander Wood, Dr Andrew Wood, Mr Watt, Mr Syme, Dr A. Smith, Dr Apjohn, Dr Corrigan, Sir Charles Hastings, Mr Teale, and Dr Stokes.

Minority: Mr Green, Mr Nussey, Dr Bond, Dr Embleton, Dr Storrar, Dr Leet, and Mr Lawrence.

Dr Alexander Wood read the following Draft of a Bill for the further Amendment of the Medical Act, promoted by the Colleges of Physicians of London and Edinburgh, and assented to by the King and Queen's College of Physicians in Ireland.

A BILL FOR THE FURTHER AMENDMENT OF THE MEDICAL ACT, 1858.

Whereas by "The Medical Act, 1858," it is provided that it shall be lawful for her Majesty to grant to the Corporation of the Royal College of Physicians of London a new charter, and thereby to give to such Corporation the name of "The Royal College of Physicians of England;" and to grant to the Corporation of the Royal College of Physicians of Edinburgh a new charter, and thereby to give to the said College of Physicians the name of "The Royal College of Physicians of Scotland;" and to grant to the Corporation of the King and Queen's College of Physicians in Iraland a new charter, and thereby to give to such Corporation the name of "The Royal College of Physicians of Ireland;" but provision is not made by the said Act for reserving to the said Colleges, and the Presidents, and Censors, Fellows, Members, Licentiates, and Extra-Licentiates thereof respectively, by their said new names, the powers, privileges, liberties, and immunities to which they are respectively entitled by their existing names: and doubts have arisen whether, in case of the acceptance by these Colleges respectively of new charters under such altered names respectively, the said powers, privileges, liberties, and immunities would legally attach and be preserved to them; and it is expedient that such doubts should be removed: And whereas by the 47th section of the said Medical Act, it is provided, that within twelve months after the granting of such new charter to the Royal College of Physicians of London, any Fellow, Member, or Licentiate of the Royal College of Physicians of Edinburgh, or of the Queen's College of Physicians of Ireland, who may be in practice as a Physician in any part of England, and who may be desirous of becoming a Member of such College of Physicians of England, shall be at liberty to do so, and be entitled to receive the diploma of the said College, and to be admitted to all the rights and privileges thereunto appertaining, on the payment of a registration fee of 2*l*. to the said College; and it is expedient that the said proviso should be repealed: And whereas by an Act passed in the 14th and 15th years of King Henry the Eighth, intituled "The Privileges and Authorities of Physicians in London," certain Letters Patent, dated the 23rd day of September, in the tenth year of the reign of his said Majesty, whereby certain Physicians in London therein named were incorporated by the name of "The President and College of Commonalty of the Faculty of Physic in London," were ratified and confirmed; and by the said Act it was enacted, that the six persons named in the said Letters Patent, and two more of the said Commonalty, to be chosen by them, should be called Elects, and that the said Elects should yearly choose one of them to be President of the said Commonalty, and that as oft as any of the places of the said Elects should become void, the survivors should choose and admit one or more, as need should require, of the said Faculty to supply the number of eight persons; and that no person should from thenceforth be suffered to practise in Physic through England until he be examined by the said President and three of the said Elects, and have from them Letters Testimonial, except he be a Graduate of Oxford or Cambridge: And whereas the main function of the said Elects, viz., that of examining and granting Letters Testimonial, has been virtually superseded by the said Medical Act, and they have ceased to grant Letters Testimonial in accordance with the provisions contained in the last-recited Act, and it is therefore expedient that the before-recited provisions should be repealed: Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

I. The expression in the Medical Act and this Act, "The Corporation of the Royal College of Physicians of London," or "The Royal College of Physicians of London," shall be taken to denote the Corporation of "The President and College or Commonalty of the Faculty of Physic in London."

II. Any new charter which, under the pro-

visions of the Medical Act, shall be granted to the Corporation of the Royal College of Physicians of London, may be granted to them either by and in the name of the Royal College of Physicians of London, or, as provided by that Act, by and in the name of the Royal College of Physicians of England; and any such new charter granted to the Corporation of the Royal College of Physicians of Edinburgh, may be granted to that College either by and in its present name, or, as provided by the Medical Act, by and in the name of the Royal College of Physicians of Scotland; and any such new Charter granted to the Corporation of the King and Queen's College of Physicians in Ireland, may be granted to that College either by and in its present name, or, as provided by the Medical Act, by and in the name of the Royal College of Physicians of Ireland.

III. The granting of new charters to the said Corporations respectively, by and in the altered names and styles respectively, as provided in the Medical Act, shall not, in respect of such alteration of name or style merely, alter or affect in any way the rights, powers, authorities, qualifications, liberties, exemptions, immunities, duties, and obligations granted, conferred, or imposed to or upon, or continued and preserved to the said Corporations respectively, and the respective Presidents, Censors, Fellows, Members, and Licentiates thereof by the respective Charters and Acts of Parliament relating to the said Corporations respectively, or by the Medical Act, the Act to amend the Medical Act, the Medical Acts Amendment Act 1860, and this Act respectively; but the said Corporations respectively, and the respective Presidents, Censors, Fellows, Members and Licentiates thereof, shall, notwithstanding any such change of name and style, have and retain all such and the same rights, powers, authorities, qualifications, liberties, exemptions, and immunities, and be subject to all such and the same duties and obligations, as if such new Charters respectively had been granted to them by and in their respective names and styles as then existing.

IV. Each of the said Corporations shall also, notwithstanding any such alteration of name or style, have, hold, and enjoy, and continue to have, hold, and enjoy, all lands and other real and personal heritable and moveable property belonging to such Corporation, either beneficially or in trust, at the date of the granting of such new charter, and may execute and perform any use or trust for the time being vested or reposed in such Corporation.

V. From and after the passing of this Act, the before recited provision of the Medical Act, which entitles any Fellow, Member, or Licentiate of the Royal College of Physicians of Edinburgh, or of the King and Queen's College of Physicians in Ireland, to receive the Diploma of the College of Physicians of England, and to be admitted to all the rights and privileges thereto appertaining, shall be, and the same is hereby, repealed.

VI. So much of the Act of the 14 and 15 Henry VIII., c. 5, as relates to the Elects of the said Royal College of Physicians of London, and their powers and functions, shall be, and the same is hereby repealed; but this repeal shall not prejudice or affect the rights and privileges of any persons to whom the said Presidents and Elects may have granted letters testimonial, and all trusts which, by any deed, gift, devise, or bequest are vested in, or to be executed or performed by the Elects, or some defined number of them, shall vest in and accrue to, and be executed and performed by, the Censors of the said College for the time being, as if the names of the Censors had in such instruments respectively been used instead of that of the Elects.

VII. The office of President of the "Royal College of Physicians of London" shall be an annual office; and Thomas Mayo, Doctor of Physic, the now President of the said Corporation, shall remain such President until the day next after Palm Sunday in the year 1861, when he shall go out of office, and the Fellows of the said Corporation shall, at a meeting to be holden by them for that purpose, on the same day, and on the same day in every subsequent year, elect some one of the Fellows of the said Corporation in such a manner as shall be provided by any bye-law or bye-laws made in that behalf by the said Corporation and for the time being in force, to be President of the said Corporation; but the retiring President shall always be capable of being re-elected, and every President shall remain in office until the actual election of a new President; or, in case of the death, resignation, or other avoidance of any such President before the expiration of his year of office, the said Fellows shall, at a meeting to be holden by them for that purpose, as soon as conveniently may be (of which due notice shall be given) elect one other of the Fellows of the said Corporation, in such manner as aforesaid, to be President for the remainder of the year in which such death, resignation, or other avoidance shall happen, and until such election the duties of President shall be performed by the Senior Censor for the the time being.

Moved by Dr Alexander Wood, seconded by Dr Storrar—That the Council approve of the Draft Bill now read.—Agreed to.

5. A communication from the Poor-law Board, in reference to qualifications for Poor-law Medical Appointments, was read.

Moved by Dr Andrew Wood, and seconded by Mr Lawrence—That the communication from the Poor-law Board be inserted in the Minutes.

Amendment moved by Dr Corrigan, and seconded by Dr Embleton—That the Registrar be directed to thank the Secretary of the Poor-law Board for their communication and circular.

Amendment carried.

6. Letters from a Medical Practitioner in Jamacia, and the following from the Colonial Office, were read:

"Downing street, March 30, 1860.

"Sir,—In answer to your letter of the 14th instant, stating the objection of a Scotch Medical Practitioner in Jamaica to an Island Act recently passed, to provide for registering duly-qualified Medical Practitioners, I am directed by the Duke of Newcastle to inform you, that although the provisions of the Jamaica Act may not be in themselves unreasonable, they are considered to be repugnant to the English statute, and therefore the Colonial Legislature will be called upon to amend them, before the Act can receive the Royal Assent.

"I return the copy of the Act which accompanied your letter.

"I have the honour to be, Sir,

"Your obedient servant,

"Sir B. Brodie, Bart." C. FORTESCUE."

Moved by Dr Andrew Wood, seconded by Dr A. Smith—That the foregoing letters, and the 13th and 20th Sections of the Jamaica Bill, be entered on the Minutes.—Agreed to.

7. Moved by Dr Christison, seconded by Dr Alexander Wood—That a Committee, consisting of Dr Christison, Dr Alexander Wood, and Dr Storrar, be appointed to extract from the Minutes of Council such regulations as have been passed by the Council for conducting the business of the Council, and to report such alterations and new regulations as may appear to the Committee to be advisable.—Agreed to.

Confirmed—CHARLES HASTINGS.

GENERAL CORRESPONDENCE.

THE KING & QUEEN'S COLLEGE OF PHYSICIANS *v.* APOTHECARIES' HALL, DUBLIN.

To the Editor of the Medical Circular.

SIR,—Your impression of the 13th contains a long letter with the above heading, from "A Dublin Practitioner, retired from Practice." Reasoning on the inconsistency of this signature, it has struck me that his letter, so far from strengthening the cause which he has espoused—the Apothecaries' Company—tends very much to weaken it. Thus, the "3rd George III., chap. 28, enacts that the minister, during his visitation of the jail prisoners, is empowered, in case of sickness, to employ a physician, apothecary, or surgeon, and to pay for such medicines prescribed." To this quotation it is only necessary to reply, that if the apothecary were to prescribe, there would be no need of the physician: or if the "Dublin Practitioner" will not consent to this view, he is bound to admit that the apothecary may also act as the surgeon.

The "Dublin Practitioner's" second quotation (17th & 18th George III., chap. 21) enacts the appointment of an experienced apothecary or surgeon, at a salary, to each jail or prison where malignant fever prevails.

The third, "26th George III., chap. 14, fixes the apothecary's salary for his attending," not for his prescribing for, "prisoners, and providing medicines."

The fourth, "58th George III., chap. 47, permits the apothecary, as well as the surgeon and physician, to admit, by means of certificate, infected persons into fever hospitals."

The fifth, "6th & 7th William IV., provides fees for apothecaries attending inquests as medical witnesses."

The sixth, "1st Victoria, chap. 27, renders valid an apothecary's certificate for placing lunatics under restraint."

The seventh, "6th & 7th Victoria, chap. 107," and "12th & 13th Victoria, chap. 33," enact that "no ship, &c. &c. &c., proceed on her voyage, unless there be on board some person authorised by law to practise in the United Kingdom as physician, apothecary, or surgeon."

I have thus quoted all the authorities cited by the "Dublin Practitioner." The first quotation has been already replied to; the second does not specify the nature of the apothecary's duty, and your correspondent *cannot assume* that he is to act the part of medical attendant.

The third makes use of the word "attending." Query, administering or providing medicines?

The fourth provides for the admission into fever hospitals of persons ill of fever, on the apothecary's certificate. This surely does not give him liberty to treat such cases?

The fifth, *a comparatively recent authority*, calls the apothecary giving evidence at an inquest "a medical witness." It remains with your correspondent to explain this term. I rather think that, unless the apothecary had a surgical or medical licence in addition, his evidence would not be relied on. In any case, the above term does not constitute him a physician or surgeon.

The sixth, *a still more recent authority*, legalises the apothecary's certificate in cases of lunacy; but supposing, for argument's sake, that there is any weight in this point, it must be remembered that there are very few apothecaries in Dublin at present who are without medical or surgical qualifications. Upon these latter depends the strength (!) of your correspondent, and not upon the licence of the Apothecaries' Hall.

The seventh, *the most recent authority*, I am free to admit, places the apothecary under certain circumstances on a level with the physician or surgeon *on board ship*. Whatever be the meaning of this provision, surely the "Dublin Practitioner" will not maintain that the pure apothecary, without any other licence of a medical or surgical nature, is qualified to treat the diseases and affections which occur at sea; neither can he argue that, because of this provision, the Apothecaries' Company is entitled to grant medical degrees.

From the foregoing, you will perceive that the old authorities, including the time at which the Apothecaries' Act was passed, make no reference to the apothecary as a practitioner in medicine or surgery, and that it is only during recent times, when surgical or medical qualifications are obtained by the apothecary, that any such allusions are made. I am, &c., A SUBSCRIBER.

SCARLATINA MALIGNA.

To the Editor of the Medical Circular.

SIR,—Scarlatina is so common a disease, that even severe cases of the "Anginosa" species are not worth recording; but the following case of "Scarlatina maligna" was of so aggravated a character, and of such a rapidly fatal termination, that it may be assigned a place in your scientific journal. Similar cases are now fortunately very rare, owing chiefly to the attention paid in the present day to those sanitary laws which influence so greatly the health of communities.

On the afternoon of the 24th February, 1859, I was called to see a lad of the name of Russell, about nineteen years of age, a farm-labourer in the vicinity, of a healthy constitution, and always in the enjoyment of good health. I found him labouring under symptoms of a very low typhoid type: pulse weak, thready, about 140; tongue moist, coated with a dark brown fur; papillæ of a deep red, and enlarged, especially at the tip and the edges; face pale; lips livid; eyeballs sunken, with dark-bluish circles underneath the lower eyelids; features of a pinched, anxious expression; headache, especially in occiput; intellect clear; bowels then confined; skin about the natural temperature in chest and abdomen, bu

below it, in the extremities, with a few small dark permanent petechiæ scattered over the body, but chiefly over chest and abdomen ; skin inclined to be of a light livid hue, but *no eruption* observable ; great pain and difficulty in swallowing even liquids ; enlargement and tenderness of the salivary glands, affecting the speech ; throat greatly inflamed ; tonsils, uvula, and upper part of pharynx, swollen, ulcerated, of a dark livid colour, and chiefly covered with dark grey sloughs ; breath fœtid ; thirst ; urine scanty, of a port-wine colour ; no vomiting, nor pain in epigastrium ; no appetite ; feeling of great depression ; pains in back and limbs, and in the bones of the whole body ; occasional severe rigors and flushes of heat. The disease appeared to be concentrated chiefly in the throat. He stated that though he had for a week previously felt languid, weak, indisposed for work, with loss of appetite, pains in his bones, and chilly sensations now and then, yet it was only on the night of the 23rd that he felt really ill, having then been seized with violent fits of chilliness, and with great soreness of the throat, and that he had attempted to work even on the morning of the 24th, but had been compelled to take to his bed about noon of that day. I also elicited from him that about ten days previously he had in his neighbourhood visited a house, two or three times, where there was a mild case of scarlatina, then rapidly recovering.

On the 25th February, all the above symptoms, which presented themselves yesterday, had become much aggravated ; but still no eruption on the body ; intellect clear ; throat intensely inflamed and ulcerated, with dark grey sloughs ; bowels now loose ; stools watery, frequent, of a tarry colour, but without blood in them ; great dyspnœa, and sense of suffocation, &c. &c.

On the morning of the 26th February, about 8 a.m., for the first time a diffused eruption of a dark dingy colour, almost purplish, suddenly appeared, confined entirely to the chest and the abdomen. After showing itself for about three hours, it as suddenly receded, and was followed by an *exacerbation* of all the symptoms, of the dyspnœa, sense of suffocation, impossibility of swallowing even liquids, of the prostration, of the diarrhœa, &c. &c. He gradually sank, and expired at 2 p.m. of the 26th February, having thus died about forty-eight hours after I had seen him, and having continued his work even till the morning of the 24th inst.

The usual remedies and appliances were employed, such as cold to head, blistering of temples and nape of the neck, counter-irritation of throat, constant application of heat to body and extremities, strong beef-tea, warm drinks, brandy and and other stimulants ; a mild alterative laxative at first, along with diffused stimulants, diaphoretics, and narcotics and diuretics, such as camphor, ammonia, sp. æther. nitros., ipecacuan, Dover's powder, hyoscyamus and opium, and saline mixtures, and gargles of alum and of the mineral acids, &c. &c.

This case, though derived from one of a mild type, was of the most malignant character. It is worthy of remark, that there were neither vibices, nor any discharge of blood from the different emunctories ; that there was no affection of the chest, nor of the head, the intellect being clear to the last ; and that, from the eruption being alight and evanescent, the virulent poison of the disease, though *also invading the mucous coat of the intestines*, appears to have concentrated itself chiefly in the throat.

Robertsbridge, Sussex, June 22nd, 1860.

REFORMED ROMAN OR ORIENTAL BATHS.

To the Editor of the Medical Circular.

Sir,—Your contemporary, the 'Lancet,' seems to have lately dissected the merits of the so-called "Turkish Baths," not with much penetrating point. The 'Dublin Medical Press' of the 20th June, with the far-seeing eye of that *oculist*, said of the 'Lancet' article—"Hard to say [to see] whether this is eulogium or irony." One would expect that these coeval companions in antiquated ideas would understand each other better upon the works of antiquity. The 'Lancet' traces up very correctly these ancient baths to pre-Christian times—to their origin in ancient Rome and Britain. It clearly shows that before Mahomet was these baths were, as their magnificent ruins so fully attest. Why, then, does it call them "Turkish?" Are Celtic Britons and Anglo-Saxons to learn personal purification by the bath, as a religious rite, from the Turks? Is the sick Sultan to teach the brave Britons how to be clean, strong, and healthy? Why not recall these ancient household institutions, the Baths of Britain, from the tomb of oblivion, and confer upon them their old—their proper name ; or (as they are to be revived in an improved form, divested of all the abuses of the ancient Roman and the modern Turkish Bath) why not style them "The Reformed Roman or Oriental Baths" —"Thermo-Electrical Temples of Health?" By this title we get rid of the Mahomedan and the Pagan institution, and we revive a national household institution under a title worthy of a Christian nation. The 'Lancet' is in error if it supposes that "the restoration of the Turkish Bath has been amongst the consequences of the Crimean war." I shall repeat a few facts from my lecture delivered on the 12th March, and reported in the 'Sligo Champion' of the 24th March last. "...Mr David Urquhart, formerly M.P. for Stafford, and Secretary to the British Embassy at Constantinople, whose work on the 'Pillars of Hercules' so enlightened the people of the United Kingdom, that to him is due, before all others, the grand idea of the revival of the ancient Roman Bath in this country." "On the 7th June, 1856, the foundation-stone of the first Turkish Bath was laid in Dr Barter's establishment in Blarney, when the brother of the Duke of Leinster presided, and Dr Barter said 'that he had placed at Mr Urquhart's disposal all the materials necessary for the building.'" Mr Urquhart remained for some months there to direct the operations, so that to him is due the first place in establishing these national institutions in this country. He imported the grand idea, and by the invitation of Dr Barter gave it typical form in Ireland first, by means of workmen, money, and materials, which Dr Barter supplied. Never was there an institution that progressed more rapidly. Sixteen of them were erected in Ireland, representing £36,000 of capital, and one hundred of them established in England already. Dr Haughton also advanced the good work by those scientific papers on the Oriental Bath he read before the British Association and Dublin Society. He also visited Constantinople to observe their action and construction there. To Mr Urquhart for the idea, and to Dr Barter for the capital and the energy, the nation is indebted for these "most useful medical adjuvants," as Dr Corrigan considers the Turkish Bath of the East, with more vapour, would be ; but it appears that the Orientals have acknowledged the improvements on their baths, introduced by the Bath Medical Authorities, in this united kingdom, by Dr Barter and others.

It is true that some slight opposition to the improvements introduced, namely, to the use of a dry hot-air bath in preference to a humid air or vapour bath, has been offered, but which seems to have been silenced by the more scientific statement to be read in the works of Dr Carpenter, Dr Todd and Mr Bowman, Dr Millar, and of the late Dr Armstrong. It appears also that the most favourable reports are given of the beneficial influence of the hot-air bath in the two last Reports of the Newcastle Infirmary, which I have read with much interest. I shall quote from these Reports. "The temperature ranges from 130° to 160°, according to the nature of the disease, state of the circulation, and the condition of the patient." In some cases of heart-disease, patients have undergone the process with unlooked-for benefit. "The ordinary hot-water bath either induces or prevents relief from palpitation of the heart." "Internal congestions are relieved, and an equality of circulation brought about, by this hot-air bath." Dr Armstrong said, that the hot-air bath will bring pounds of blood to the surface which were suffocating some internal organ. The 'Lancet' states, "that when incautiously employed by persons liable to congestion of the head or *organs* of the chest (lungs and heart), it is not free from dangers." It would seem from the foregoing that the 'Lancet' and the Doctors differ. The Newcastle Infirmary Report sets forth the great value of this "in rheumatism, dropsies, skin diseases, influenza, catarrh, ague, the chronic bronchial affections of old people, and in pulmonary consumption ; for the hot-air and cold douche tend to check the sweats."

These hot-air baths have been found infallible remedies in the treatment of cattle-distemper (pleuro-pneumonia, as it is termed). At a late meeting of the Royal Agricultural Society, Dublin, Capt. Ball mentioned that one farmer lost in the South of Ireland thirty cows—all his stock. He was set up again ; his second stock was all attacked, but by means of the hot air-bath, under Dr Barter's advice, all recovered and resumed their milk in ten days.

I have attempted to unfold the nature and treatment of this mysterious disease in my essay on the Reformed Roman or Oriental Baths, which I shall briefly state here. Cattle-distemper seems to be a pestilential poison of the blood which produces lung complication. The blood-poison is the proximate cause, the lung-disease the proximate effect. Nature, which is the physician of all diseases, sends the blood in larger quantity, and in more acrid quality, to be depoisoned in the lungs ; but its acrid quality and increased quantity produce inflammation and congestion of lungs and pleura. Precisely as in cholera the vomiting and diarrhœa mask and obscure the blood-poison, so does pleuro-pneumonia mask and obscure the blood-poison of cattle-distemper. As the lungs and skin are the life-guards that co-operate more or less in the purification of the blood, our efforts should be to excite copious perspiration through the pores by means of the hot-air bath, and thus relieve internal congestions and inflammations. By this means we treat the blood-poison and the lung complication ; whereas by the empirical practice of bleeding, calomel, tart. antimony, &c. we attempt to treat only the one. I am inclined to believe that this thermo-electrical bath will yet be found as useful in the removal of cholera blood-poison, as it is now ascertained to be for cattle-distemper ; for we should in both diseases aid Nature's life-guards, the skin and lungs, to eliminate the blood-poison. Moreover, in spasmodic cholera, the patient becomes so deficient of animal electricity, that Nature, by the extraordinary efforts of muscular spasms, tries to reproduce more ; for muscular action signifies electro-genic action. We should aid these efforts by the thermo-electrical hot-air baths, which are calculated to develop and return electricity within and upon the surface of the body ; while, as vapour and warm water are good conductors of electricity, they would rob the living body of its due supply, and thereby exhaust the physical powers.

How beautiful is the animal economy of Nature in cholera! Her first effort is to eliminate the blood-poison by vomiting and diarrhœa : in doing so, she becomes exhausted of her electro-excitant sanguineous salines ; for want of these animal electricity becomes deficient, and, in consequence, there can be no *electro-chemical* union of the carbonaceous materials of the blood with the supporter of combustion, and, in consequence, animal heat becomes deficient, and the collapsed patient becomes colder than death. Nature by her extraordinary efforts of muscular action—spasms—endeavours to develop muscular electricity, for electro-chemical action and animal heat. The Book of Nature is the book of books ; all others are second-hand to her.

Electricity—that physical soul of matter and vital agent of Nature, which extends beyond the confines of our atmosphere into infinite space, keeps the whole planetary system in normal equilibrium, shakes the clouds in thunder, and, under favourable circumstances, will burn coke under water, and oils, with a brilliancy that could only be surpassed by the sun, and sufficiently luminous to strike off our second selves photographically—performs within the little world of Man in all the parts the drama of animal life, assuming simultaneously each and every character, and acting to perfection in all the vital functions, and ending in the tragedy of death. The human machine may, therefore, be regarded very fairly as electro-magnetic and magneto-electric ; for all the vital functions are electro-chemical in their nature and effects. The muscular system is an electro-genic apparatus. The intermuncial function of the nervous system is a magneto-telegraphic motive power ; for, what is physically felt in the extremities is psycho-physically acknowledged at the central seat of consciousness—the sensorium. The lungs and skin are electro-positive, and the liver and bowels electro-negative. Electricity can

operate as a cathartic, expel blood from a bleeding vein and beer from a barrel, and, upon the same principle, expel perspiration through the pores of the skin. When we sleep on feathers and blankets, we are more refreshed, because they are non-conductors of electricity, and therefore are well calculated to retain it upon our bodies. Upon the same principle, "dry vapour" hot-air baths are to be preferred to vapour or warm-water baths; for the latter being good conductors of electricity, exhaust the system of its due supply, and therefore exhaust the physical strength of the man. The strengthening effects of these thermo-electrical baths are being established by the pugilists and pedestrians who frequent them, and we may expect shortly to hear that they will be had recourse to in military training and discipline, to promote the psycho-physical health and the athletic energy of soldiers, and thus fortify them for the fatigues of war. The physician who can establish these facts may be regarded as the most important life-guard of a nation, for these would become the most formidable elements in the profession of arms, and in the art of war.

It seems absurd to send consumptive patients to warm climates when they can have higher thermo-electrical temperatures at home, at less expense to their physical strength and to their pecuniary circumstances. A foreign clime is common to all—may therefore agree with some and disagree with others; whereas if the high temperature of the bath disagree, you can leave immediately—but not so quickly the hot climate. When we consider the enormous mortality from tubercular disease in which people are dragged up into life and dragged out of it, or consigned to the indiscriminate use of cod-liver oil—which is capital food for Laplanders, but is gross, luscious, and disordering to the delicate stomachs of more refined Englanders or Irelanders—we have good grounds to consult Nature's tastes and feelings more, and rely less upon the medical drug art, and to ask ourselves, do we live according to the laws of Nature? We fear not. How few reach the full term allowed to man! What can be more saddening than the vast number of verdicts after sudden head or heart attacks, "Died by the visitation of God," or "from natural causes"? although the whole life of the deceased was a living contradiction to all the laws of Nature, and the Divine precept of personal purification by the thermo-electrical bath—so suicidal and self-poisoning that the living body carried its own corpse in a mass of morbid matters which should be eliminated regularly weekly. The horse is well cared for; but the man, the lord of creation, is neglected by himself.

The true way to fortify the constitution against disease from within or from without, is to practise the physical virtue of personal purification by the bath. Those who neglect this may fancy themselves healthy because not suffering, but in reality are like ripe fruit, ready to fall victims to the first epidemic storm—meanwhile are moving mines of undeveloped disease. For, in consequence of neglect of the sanitary code, the leaven of epidemic disease will ferment the stagnant materials, the dross that accumulates and chokes up the cuticular sewerage of the skin. As the vital germs of animals and plants superintend the construction of their own typical forms, according to Divine design, by means of the three vital workmen, heat, light, and electricity, from the three materials, air, earth, and water, we can also understand how each epidemic leaven will propagate its own typical disease by means of the same three vital agents, and from the same three materials, if they be morbidly accumulated within the living body. One pestilential germ will quickly propagate in such suitable soil, for a "little leaven corrupteth the whole mass."

It is due to the dignity of human nature to introduce man to himself—to his sublime essence Being, that Divine diamond-gem that sparkles in his soul with living light, and through which alone he is man and the lord of creation—in order that he may know what he is to honour with personal purification.

Man, then, is an immortal spirit endowed with light from eternity, and endowing flesh with life *pro tempore*. The living photographic image and likeness of the Almighty Creator is stamped upon the soul of the creature, conferring upon it immortality and the light of reason—that grand primal idea of Being which comprehends all other ideas, is the germ of intelligence that expands in the growth of the brain, and, under the influence of education, branches off into all the sciences to form the flourishing tree of human knowledge, that diffuses light over all the senses and their operations; enables man to embrace in an instant the past, the present, and the future; to triumph over time and distance, and, by the marvellous power of invention, to develop new wonders every day. Surely the living temple of this Divine light deserves to be kept clean—to be purified. Man, the living likeness of his Almighty Maker—the epitome of the universe—the beauty of this world—the living testimony of two worlds, of one within the other—the noblest study of mankind,—"Man should keep his house in order," even though it occupied two hours once or twice a week.

I am, &c.,

Sligo, 30th June, 1860. J. TUCKER, M.D.

OUR NOTE BOOK.

COAL-TAR AND PLASTER.

At Milan, M. Jacquemont particularly used Messre Corne and Demeaux's powder with the wounded affected with hospital gangrene, and no other agent appeared to him so convenient, prompt, or efficacious as coal-tar and plaster. He prefers it to perchloride of iron, and even to iodine, from which, however, he also derived great advantages. The reason is, he says, that both these substances remove, at each application, a thick layer of flesh, that the depth of the eschar to be obtained cannot be measured with precision, that the wound continually becomes deeper, and thus subsequently considerable time is required to fill up the cavity formed at the expense of the sound flesh. The disinfecting powder, on the contrary, removes the decayed part, without increasing the depth of the wound. Under this layer appears, after a few days, a wound of a roseate and fresh-coloured hue, without any inflammatory appearance, much healthier and more prompt to heal than when the sore has been dressed with lint impregnated with iodine. To these advantages, it unites that of occasioning no pain and no apprehension to the patients, who dread the transitory pain induced by applications of iodine. Nothing should, however, be excluded; all acids, in general, have a salutary action on wounds invaded by hospital gangrene. The best, in M. Jacquemont's estimation, are lemon-juice and vinegar. The application of one in preference to another is a matter dependent upon individual predispositions; a patient on whom one acid has remained powerless will suddenly find himself better from the use of another.

The author then enters into interesting details on the utility of substantial and healthy diet, with a view to obviating and attenuating the fatal effects of protracted and copious suppurations.

From the outset, M. Jacquemont became convinced, during his attendance on some of the Austrian wounded, that hospital gangrene preferably exercised its influence on debilitated constitutions, whereas the most robust or the best-fed men more surely escaped its disastrous influence. Enlightened by this remark, M. Jacquemont prescribed a tonic diet for his patients. Their ordinary food was mutton-chops, veal cutlets, beef, chickens, and other nutriment equally substantial, and almost always roasted. M. Jacquemont did not even hesitate to recommend a little wine, merely checking feverishness or inflammation, if either arose, but not fearing to feed his patients. Not only did the wounded under his care survive the suppuration, often copious, in wounds complicated with hospital gangrene, but not one of them suffered from the diarrhœa commonly so obstinate in such cases. Two at most were attacked with inflammatory fever, and even this symptom did not manifest itself until the gangrene, entirely cured a first time, was on the point of suddenly breaking out again the following days.

REMARKS ON SECONDARY AMPUTATION AFTER INJURIES CAUSED BY FIRE-ARMS.

M. Jules Roux read a paper before the Academy of Medicine entitled "Remarks on Secondary Amputation after Injuries caused by Fire-arms, from cases observed at Saint-Mandrier on the wounded of the Army of Italy." Primary amputation, of course, was extensively resorted to in this short but bloody war. 220 men, who had suffered amputation either on the field of battle, in the ambulances, or the adjoining hospitals, were admitted into the wards of Saint-Mandrier. Secondary amputation also was frequently instituted, 26 operations of this latter kind being performed at the Toulon hospital. M. Roux here remarks that one of the characteristics of the recent Italian war was the very extensive application of conservative surgery; a circumstance which afforded him an opportunity of studying, with greater attention than has hitherto been bestowed upon the subject, the consequences of the injury of the bone. One of these consequences, which M. Roux more specially noticed in his paper, and which has led him to adopt a novel practice, is the inflammation of the bone, which he denominates osteo-myelitis. At first local, osteo-myelitis gradually extends and occupies the entire osseous substance, following a parallel course with the inflammation of the soft parts. M. Roux describes three stages—congestion, softening, and suppuration—to each of which respectively correspond three significant expressions—resolution, amputation, and death. Let us suppose, says this surgeon, that osteo-myelitis sets in several months after the infliction of the injury, and occupies the entire extent of the bone: the life of the patient will be placed in imminent jeopardy, and the surgeon has the choice but between amputation of the limb, resection, or disarticulation. If amputation in the continuity of the limb be resolved upon, it is certain that the disease will not be integrally removed; a circumstance which doubtless accounts for the fearful mortality of secondary amputations, so great that, in 15,000 instances, M. Ribes declares never once to have found a single operation successful. In amputations in the continuity of the limb, performed at Saint Mandrier, death almost invariably ensued, and post-mortem examination showed that the entire bone was affected with inflammation; so that, no matter how high up the operation might have been performed, a portion of the disease must have inevitably remained. When, therefore, this painful experience had taught that osteo-myelitis of the entire bone was the evident cause of the fatal issue of these partial amputations, M. Roux altered the precept, changed the seat of the operation, and recommended its performance in the joint immediately above the injured bone. From the time this new system prevailed, the results were immediately different. 22 secondary disarticulations were performed, and although the cases were of the most severe character, 22 cures were effected, thus: amputations in the hip-joint, 4; in the shoulder, 13; in the knee, 1; at the ankle, 3; in the finger, 1. These operations, which in 20 instances had been necessitated by gun-shot wounds, were all performed through indurated textures, by the flap method, and with the assistance of chloroform, inhaled from M. Roux's *bag*, or from the *cornet* recommended by M. Raymond, Inspector-General of Naval Hospitals.

From the above, M. Roux considers himself justified in concluding:

1. That osteo-myelitis inevitably follows gun-shot wounds, but most generally has a favourable termination.

2. That it usually more or less promptly invades the entire bone—a general pathological fact.

3. That secondary amputation of the limb, or resection, too often exposes to the incomplete removal of the disease.

4. That to these partial operations are referable the incomplete results which lead to the death of the patients, and are perhaps the chief cause of the fatal issue of secondary amputations in general.

5. That during the six and perhaps the twelve months which follow gun-shot wounds, when a cure is not effected, and an operation is necessary, the surgeon should in most, if not in all cases, remove the diseased bone from its socket, and abandon the practice of partial amputation and resection.—*Journal of Practical Medicine and Surgery.*

APPOINTMENTS.—Dr G. N. Edwards has been appointed Assistant-Physician to St Bartholomew's Hospital. Mr E. C. Hulme, F.R.C.S., has been elected full Surgeon to the Central London Ophthalmic Hospital.

DR ROBERT C. WILLIAMS, OF DUBLIN.

The Irish Medical Profession has sustained a serious loss by the death of Dr Robert C. Williams, late President of the Royal College of Surgeons of Ireland, and representative of that body in the General Medical Council. Dr Williams occupied a large place in the affections of those who knew him as a private friend, and enjoyed the unlimited confidence of those who intrusted themselves to his professional care. He was a highly-accomplished physician and surgeon, and extensively learned in his Profession. For many years he was one of the ablest contributors to Medical periodical literature. In the 'British and Foreign Medico-Chirurgical Review' his pen was frequently employed. The sudden death of such a man at the comparatively early age of fifty-two is an event well calculated to inspire feelings of deep regret.

Dr Williams entered Trinity College at a very early age, and his career was distinguished. He subsequently studied under the late Abraham Colles. Afterwards he passed several years on the Continent, visiting and enlarging his knowledge at the various hospitals. It was during this period of his life that he laid the foundation of his future eminence as a surgeon. He settled in practice in Dublin about the year 1830, and very soon started to the front rank among the men of his time. In 1836 he was elected Professor of Materia Medica in the Royal College of Surgeons in Ireland, but previous to that date he had acquired a solid reputation as Lecturer in the Medical School in Digges street.

In 1838 the deceased became one of the Surgeons of the City of Dublin Hospital. Great kindness to the sick eminently distinguished him. His consideration for their feelings endeared him to them. With the students he was an especial favourite, and he at all times freely and unostentatiously communicated to them the results of his close observation, his large experience, and extensive reading. His colleagues, too, esteemed him highly. In difficult and obscure cases his opinion was sought for, and valued all the more because ever given with candour and humility.

In 1844 he was placed upon the Council of the College of Surgeons, and henceforth took a leading part in all its proceedings. His unvarying good temper, his knowledge of the laws of the College, his enlarged views of the interests of the body, and the accurateness and facility with which he expressed his ideas, rendered him one of the most valuable members of the learned Institution, and his opinions were always listened to with deference. Upon the occasion of a conference between the College of Surgeons of England and Ireland, on a subject interesting to the Profession, Dr Williams spoke so lucidly and forcibly, that the President of the College of Surgeons of England expressed himself in these words:—"The College of Surgeons in Ireland should feel proud of such a man."

In 1855 Dr Williams was elected Vice-President of his College, and in the following year he was unanimously called on to take the place vacated by the lamented Crampton.

One additional proof of the esteem and confidence of his brethren was given, when, in 1858, they sent him to London as their representative to the General Medical Council. It was felt that the Profession did not contain a man who would perform the important duties of the office with greater zeal and efficiency. It was while engaged in fulfilling these duties that he died.

Dr Williams's health began to fail a few years ago, after the death of his only daughter, to whom he was devotedly attached. Within the last two years it became obvious to his friends that he was failing. So lately as a year ago, however, there was no ascertained disease of a vital character. It was only during the past winter that the affection of which he died developed itself. When he arrived in London, however, nothing sudden was anticipated, and the sad event has taken all his friends by surprise. Immediately on hearing of the occurrence, the Council of the College of Surgeons met to express their sorrow and their condolence with the family of the deceased. They have also resolved to place Dr Williams's bust in their hall.

The funeral was most numerously attended by Professional and private friends.—'Medical Times and Gazette.

Births, Marriages, and Deaths.

BIRTHS.

CUOLAHAN.—June 16, at Grange road, Bermondsey, the wife of H. Cuolahan, Esq., M.R.C.S.E., of a son.

INGHAM.—June 20, at Haworth, Yorkshire, the wife of Amos Ingham, M.R.C.S. and L.S.A., of a son.

MARSHALL.—June 10, at Chard, the wife of T. Harrison Marshall, M.R.C.S. Eng., L.S.A. Lond., of a daughter.

STEPHENSON.—June 24, at Nottingham, the wife of T. Appleby Stephenson, Esq., M.R.C.S., of a daughter.

WILLETT.—June 14, at Bristol, the wife of M. Willett, Esq., M.R.C.S.E., of a son.

MARRIAGES.

SHORTT—BLYTH.—June 6, at St George's, Bloomsbury, John Shortt, M.D., M.R.C.P., &c., of the Madras Army, to Ellen Julia Anne, only daughter of the late Alexander Blyth, Esq., Surgeon of H.M.'s ship 'Unité.'

WALKER—SEABROOK.—June 21, at St George's Church, Hanover square, Thomas Houghton Walker, M.D., of Tolleshunt D'Arcy, Essex, to Ellen, youngest daughter of the late Thomas Seabrook, Esq., of the same place.

DEATHS.

ANDERSON.—June 19, at Edinburgh, Andrew Anderson, M.D., formerly Surgeon in the 92nd Highlanders.

BROWN.—June 9, at Braco, Logiealmond, Perthshire, John Brown, A.M., Student of Medicine.

BUCKLAND.—June 24, at Shaftesbury, aged 67, James Lush Buckland, Esq., M.R.C.S., and for twenty-seven years Surgeon to the Queen's Own Regiment of Dorset Yeomanry Cavalry.

CHURTON.—June 13, at Waterloo, near Liverpool, Joseph Churton, M.R.C.S. Eng.

CRAIG.—June 13, at Strathaven, Lanarkshire, William Craig, L.F.P.S. Glasgow.

GARMAN.—June 23, at Bow, Middlesex, Henry Ereth, aged 10, eldest son of Henry Vincent Garman, Esq., M.R.C.S.

LOMAX.—June 13, Charles Lomax, of Weobly, Herefordshire (in practice prior to 1815), aged 74.

LENOIR.—Adolphe Lenoir, Surgeon to the Necker Hospital, has just died at Paris, after a long and painful illness, at the age of 58. He occupied a most distinguished position in the French Medical scientific world, and was one of the founders of the now famous Anatomical and Surgical Societies. He has left an important work upon 'Enchondromæ' unfinished, which will be published.

LEWIS.—June 22, John P. Lewis, of Sheffield, M.R.C.S. Eng., L.S.A. Lond., aged 50.

LORIMER.—June 20, at Tyne park, Haddingtonshire, William Lorimer, M.D. Univ. Edin., L.R.C.S. Edin., aged 22.

MINES.—March 23, at Hobart Town, Thomas Mines, Assistant-Surgeon 40th Regiment of Foot, aged 28.

MONTGOMERIE.—March 6, at Scone, Dr Montgomerie, late of Ladeside, Kilbirnie, Ayrshire, aged 66.

MONRO.—June 14, at Newport, William Monro, late of Dundee, M.D. University of St Andrew's, L.R.C.S. Edin.

NEVILLE.—June 20, at Great Brunswick street, Dublin, Arthur Richard Neville, M.R.C.S. Eng., L.R.C.S. Ireland, L.K.Q.C.P. Ireland, aged 52.

ROWAN.—April 10, at Richmond, New South Wales, Robert R. Rowan, formerly of Dundalk, Ireland, aged 75.

THOMSON.—June 22, at Arnaddy, Oban, Alexander Forbes Thomson, of Easdale, Oban, Argyleshire, L.F.P.S. Glasgow.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS.—At the Comitia Majora, held on Monday, June 25th, the following gentleman was admitted a Fellow of the College:—G. Land, M.D., Madeira. At the same Comitia, the following gentleman, having undergone the required examination, was admitted a Member:—W. Edward Robbs, M.B., Stamford. The following gentlemen were also admitted Members of the College, having been previously elected under the expired temporary bye-laws:—John Gallagher, M.D., Royal Navy; Clarence Cooper, M.D., H.M. Madras Service; James C. de Castro, M.B., Madeira; W. R. E. Smart, M.D., R.N. Hospital, Bermuda; William James Whyte, M.D., Banff; Richard Ford Foote, M.D., Constantinople; Francis Isaiah White, M.D., Perth; Joseph Marcus Joseph, M.D., Madras; Elias Jones Roberts, M.B., Bengal; Henry Francis Williams, M.D., Bengal; W. C. B. Eatwell, M.D., Calcutta; Joseph Fayrer, M.D., Calcutta; Edward Ferrand Astley, M.D., Dover; George F. Bone, M.D., Calcutta; John Jones, M.D., H.M. Indian Army; William Carey Coles, M.D., Bombay; James H. Simpson, M.B., Pontefract; Thomas L. Rogers, M.D., County Asylum, Rainhill; Charles Elam, M.D., Sheffield; Alexander McKechnie, M.D., Southsea; T. W. W. Smart, Northiam, Sussex; Peter Eade, M.D., Norwich. This being the Annual Meeting, the following officers were elected for the ensuing year:—President:—Thomas Mayo, M.D. (re-elected).—Censors: Dr Barlow, Dr F. Weber, Dr Gull, and Dr T. K. Chambers.—Treasurer: Dr Alderson (re-elected).—Registrar: Dr Pitman (re-elected)

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the Diploma, were admitted Members of the College at a Meeting of the Court of Examiners on the 22nd inst.:—William Henry Brecknell, Gateshead, Durham; Henry Croucher, Bexley, Kent; Augustus Frederick Elliot, Exeter, Devon; George Harrison, Grosvenor street, Grosvenor square; John McDonnell, Milton road, Stoke Newington; James Mark Morris, West Bromwich; Christopher Williams, Williton, Somerset.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practice, on Thursday, June 21:—Thomas Young Baker, Hargrave, Northamptonshire; Robert Cummings Gibb, Newcastle-on-Tyne; John Jones, Llanfyllin; Raphael Meldola, 25 Gretton terrace, Victoria park; William Mitchell, Bothic, Cumberland; Robert Tanner, Gloucester house, Ledbury; Henry Ubsdell, Pewsey, Wilts. The following gentlemen also on the same day passed their first Examination:—Sebastian Claudo Thomas Gardner, Highgate; Edmund Cornish King, University College; Richard May Miller, University College; Timothy Richardson, London Hospital; William Bathurst Woodman, London Hospital.

EXAMINERS IN MIDWIFERY OF THE UNIVERSITY OF LONDON.—Dr Barnes, Dr Priestley, and Dr Graily Hewitt are candidates for the vacant appointment.

AMONG the Civil Service Estimates for this year are 11,500*l.* for Dr Livingstone's expedition; 4,000*l.* for quarantine expenses; 7,000*l.* for the Niger expedition under Dr Baikie.

ST JAMES'S PALACE, JUNE 20TH.—The Queen was this day pleased to confer the honour of Knighthood upon James Ranald Martin, C.B., F.R.S., Physician to the Secretary of State for India in Council, and Surgeon in the Bengal Army, retired.

SOIREE.—The College of Physicians of London will this year give a *soirée* at the College on the 9th of July.

MILITARY FLOGGING.—During 1859 there were 22,665 lashes inflicted on soldiers in the British army stationed at home.

INTERNATIONAL STATISTICAL CONGRESS.—A meeting of the Commission for Organising the Fourth Session of the International Statistical Congress, to be held in London this month under the auspices of her Majesty's Government, took place recently at Pembroke House, Whitehall gardens. A great many Commissioners were present. Our Profession was represented by the President of the College of Surgeons, Dr Guy, Sir J. R. Martin, Dr McWilliam, Dr J. Sutherland, and Dr W. Farr. The Organisation Commission, upon a report prepared by Dr Farr, decided upon dividing the Congress into six sections for the purpose of considering the various subjects which will be included in the programme—namely, Section I. Judicial Statistics; II. Sanitary Statistics; III. Industrial Statistics—two branches, Agriculture and Mining; IV. Commercial Statistics; V. Census, and Military and Naval Statistics; and VI. Statistical Methods. It is proposed to invite Lord Brougham, Lord Shaftesbury, Earl Stanhope; Lord Stanley, M.P.; Mr Hutt, M.P., and the Master of the Mint, to act as pre-

sidents of sections. The opening of the Congress was fixed for Monday, July 16, and the sittings will be continued over the five following days. The meetings will be held in Somerset House, the Council of King's College having placed their large hall and other portions of that establishment at the disposal of the Commission, while the Society of Antiquaries, the Geological Society, and the Astronomical Society have in a no less liberal spirit consented to allow their apartments in Somerset House to be used for the sectional meetings. Several suggestions were offered, evincing a strong desire to give the most hospitable reception to our distinguished visitors, and the Lord Mayor expressed a hope that they would do him the honour to visit the Mansion House. Mr Milner Gibson having thanked the Commission on the part of the Government for their co-operation in the endeavour to make the Congress as useful as possible to this country and to others, the meeting adjourned. It may be remarked that the object of the Congress is to promote the collection of statistics, especially those published officially by the different Governments, on the most approved methods and upon uniform bases, so as to admit of the international comparison of the results obtained. The first meeting of the Congress was convened at Brussels by the Belgian Government in 1853; the second session was held in Paris in 1855, and the third at Vienna in 1857.

Earlswood Asylum for Idiots.—The report by the Board of Management of this excellent Institution for the past year has just been issued. We are glad to learn from this document that an Asylum so invaluable to a helpless and much-to-be-pitied class of the community continues to prosper, and that the number of its supporters has largely increased. There are now 306 pupils in the establishment, to be increased to 326 at the next election. The healthy condition of the inmates is the subject of congratulation in the report, and the statement of the Medical Superintendent, appended to the report, gives a favourable account of the results of their mental and moral training. During the year bequests have been made to the amount of between 1,200*l.* and 1,300*l.*; the bazaar held at Brighton had also been productive of encouraging results, and not less so the anniversary festival, at which the Duke of Cambridge presided. The proposal to receive cases for life is strongly recommended by the Board of Management, who, in conclusion, congratulate the friends of the Asylum on having effected a work for the benefit of the idiot which has no parallel, and which has been sustained by a sympathy beyond all expectation.

French Surgery.—The question of resection of joints, studied for twelve years with so much interest and care by English and American Surgeons, is still little known in France. The resection of the elbow-joint has alone become part of our practice, that of the shoulder has been practised several times; but resection of the knee and the hip have hitherto met with few partisans.

The Association of Foreign Graduates urge the following reasons in support of their claims to registration:—"1st. Because we are legally qualified medical men already, and as such duly registered! 2nd. Because we obtained our foreign degrees *many years ago*, from legally-constituted foreign universities, on the good faith of written examinations, original dissertations, British diplomas, and other approved testimonials! 3rd. Because the Medical Act nowhere insists that such 'regular examination' must NOT be a written one; and nowhere demands that it must necessarily have been instituted at the university seat! 4th. Because, on the other hand, *the statute in question has actually provided a dispensation in our favour!*—*Vide* Sec. 46. Lastly. Because the judges of our superior Courts of Law have repeatedly, and in a marked manner, expressed their opinion that persons engaged in practice BEFORE the passing of the Medical Act *have just claims to some such concession;* and that the Senate in question should not be interpreted either RETROSPECTIVELY or oppressively; and, above all, because our junior brethren, who have purchased diplomas in this country, and even *since the passing* of the Medical Act, have been allowed to place SUCH qualifications upon the Register!!!"

Lahore Medical College.—The Punjab Government has published the prospectus of the Lahore Medical College, to which Sir Charles Wood has given his sanction. The Staff is to consist of a Principal, Professors of Medicine, Surgery and Chemistry, an Assistant Demonstrator, a Superintendent of the Hindostanee Class, and an Apothecary. The 1st Class is to comprise students who wish to be educated as Sub-Assistant Surgeons. Candidates will be admitted to study for a period of five years, after passing an examination in English and Arithmetic. The 2nd Class is intended for native Doctors, who will be enlisted as soldiers and placed under military discipline. They must be natives of the Punjab, and not under sixteen years of age. On entrance they must pass an examination in Hindostanee, Punjabee and Arithmetic, and then study for three years. The certainty of situations in the public service and of private practice among their own community, has made the medical schools in India most popular with the natives. The Lahore College will be equally so with the Punjabees, we believe. The error of educating the students in mere theory, committed till recently in Agra and Madras, should be avoided. Some Sub-Assistant Surgeons can talk science glibly enough, but cannot stop a hæmorrhage.

The Hot-Air Bath.—Mr Bolton, House-Surgeon, in his Annual Medical Report of the Newcastle Infirmary, where a hot-air bath, with frigidarium, tepidarium, and sudatorium, has been erected at the cost of only 60*l.*, speaks of its great value in cases of rheumatism (acute and chronic), dropsy, skin diseases, catarrh, influenza, and ague. He says, "In regard to the last-mentioned disease, I have several times witnessed the aversion of its paroxysms by placing the patient in the bath prior to the expected onset of the rigor. By this means alone the essential features of the disease have been removed, and quinine has then been used as an ordinary tonic for the remaining debility. The influence of the bath on persons in health is also interesting. After the very first impression of the high temperature is past, the sensation is rather agreeable than otherwise, and a few minutes elapse before any marked effect is observable. Before ten or twelve, however, are over, the perspiration will begin to stand in drops upon the skin, and the pulse to beat more quickly; in other ten or twelve minutes the pulse will almost have doubled itself, and the perspiration will run down the skin in torrents, and no doubt will be entertained as to the greatest luxury in the world being the cold douche; accordingly, after twenty or twenty-five minutes' tolerance of this temperature of 130 or more, resistance being no longer possible, a rush is made to the shower-bath, and its contents are brought down eagerly. The bather feels the cold intensely grateful, leaves the heated apartment under its influence carefully wrapped in a blanket, his pulse rapidly falls to its wonted rate, and he feels himself a very fresh, clean, hungry, and independent man."

APPOINTMENTS FOR THE WEEK.

Wednesday, July 4.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Obstetrical Society of London.—Mr Mitchell, "On some of the Exigencies connected with Preternatural Labour:" Short Papers by Dr Drage, Dr R. U. West, &c. 8 p.m.

Thursday, July 5.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2½ p.m.

London Home.—2 p.m.

Friday, July 6.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, July 7.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, July 9.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.

Tuesday, July 10.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

Omega.—It is not always easy to distinguish a fracture within the capsule in old people after a few days if much pain or swelling be present. Rest is the great remedy. Inflammation may go on, and be very difficult to subdue.

Mr Watson.—Certainly.

B. H.—We can see no reason why it should not be attempted.

An Old Correspondent.—The qualification cannot be registered.

Medicus (Reading).—1st. No.—2nd. No.

The Northern Whig.—Received.

Dr Tucker's letter received and inserted.

A. Z.—The Medical Council has not power to correct the evil. The Charter is granted by the Crown, but the Council is not obliged to recognise it. It is different with respect to the Midwifery qualification, and the licence of the Irish Society of Apothecaries. It is disputed whether the latter qualification is a sufficient one for the practice of medicine.

Amicus (Bath).—It shall be attended to.

Alepii (Carlisle).—We will answer it.

Dr W. B.—Yes.

M.R.C.S. Eng.—1st. No.—2nd. Next September.

A Subscriber.—It is a quackish affair, without any therapeutic value.

To the Editor of the Medical Circular.

Sir,—In your Notices to Correspondents, will you be good enough to reply, either in a condensed and inclusive answer, or in what remarks you may deem necessary, to the following questions?

1. Have the Medical Council any *legal* right to refuse Registration to L.R.C.P.s (Ed.), who were made so previous to August, 1859, by testimonials, and not by examination?

2. If the Medical Council, from the beginning, had that right, could the College of Edinburgh have had a *legal* right to make these non-examined Licentiates?

3. If the Edinburgh College had the discretionary right to do it, should they not support these previously-made Licentiates in demanding registration, though the College might subsequently submit to the Medical Council in consenting to make no more of them?

4. If the Edinburgh College gave these diplomas in ignorance of their having no power, or being indiscreet in offering them, do these Licentiates acquire nothing by their diplomas!

5. If the Medical Council of August, 1859, could *then* legally enact a restriction against the registration of such Licentiates, could *that* legally obstruct the registration of such Licentiates as were made so previous to August? If so, what defence is there for the *retrospective* restrictions?

6. Is it likely that the Medical Council would refuse the right of these Licentiates to memorialise or petition for registration?

7. If a non-examined Licentiate sign himself "Physician," or put it on his door-plate, is he liable to prosecution?

8. Or, if he insert himself in Churchill's 'Medical Directory' as L.R.C.P. (Edin.), would that be a *false pretence*, exposing him to prosecution?

9. Or, if he permit himself, by courtesy of others, to be styled "Dr" (not M.D.), is he liable to prosecution?

10. If he style himself Surgeon and Physician, being *registered* only as the former, is he liable to prosecution for the latter?

11. If the Edinburgh College had no right to do it, what is to be said for the error of making such Licentiates if it prove of no benefit in the result?

12. On what moral principle is it that the College can retain the fees (stamps excepted) if the non-examined Licentiates acquire neither legal nor courteous status by their diplomas?

Favouring me with the best answer you can, you will oblige a constant reader, and

Your obedient servant,

Inquisitor.

[We may observe generally upon these queries, that the Medical Council, in our opinion, could not refuse to register the persons in question until notice of a restriction had been given by the Privy Council. The phrasing of the clause is obscure, and it is doubtful whether the Order of Privy Council would be retrospective. The strict answer to your fifth query seems to be, that the registration would cease at the date of the Order, without reference to the time at which the qualification was obtained,—an injustice, no doubt, and we do not think a law-court would allow it.

Any man holding a licence of a College of Physicians may call himself Physician, whether registered or not, so far as we can judge from recent decisions; but all is doubtful on this point. What is law in one court is not law in another. It does not seem to us necessary to go further into the questions propounded.—Ed. Med. Circular.]

Mr Paterssen.—Article received, but we fear that we shall not be able to find room for it.

Mr Bermingham.—Received.

An Irish Surgeon's article touches too much on subjects of general policy to be suitable for publication in a scientific periodical.

Mr Palmer.—The advertiser was associated with the Bennetts, of whose proceedings this Journal gave a full account at the time of their dispersion. Read the Circular of March, 1859.

Letters received from J. Ewing, C. W. Finney, Mr Bean, W. Cole, G. Leith, R. F. George.

CLINICAL REPORTS.

FRACTURES OF THE SKULL WITH DEPRESSION. OUGHT THEY TO BE TREATED ALL ALIKE, OR WITH THE TREPHINE?—MR GAY, MR PAGET, MR ERICHSEN.

(Continued from page 2.)

The following is a case which sufficiently indicates the treacherous and uncertain character of these accidents, especially about the base of the brain. This was very strongly dwelt upon by Mr Hilton in his recent admirable Lectures.

CASE II.—A young man, apparently in perfect health, sustained an injury of the skull in the mesial line, from a quantity of bricks falling on it, and was admitted into St Bartholomew's Hospital under the care of Mr Paget shortly after the accident.

At first there were no symptoms either of compression or irritation: there was an ugly wound of the scalp; it was also ascertained that the bone underneath was fractured; the wound was therefore simply dressed. During the next four days the man did remarkably well, and was entirely free from cerebral symptoms. A shivering fit then unfortunately occurred, and was succeeded by difficulty in forming words, as well as by a most serious tendency to stupor, in which he became more and more insensible. Mr Paget therefore determined to trephine and use chloroform. During the operation, and after the removal of a thick piece of the skull, a dark-coloured clot was seen lying near the dura mater, which latter had given way at one spot. Some small portions of bone were taken away, but no large depressed portion could be found.

The various means used, especially the chloroform, seemed to have had little effect on the real seat of the mischief, which was obviously deeper than had been reached by the trephine, probably at the base of the skull, as subsequently retention of urine set in, and hemiplegia of the right side of the body. The poor fellow sank into a state of deep coma shortly after, which ended fatally.

It was rather unfortunate that the friends of the party would permit no post-mortem to be made; but there can be little doubt the nature of the accident was what we have already referred to, some extensive mischief involving probably the base of the brain.

The next patient is an average specimen of the class of cases of injury of the skull which do well, where the dura mater is not much injured.

CASE III.—A man, aged twenty-seven, with fractured skull, admitted into University College Hospital two days after the receipt of the injury of his head, was found by Mr Erichsen with the following curious history:—It seems that the poor fellow had come to hospital with his broken head two days previously, but being, as it was thought, stupid and only very drunk, and more under the delicate attention of a couple of blue-coated policemen, it was considered rather *selon les règles* that they would, after the manner of policemen—usually so moral—try him first and trephine him afterwards; the diagnosis, in fact, between deep cerebral disturbance from fractured bone, or the less formidable accident of gin, not being at any time clear in our cerulean police-constable's mind, or in that of some of our friends, the hospital "dressers." Nature had time to fight out the battle herself, without the trephine at first, and the man recovered during the delay incident to his going and coming to the hospital. No doubt the requirements of justice, too, were gravely satisfied.

When Mr Erichsen saw the poor man, he found, as just said, that the most serious cerebral symptoms had then continued for forty-eight hours. The man had applied soon after the accident, but being stupid or drunk, as it was thought, he was taken away, and on his road from the hospital became quite delirious and then insensible. It is, no doubt, difficult very often to say, in such cases—even for persons more astute than a policeman—where delirium ends and drunkenness begins; but a correct, gentle-minded surgeon will always rather err, far away, on the side of too much caution for his defenceless patient, than yield to the brutal instincts of mere police-officers, and make light of a very serious case. A person, too, very often apparently in perfect health, will get a trifling "reeling in his head:" or simple faintness or weakness. It is a thing of an instant; yet that has been an epileptic or apoplectic seizure—the man walks like a drunken man, yet he's not drunk. Mr Erichsen at once recognised this man's state: he was half comatose, his breathing heavy, but not stertorous; the pupils large, but acting a little when stimulated by light; there had not been time yet, perhaps, for much effusion. A fracture of the left parietal bone, with depression, was discovered, and after the usual careful precautions of shaving the head, &c., the trephine was cautiously applied; but, what we believe is most essential to the good result of such cases, the dura mater was not cut or injured; between the skull and the dura mater a clot of blood was found, and was at once removed.

Before evening of this day the man seemed much improved; as much from the rest in hospital, the previous use of venesection, purgatives, &c., as the removal of this clot. His recovery was without intermission, and he left the hospital well.

The careful surgeon will always keep in mind other dangers besides those of the immediate accident, such as death from the cutting operation itself, or pyæmia. (*a*)

CASE IV.—A man, aged forty-nine, was admitted to Guy's Hospital for compound fracture of the skull from the fall of a brickbat on his head. Paralysis of the left arm was detected; his intellect was clear. The paralysis of the arm persisting, elevation of the bone by the trephine was perhaps incautiously decided on; at least, if the results could have been foreseen, the trephine would not have been used: the dura mater was not originally lacerated, *but it subsequently sloughed*, and a so-called fungus of the brain appeared. The injury to the left arm pointed to some mischief at the right side of the brain, about the region of the optic thalamus, or other chief ganglia, too deep perhaps for the trephine to reach. This poor man died of pyæmia: the veins of the diploe of the skull were filled with pus; the right optic thalamus was the part of the brain chiefly diseased.

CASES OF STRANGULATED HERNIA — EVIL EFFECTS OF PROLONGED "TAXIS." — MR JOHNSON.

Cases of strangulated or incarcerated hernia are amongst some of the most delicate with which the Surgeon in every-day practice has to deal. The practice of some hospitals is to operate as early as possible; in others, to adopt the plan of "taxis" reduction by the use of ice, chloroform, &c. A French Surgeon, very recently, of an unpractical turn of mind, recommends, in a big book, the forcible use of the taxis; another Surgeon of high position (Desault), occasionally quoted by Mr Stanley, thinks, if the word "taxis" were blotted out of surgical literature altogether, more lives would be spared. Between these two extremes the Medical world seems blown about by every wind of doctrine. The following cases are suggestive. The first is a case of congenital hernia incarcerated or sacculated, but in which the practice of M. Gosselin proved anything but specific; the second case exhibits the usefulness of early operation.

CASE I.—J. L——, aged fifty-three, was admitted into St George's early in the present year, with some ill-defined affection of his rupture. The day before admission, he said, his hernia came down; he was sick soon after. A Surgeon to whom he showed the hernia, together with his assistant, endeavoured for more than two hours to reduce it by means of forcible taxis, as recommended by M. Gosselin; but not succeeding with the reduction, he came to hospital. When examined in the hospital, it appeared he was not suffering from symptoms of strangulation: there was no vomiting, no pain in the abdomen, nor tenderness on pressure; there was a large hernial tumour, the size of a cocoa-nut; it was not tender, but the whole scrotum was extensively ecchymosed from the violence of the taxis applied before admission. The House-Surgeon of St George's, not deeming it a case for operation, applied ice externally, which is found in inguinal hernia at this hospital more useful than the warm bath. Next morning the report was, he had passed a very restless night; he had vomited once, early in the morning; there was still no pain, and the tumour was soft, nor was it then painful, though a little later it became tender and he had pain in the abdomen. The poor man suddenly became collapsed, too, about mid-day; the face became shrunken and dark-coloured; the fingers were blue and cold; stercoraceous vomiting also now told of the mischief wrought by the excessive taxis before admission, and, as the less of two evils, operation was now decided on, a consultation having been held on the case; Mr Johnson wisely deemed it right to open the sac, and did so; when it was found to contain several ounces of bloody serum, some large clots of coagulated blood, and about eight inches of very dark intestine; all the tissues of the bowels were much thickened, and there was blood extravasated under the serous covering; there were also patches of extravasated blood in the mesentery. All this ecchymosis or injury was probably the result of the prolonged taxis. When the gut was returned, it was discovered that the hernia was congenital, as there was a large "diverticulum" at the lower and back part of the sac, into which the intestine had descended; there had been probably no real stricture, as the internal ring was of large size. The man rallied after the operation; the bowels were relieved three times; but the poor fellow sank during the night, and died exhausted.

One of the chief uses of the best Clinical Reports is, evidently, that out of the mistakes of other Surgeons, we, or men like Mr Johnson, may occasionally "point the moral" of the evil of such things as the excessive use of the taxis in instances like this. We hear the same story of the taxis in every one of the hospitals, especially at Guy's and at St Bartholomew's; still, it is difficult for the Surgeon in general practice to know what to do, if not to exert himself to force the gut to go back. The post-mortem in this case showed that the patient, in all probability, would have recovered, but for the rough method employed to reduce the hernia. On two previous occasions it had yielded to cautious, gentle use of the taxis and ice; and there is little doubt, if ice or chloroform had been used early in the case, all would have been well. The excessive "taxis" defeats itself; the gut becomes thickened, and pulled about, and enlarged.

The next case is one of a more satisfactory kind, where early operation probably saved the man's life.

CASE II.—A man, aged fifty, admitted January 13th at two o'clock in the day, was found to have a strangulated oblique inguinal hernia. The early history of the case did not present anything out of the common: he has worn a truss for fourteen years; he has never had any trouble in reducing or "putting up" the hernia. At ten o'clock in the morning of the day of admission, the hernia protruded, and, according to the notes of Mr Rouse, the industrious Surgical Registrar at St George's, it was larger than usual. The man had immediately severe pain in the abdomen; he endeavoured to push up the hernial tumour himself, but, finding the pain severe, he came to the hospital, when an oval tumour as large as a fist was found; tender, but not tense; not ecchymosed, as the former case. He had also been sick several times during the day; the pulse was 76, irregular and intermittent; he was restless and tossing about on his bed, the symptoms not improving.

The operation was performed at half-past four o'clock. The usual incisions having been made, the sac was laid open also in this case; the general impression in the hospitals now being, we think, that it really signifies little in a given number of cases, say 100 on each side, whether the sac is opened or not. The sac was opened, and eight or ten inches of dark congested intestine were seen. There was some bruising of the gut, apparently. The stricture, which was very tight, was divided, and the gut returned; the edges of the wound brought together by sutures, and water-dressings applied.

Although severe inflammation subsequently

(*a*) There appears to be not any the least shadow of truth or fact in the recent startling idea of the 'Medical Times' that chloroform leads to pyæmia. It would not be necessary to state this, but that journal still holds fast by this error, having once stated it; but it would be as wise for it to say arsenic-eating is true because people in the Tyrol use as a cosmetic oxide of zinc, or to say the arsenic in the trial of Smethurst was proved because it all along held that idea too.

attacked the sac, which went into suppuration, this patient did well, and left the hospital cured; all due, probably, to the comparative absence of the "taxis" and the early operation.

THE SPIRIT OF THE PERIODICALS.

The 'Lancet' opens with some clinical remarks by Mr SKEY on *Tetanus*. The Author commences with some general observations on the failure of remedies to cure tetanus, not denying that cases may occasionally recover, but teaching that no single class of remedies, either purging, sedatives, counter-irritants, &c., can be relied upon. He then reports the following case:

"A boy, aged fourteen, was brought into St Bartholomew's Hospital, with a hand greatly mutilated by machinery. The house-surgeon decided, on consideration,—and I thought wisely decided,—to make the attempt to restore the hand. For twelve days he progressed favourably. On the thirteenth, he complained of stiffness in the back of his neck. When I saw him, at the expiration of some hours, spasm of the muscles had extended to the chest and abdomen; but none of the muscles were severely or painfully contracted. Still the signs were distinct. The boy was the subject of tetanus; and as I had never had a successful case, I was the more anxious to adopt some more promising agent than any I had hitherto employed. With this view I determined to test the efficacy of the woorara poison, which had been employed with some effect by Mr S. Wells in three cases of tetanus. By the kindness of Mr Savory, who had a small quantity of the fresh poison, I was enabled to obtain sufficient for the purpose. We dissolved two grains in an ounce of distilled water. The boy being placed under the influence of chloroform, I amputated the hand immediately above the wrist-joint. My intention was to have applied two drops of the solution to the wound, and, observing the consequences, to have increased the quantity applied according to the effect produced. On recovering his consciousness, it was obvious that what had been done for the boy, whether the removal of the hand or the administration of chloroform, had been in the direction of good: the pulse had fallen from 130 to 100, and the rigidity of the muscles was greatly diminished, and continued so. The pain was also reduced, and the countenance was more tranquil. He could open his mouth to an extent sufficient for the introduction of food. The rigidity of the muscles was by no means great, nor did he suffer the degree of pain usually attendant on severe cases of tetanus. It is very true that the sterno-mastoids, pectorals, abdominal muscles, and, indeed, the muscles of his trunk generally, were involved; but their contraction was comparatively slight, and certainly was unproductive of considerable pain. The use of the woorara was postponed, and I ordered the boy tincture of opium, ten minims; compound spirit of ammonia, half a drachm; brandy, half an ounce, every two hours. On the following day I found he had had a tolerably good night: his pulse had slightly risen in frequency; the rigidity of the muscles had not increased; on the contrary, it appeared somewhat lessened. His countenance was more anxious, which appeared rather attributable to mental than bodily suffering, for he had only recently become cognizant of the removal of his hand. By two o'clock on that day, the boy had consumed four ounces of brandy, half an ounce of spirit of ammonia, and eighty drops of laudanum. Still I had no excuse for the trial of the woorara. Doubtless the boy was in a dangerous condition; but it was obvious that the condition was not attributable to the morbid contraction of the muscular system, but to something beyond it. His bowels were constipated. I ordered him calomel and jalap, castor oil, enemata of turpentine, croton oil in no insignificant doses; but I failed to obtain the desired result up to the time of his death. In other respects, the same treatment was continued. On the third and fourth days his condition was not materially changed. He took food without difficulty, as also his medicine at the required intervals. The ammonia was increased to drachm doses. On the fourth day, his pulse had increased to 135, and his countenance was more pallid. The rigidity of his muscles had not increased in any positive degree, and those of the extremities were entirely free from spasm. On the morning of the fifth day he had taken, without producing any marked effect on his system for good or for evil, about forty-eight ounces of brandy, one ounce of tincture of opium, and four ounces of spirit of ammonia. And we may form some judgment of the severity as well as the prostrating influence of the disease under which this poor boy was labouring, when we consider that such an enormous power was inadequate to produce the smallest impression on his system. On the last visit I paid, except that he appeared somewhat weaker, I cannot say that he was positively worse. He could open his mouth sufficiently wide for the introduction of nourishment, and he took food freely throughout the greater part of his illness. His pulse was a shade weaker, but not materially so. His spasms were not severe nor considerable, and assuredly they were not a source of pain. Of this the boy gave me full assurance on many occasions. On the evening of the fifth day he died. His body was not examined.

"If the nature of the disease we call tetanus could be ascertained by dissection, we should have acquired this knowledge long ago; but, so far as I know, we have obtained no information by such means, except negatively, on which to found a theory, or to obtain a guide to practice. The total amount of knowledge consists in this; that at varying intervals after the occurrence of more or less violent local injury, and occasionally—but in our latitude very rarely—independently of injury, we observe rigidity of the muscular system, commencing with the muscles of the jaw, and extending to the neck, trunk, and finally to the extremities; that it is accompanied by great pain in the contracted muscles, a quick pulse and respiration, and constipated bowels; and that it terminates, in from two to six or eight days, in death. Such is nearly the sum total of our knowledge of tetanus, and it may be doubted whether we are even now occupied in the right path of inquiry. We fix our attention on the local spasm of the muscular frame, as though that condition of the system constituted the essence of the disease, of which it is only a symptom. We rather search for remedies that will abate spasm, than for such as will attack its cause. The above case exemplifies negatively this fact. The boy died of tetanus, but not of spasm. At no period of his case was the contraction of his muscles so rigid as to cause pain of a severe character. He complained of his arm; he suffered from a sense of illness; he desired to be let alone, and not to be disturbed; his expression betokened serious illness; but he did not die from pain nor from spasm: he gradually sank from utter prostration of nervous power, which every remedy employed was incompetent to contend against. And it is by no means uncommon to observe, towards the close of life, that the most prominent symptom of the disease—namely, muscular rigidity—gradually subsides, while the real disease advances towards its fatal crisis. In the whole range of disease, I do not recollect any evidence of the existence of what we term the nervous system more remarkable or more conclusive than is derived from the influence of anæsthetics in tetanus. How absolutely is the morbid influence of the nervous system on the heart and respiratory system suspended by chloroform! and how suddenly too! The pulse falls to its natural standard, the equilibrium of respiration is restored, all expression of suffering subsides under the reality of tranquil sleep. So complete is the external manifestation of health, that it would astonish a bystander, ignorant of the nature of the case, to be assured that in a few days, possibly a few hours, it would terminate in death. Suspend the remedy, remove the influence of the anæsthetic agent, and the entire train of fatal symptoms start, as it were, into existence—the pulse rises, the respiration is quickened in proportion, and the muscular spasm, with its usually inseparable companion, pain, becomes again dominant. Nor do we observe that the disease, to whatever extent it may have reached, is retarded or even diminished by the treatment. On the contrary, its progress is unremitting; and both the violence of the spasm and the severity of the pain are regenerated with an increase of intensity proportioned to the duration of time during which they have been suspended by anæsthetic agency. In the above case, I was fully prepared to test the curative properties of the woorara poison, as recorded by Mr Wells and recent French writers; but I really had no excuse for its employment. The boy did not die either from or with spasm; and I cannot persuade myself that we shall ever discover in the woorara poison a curative property capable of rousing the vital powers, already oppressed by mysterious morbid actions going on within the frame. Still, I am quite prepared to acknowledge that all reasoning, more especially on a subject so obscure as tetanus, sinks in comparison with practical observation. Other authorities may view the subject in a different light; and it will prove no small accession to our knowledge should we discover in this or in any other untried agent the power to arrest so hitherto fatal a disease as that which forms the subject of the above brief remarks."

Dr HENRY BENNETT contributes to the same journal an article on the sanitary characteristics of *Mentone*, a small Italian town at the foot of the Maritime Alps. The climate appears to be unusually warm, though cold after sundown, dry, and without fog. The Author considers the place adapted for the residence of consumptive patients. Mr HEATH contributes a case of *Excision of Diseased and Anchylosed Knee with Good Result:*

"Charles P——, aged eleven years and a half, was brought to me at the St George's and St James's Dispensary, on June 8th, 1858, with the following history. He had scarlet fever six years ago, and the left knee then became swollen, and continued so for three years; the boy being able, however, to walk about. Three years ago an abscess formed on the outside of the joint, which was opened by Mr Blagden, who applied a straight splint, and the boy was kept in bed three months, after which he was able to walk about again, the wound still discharging slightly. About twelve months ago, an abscess began to form on the inner side of the knee, and he was taken to one of the metropolitan hospitals, where he was admitted as in-patient on September 15th, 1857. The abscess burst, and another formed. The actual cautery was applied over the joint, and he was discharged at the end of April, 1858, as the parents would not consent to his undergoing amputation of the thigh.

"Both mother and child agree in saying that on admission into the hospital the knee was straight and rather stiff, but upon his coming out it had become bent to just a right angle, which is its present condition. There is an open sore on each side of the joint, and one over the middle of it, which discharge freely. The knee is firmly fixed at a right angle, and is slightly swollen. The boy suffers pain at night, but is otherwise in pretty good health, having improved since he has been at home.

"There being evidently firm anchylosis of the joint, upon careful examination under chloroform, and the probe leading to bare bone through each of the sinuses, resection of the joint was evidently the only course to be pursued; and this having been explained to the parents, they consented to its performance.

"*Operation, June* 29, 1858.—Having made an H-incision, I attempted to turn up the patella with the flap, but found that bone firmly fixed to the outer condyle, and the femur also anchylosed to the tibia. I therefore removed the whole joint in a wedge, carrying the saw immediately behind the patella and through the upper part of the tibia. As the parts did not come quite readily in apposition, I next removed a slice about half an inch thick from the femur, when the cut ends came easily together. The edges of the wound were brought together with a few stitches, and the limb was placed on a straight iron splint with a few straps and a bandage. Two small abscesses were opened during the operation, and a quantity of gelatiniform synovial membrane was removed. Some oozing took place in the evening, but was easily arrested.

"The boy, although feable, made a good recovery, the splint being removed for the first time on August 10th, when a gutta-percha one was substituted. In September, a small abscess

formed over the head of the tibia, and the limb was replaced for a few days on the iron splint, an inside splint being also adapted to it, to counteract a tendency to bow outwards.

"On October 4th the boy was sent to the Margate Infirmary, with the limb straight and in a gutta-percha splint. The sinuses below the knee continued to discharge slightly; the rest of the wound was entirely healed.

"The portion of bone removed showed erosion of the articular cartilages and thickened synovial membrane. On maceration for a short time, it appeared that the anchylosis between the patella and the condyle, and also on the inner side between the femur and tibia, was only fibrous; but on the outer side bone had been developed, as was seen on a section. The second slice of femur was found to have included the whole of the epiphysis.

"The boy returned from Margate in December, 1858, very much improved in condition. The limb was in good position, though a little bowed outwards. Two sinuses over the head of the tibia continued to discharge rather offensive matter.

"May, 1859.—Boy much improved in health, and able to get about with the help of a stick only. The two sinuses over the tibia continuing to discharge, notwithstanding the use of injections, &c., I gave him chloroform and laid them open. Found that they both led into a cavity in the tibia, which was filled with strumous material. This I gouged out and stuffed with lint. The boy made a good recovery, and soon got about again with a high boot.

"June, 1860. (Two years after the operation.)—The boy is well and strong, and gets about admirably with a high boot. There is still a sinus over the head of the tibia which discharges occasionally, but otherwise he has no trouble with it, and no pain at all. He continues to wear a gutta-percha splint, by his own desire, since I do not think it at all necessary, the anchylosis being perfectly firm. The boy does not appear to have grown much, but not having previously measured him I cannot speak with certainty. The measurements at the present time are—Height: 4 ft. 6 in. Right side: From anterior superior spine to lower end of femur, 13 in.; from the last point to inner malleolus, 10¼ in. Left side: From anterior superior spine to lower end of femur, 11 in.; from the last point to inner malleolus, 10 in. Thus the difference is exactly 2¼ in., and depends, as nearly as can be ascertained, upon a shortening of two inches of the femur and half an inch of the tibia. The heel of the boot he wears is two inches and a half in depth. The limb is not, perhaps, so perfectly straight as some that have been seen; but it must be borne in mind that the operation and treatment were conducted in a front kitchen, and under every disadvantage as to attendance, &c.

"I could have wished that, instead of a second slice of femur, I had removed a further portion of tibia, thereby possibly preventing the abscesses, &c.; but at the time of the operation the surgeon's attention had not been so forcibly called to the advisability of leaving the epiphysis of the femur as has since been the case. I shall endeavour to keep an eye upon my patient, so as to ascertain and report upon the effects of further growth."

The 'Medical Times and Gazette' contains a continuation of M. CLAUDE BERNARD'S Lectures on *Experimental Pathology*. He treats especially of the Functions of the Œsophagus and on Fistulous Apertures of the Stomach:

"The intimate anatomical relations of the pneumogastric nerves with the œsophagian tube have naturally suggested the idea of examining the physiological effects which, by dividing these nerves, are produced on the digestive functions. It has been asserted that the sensations of hunger and repletion, of emptiness and fulness of the stomach, were entirely abolished by this operation; animals are, in fact, generally averse to taking food under these circumstances; and, whenever they consent to do so, symptoms of suffocation almost immediately make their appearance. It was therefore contended that, equally incapable of perceiving the effects of abstinence, or of feeling that the wants of nature had been fully satisfied, their indifference on the one hand, and their voracity on the other, were the real causes of the accidents observed. But the experiment, in several respects, had not been properly controlled.

"Having produced a fistulous aperture in the stomach of a dog for the purpose of examining the secretion of gastric juice, I was led to divide the pneumogastric nerves, in order to ascertain whether the ingestion of food gave rise to its usual stimulating effects on the glands of the stomach, when partially deprived of nervous influence: but the aliments having been taken by the mouth, I was highly surprised not to see them appear in the stomach; they collected just above the cardia, and gradually filling up the whole length of the œsophagus, reached the upper orifice of the larynx at last, their presence in this latter region occasioning, of course, fits of suffocation. This result appears singular at first sight; for, although in a state of health the contractions of the œsophagus contribute to press food into the stomach, yet when its muscular coat is paralysed by the section of its motor nerves, how does it occur that the contractions of the pharynx do not give a sufficient impulse to the alimentary mass, which tends by its own weight to descend into the gastric cavity? The reply is, that a spasmodic contraction of the œsophagian orifice of the stomach opposes the passage of the food into its cavity, and withstands the contractions of the pharynx; but in the course of a day or two this peculiar state ceases to exist, and the animal is generally able to eat when thirty-six hours have elapsed after the operation. It is therefore evident that the section of the pneumogastric nerves exerts no influence whatever upon the sensations connected with the state of emptiness or repletion of the stomach. We shall now perform the experiment in your presence, and the results we have just been describing will be exhibited by the animal.

"(The pneumogastric nerves having been divided in a very large rabbit, the animal is presented with food, which it swallows with great voracity, having been purposely kept fasting for the previous twenty-four hours. Symptoms of suffocation are rapidly produced: the animal soon recovers, and attempts again to eat, which soon brings on another fit. At the close of the lecture the rabbit is killed and opened. The œsophagus is found entirely filled up with undigested food, from the cardia to the pharynx, while the stomach only contains some vestiges of the animal's last meal; for in the Rodentia, even when kept fasting for a certain time, the stomach is never completely empty.)

"These are not, gentlemen, the only experiments that have been tried on the œsophagus. An opening has been made on this canal for the purpose of extracting the alimentary bolus, in the state in which it makes its exit from the mouth; this experiment enables us to ascertain with what proportion of saliva it has been impregnated during mastication; by giving the animal dry food, and weighing it before and after the operation, the quantity of saliva therein contained is easily calculated; thus, when a horse is given ten grammes of straw, which has been previously dried with care, the mass extracted from the œsophagus weighs a hundred grammes; it might thence be inferred that the animal adds *nine hundred* parts of saliva to *one hundred* parts of food: the proportion, however, varies with the different descriptions of alimentary substances. When the parotidian duct has been opened on both sides, its secretion does not, of course, flow into the mouth, so that the process of mastication is more difficult and lasts a much longer time; the animal's thirst is also increased: all these results are easy to be explained, by the nature of the gland's functions, which we have just been studying in the preceding Lecture.

"The mechanism of deglutition has also been studied by means of similar experiments. When the œsophagian duct is opened in a horse, and a ligature applied under the opening, if food is given to the animal, it escapes from the aperture in small separate masses; if on the contrary, the œsophagus is divided, the aliments swallowed make their appearance in one continuous mass, the upper portion pushing out the lower parts. In other words, the power of contraction of the œsophagus is exerted in the first instance, while the impulsion is entirely derived from the pharynx in the second. The natural conclusion which we arrive at from these experiments is, that œsophagian contractions cannot be produced, when fixed points of insertion no longer exist at each end of the membranous tube; for in all other respects the conditions of the experiment are exactly the same as in the previous case, and the nerves have not been injured, as far as the upper extremity of the duct is concerned."

The Author then remarks on the importance of the experiments that have been made on the stomach of animals for the purpose of ascertaining the qualities of the gastric juice. He says that the horse and rabbit are unfit for these experiments, and that the dog is the most suitable, observing:

"To M. Blondlot belongs the honour of having been the first to conceive the idea of this operation. The following is the process invented by this able observer:—

"The animal being laid on its back and properly secured, an incision is made over the linea alba, from the xiphoid appendage down to the symphysis pubis; the stomach is then seized with a pair of forceps and drawn forwards. A silver wire is then passed into the walls of the stomach and twisted round a wooden obturater, placed outside of the abdomen. This first part of the operation having been performed, the animal is allowed to rest for a few days; and when, after a sufficient lapse of time, the walls of the stomach have adhered to the abdominal opening, the anterior surface of the organ is opened with the bistoury, and a canula is introduced.

"In my own experiments I found it more convenient to modify the *modus operandi* in the following manner:—The stomach is, in the first place, distended, by allowing the animal to feed copiously an hour or two before the operation; the incision is then made, and simultaneously comprehends the walls of the abdomen and the anterior surface of the stomach, which, being distended, is contiguous to them; the canula is then immediately introduced, and a few sutures are made, in order to connect the abdominal wound with the gastric aperture. The operation almost invariably succeeds; and within a couple of days the experiments on digestion may safely be commenced.

"M. Blondlot has lately brought before the public a modification of his own process, which enables the operator to dispense with a canula. It sometimes happens that an intense inflammation of the lips of the wound is produced, and that the presence of the instrument occasions a painful irritation, which renders it necessary to withdraw it; when this is not done, the neighbouring parts are sometimes mortified. In my own experiments I have avoided this inconvenience by using a double canula, which enables me to substitute a smaller one for the first, when too large.

"M. Blondlot adopts a different method. After having cut open the abdomen, he provokes an adhesive inflammation, which connects the anterior surface of the stomach with the lips of the wound: he then compels the animal to swallow a ball of packthread, allowing one of its extremities to hang out at the mouth. By means of a forceps he then seizes the other extremity within the gastric cavity, after having opened it; an obturator is then fastened to the anterior extremity, and the string being drawn out through the wound, the obturator passes through the œsophagus into the stomach, and occupies the aperture, which it entirely closes. In this manner the opening can be closed at will by pulling the string fastened to the obturator, and laid open again by forcing the obturator back.

"In practice this method appears to offer considerable difficulties; and we still continue, as usual, to make use of a double canula, instead of adopting M. Blondlot's new process.

"We shall now perform the operation before you, and in our next Lecture the animal on which the experiment is now made will no doubt be sufficiently recovered to furnish us with an abundant supply of gastric juice; we shall then examine successively its interesting properties, as well as that part of the digestive act which takes place within the stomach.

"(The experiment was immediately performed upon a very large and fine greyhound; the animal having fed about an hour before the operation, was of course in full digestion at the time; and as soon as the stomach was opened a large quantity of gastric juice escaped from the wound.)"

Dr Conolly continues in the same journal his *Recollections of Insanity*. We extract some passages :

"In the course of these new admissions, the primary advantage of a kind reception of the patients was a lesson soon learned. A superintendent should always visit a new patient with the least possible delay, and help to associate his kind demeanour and words with the first impressions of a time full of anxiety to a helpless person, conscious of his helplessness, and consequent dependence on those to whose care he is consigned. It was seen that the impressions made by observing this rule were seldom without their salutary influence, and seldom or never forgotten. A very general error is perceptible in too many instances in the manner in which insane persons are accosted by those about them ; who often seem to consider them insensible to the absence of civility, or even to remarks of an unfavourable nature on their malady and the habits induced by it. The young Practitioner anxious to conciliate his patients, and to acquire influence over them, should carefully avoid this fault, and always treat insane people, of whatever class, with a certain respect. They do not like to be too familiarly or even condescendingly addressed ; and their feelings are too real, and even their delusions too serious in their own estimation, to allow them to be jested with or laughed at ; and scolding them only excites their anger or detestation. There is something in madness which makes the poorest patient as sensitive in these respects as one of a superior class. A sort of refinement of feeling, one might almost call it, is in some manner associated with their malady, and for a time the conventionalists of life are subjected to a kind of equalisation. The first interview which the patient has with the Physician under whose care he is to be placed, and the first entrance into an asylum, commonly excite his facultics of observation very strongly. Every word is noted, every look is watched ; the aspect of the entrance of the house, the dress and manner of the servants, the passing view caught of other patients, all are acutely perceived, and furnish matter for suspicion and dread, or for something approaching to confidence and hope. Among the poor, and sometimes even among the rich, the distress existing in the mind is often in these circumstances increased by the bodily discomfort arising from the neglects to which they have been exposed as regards food, raiment, and personal cleanliness. A reception, kind, quiet and friendly, the administration of proper refreshment, a warm bath, the prospect of a clean and decent bed, produce so general an improvement as to place a kind superintendent or proprietor in a difficulty as to the written statement required from him by the law after two clear days of observation. Patients of the highest classes respond in some degree to these comfortable influences ; but on the poorer the effects of them are commonly striking. In the days to which my recollections chiefly refer, it may easily be supposed that taking off long-worn restraints, removing ragged and dirty dresses, and supplying the unexpected comforts of a warm bath, and a pleasant and wholsome meal, were sometimes even in their first consequences miraculous. The patients who had been brought into the asylum struggling or shrieking, heated, and flushed, and irritable, were generally found, when visited a few hours afterwards, so altered in appearance and manner as scarcely to be recognised. They had heard gentle words, long unknown to them ; they perceived, in all their trouble and confusion, that they were not uncared for, not abandoned, not perhaps in quite a hopeless state. Many happy examples of incipient amendment, followed by permanent recovery, occurred in patients whose first appearance was far from promising ; some apparently ungovernably turbulent, and some so deeply dejected as to express their belief that there would be for them, to use their own expressions, no sun, no moon, evermore. In subsequent years I have now and then met some of these patients happy and well, and been greeted by them in the crowd of London with a cordiality puzzling to the bystanders. I could fill many pages with cases illustrating these circumstances, on some of which, even after many years, and when some of the sufferers whom unexpected comfort reached this manner have been long resting in the grave, I sometimes dwell with a satisfaction no earthly events and no time can weaken or fade.

"But there were occasional difficulties to be overcome requiring repeated efforts and unwearied patience ; for among the insane of cities and of suburban villages are many whose malady has been but the close of a life of irregularity, or violence or crime, and whose habitual defiance of social order has qualified them to oppose authority of every kind, and to defy kindness as bitterly as severity. Fierce maniacal men were to be treated, who long regarded forbearance and civility with contempt, until some chord was accidentally touched to a sweeter tone, some subject allied in their wild thoughts with softer impressions, or with past events in which their better feelings had once been interested. Examples of this kind occurred chiefly among our Scotch patients, and I have known the name of Burns act upon them sometimes like a charm, and suspend what had appeared to be endless hostilities. Discharged soldiers, not often of the best class, were to be reduced, if possible, to order ; skilful in evasion, and daring in disobedience to rules. Among these the Irish were the most unwearied in troubling ; ever impulsive, crazy from the freest use of stimulants, soon recovering when compelled to temperance ; full of legal arguments for release ; rapidly relapsing when released, and now and then suddenly revengeful and dangerous. The virago, the dread of many a Middlesex hamlet, was to be managed ; whose sharp intellect endowed her with exhaustless means of mischief, and who knew peculiarly how to plague every officer, and had a nickname ready for every magistrate who fancied his position and bearing would command her respect. Wild Irish women were not uncommon, passionate and variable, alternately provoking and amusing ; but sometimes also grieving and tormenting, with almost a demoniac instinct and delight, those who were indefatigable in their service, so that the nurses would sit down and cry from vexation and despair. The destruction of clothes and furniture effected from time to time by these violent women was extraordinary ; and some were so strong, active, and ingenious, that locks, and bolts, and screws, and guards for windows, were so many toys, which they could take to pieces without any instrumental aid ; the disjointed materials being sometimes politely presented to the astonished attendants, or to the physician at his morning visit. In some of these curious cases the commencement of convalescence was characterised by a more humorous mischief. One Irishwoman whose violence had often terrified the whole staff of nurses, becoming less malignly disposed, had a particular satisfaction in sewing the dresses of the female patients to those of their nearest neighbours, as they sat together, sometimes their gowns, sometimes their cloth boots ; from which it resulted that when the one at the end of the bench moved away, the next was constrained to follow, and the next, so that they moved altogether if they moved at all. Another had particular pleasure in hiding herself, and causing a wide and general search to be made for her, sometimes including the despatch of a special messenger to one of the London workhouses, where it was thought she might be found. After one rather anxious afternoon of this kind, she emerged from a large coal-box in one of the day-rooms, on the lid of which, to her extreme delight, the nurses had sat for a time in dolorous counsel as to the steps to be taken to find her.

"Perhaps I may be unduly afraid of the possibility that at some future day, in consequence of the apparent tendency of the governing bodies of County Asylums, who are more and more pressed for the admission of pauper-lunatics, to enlarge them unreasonably, that mechanical restraint will be revived in some of those establishments and introduced into others in which it has not yet been resorted to. The size to which the asylums of Middlesex have already been extended is clearly incompatible with the exercise of such supervision as can be satisfactory to the Medical Officers ; and the consequences of various kinds will be such as to direct the thoughts of those who persist in defending unlimited augmentation of buildings for the insane to the old methods, of restraining patients in default of vigilant and unintermitting and impossible inspection. Such a lamentable reaction would not have the sanction of the Medical Officers of any asylum, nor of the Commissioners in Lunacy ; but the opinions of Physicians and the authority of Commissioners may be found as unavailing in such apparent necessity as they have been in resisting the enlargement of asylums to a point incompatible with the proper management and treatment of the patients."

Some remarks then follow on the advantages of the non-restraint system, and Dr Conolly concludes :

"Of all this the superintendent who would abolish or maintain the abolition of mechanical restraints must preserve a firm and earnest conviction, not to be shaken by the misgivings of those whose indolence or indifference makes them insensible to the state of the poor lunatic, whose life is literally in his hands. We can believe in the intensity of feeling which agitated Samuel Tuke, when the struggle had begun at York, more than sixty years since, and which wrung from the good and quiet quaker's heart that earnest prayer recorded in his journal,—"Teach Thou my hands to war and my fingers to fight for these my defenceless and injured fellow-creatures, for Thou alone art the fountain of knowledge, wisdom, and strength." Difficulties, trials, and even griefs may be incurred for a time by all engaged in such a task : few important improvements are effected without these drawbacks, inseparable from all tasks assigned to this mortal state ; but the real, and striking, and happy results on the patients will soon afford encouragements more powerful than them all. Such must have been the experience, such the trials, of Mr Gardiner Hill, at Lincoln ; of Mr Gaskell, at Lancaster ; of the late Dr Hutcheson, at Glasgow ; and of the late Dr Anderson, at Haslar. Their labours have not been fruitless ; and when they were completed, the question of non-restraint was decided, and as respects the insane, the battle of humanity was fought and won."

Mr Buxton Shillitoe describes in the same journal a *New Form of Catheter* for dilating strictures. The form of the catheter recommended is that of a short cone, commencing about one inch and a quarter from the end.

Dr Elliotson contributes to the 'Medical Times and Gazette' of June 30, a paper on *Urethral Rheumatism and Ophthalmia*, which we quote.

"My first knowledge of the occurrence of the disease was obtained from Sir Astley Cooper's lectures, which I attended at St. Thomas's Hospital in 1806-7 and 1807-8. How many years previous he had mentioned or seen it I cannot say. He pretended to no merit of discovery, but related in the most artless manner the communication of the facts to him by a patient. 'An American gentleman,' he said, 'came to me with the clap, and I told him he might think himself well off to be so little affected.' 'Oh,' said he, 'a clap with me is a serious thing. When I had it before, I was attacked a few days after the infection with an obstinate inflammation of the eyes that was followed by rheumatism.' 'I thought,' continued Sir Astley, 'that he might have caught cold while taking mercury, but he said he had taken none. I therefore watched the disease ; and in a few days his eyes became inflamed ; and after that one of his knees swelled, and then the other became affected with chronic inflammation. He was attended by Dr Relph, of Guy's Hospital, and myself for many months. He left this country uncured, but I heard that he got well on his voyage. Since this case I have seen many more such.

"It is very natural to suppose, before our experience became enlarged, that the disease was the result of gonorrhœal contagion : and the appellation gonorrhœal rheumatism, given naturally to it from its alliance with gonorrhœa, must have increased the tendency to this view. We cannot wonder, therefore, at Sir Astley Cooper believing that the ophthalmia was produced, not indeed by the application of gonorrhœal secretion accidentally to the eye, as may happen with any careless patient, but still by the absorption of it into the system, and that the proper treatment of the rheumatism, produced to his view of course by the same poison, was the same as of gonorrhœa — half-a-drachm, according to him, gradually increased to a drachm, of copaiba, with spirits of

turpentine, three times a day. We have no specific remedy for gonorrhœa, any more than for measles, scarlatina, or small-pox: and those drugs must in many cases aggravate gonorrhœa: and they would aggravate many cases of the rheumatism. Copaiba, cubebs, and some analogous drugs, are useful occasionally in gonorrhœa, but not more so than in similar uncontagious affections of the genital passages, and possibly of some other mucous membranes. If there is no reason to ascribe specific powers over gonorrhœa to them, neither is there any to conceive that they can be remedies of the rheumatism bearing the distinction of gonorrhœal. Nor are they (*a*).

"The belief, now generally prevalent, of the rheumatism in question — rheumatism with urethral discharge—and indeed of the ophthalmia, being really the product of gonorrhœal poison, is, I am satisfied, as unfounded as the previous generally prevalent disbelief that rheumatism and ophthalmia are ever connected with gonorrhœa. It was long before this struck me: for I had always read of those forms of disease, and heard them spoken of, with the epithet gonorrhœal: and had not seen them except in gonorrhœal patients. After a time I received the assurance of one or two patients that the affection of their genitals could not have arisen from infection: but it made no impression upon me, because I am familiar with the untruths which are often told upon these subjects, and because patients do really sometimes fondly deceive themselves as to the character of those with whom they intrigue. But, as years passed on, more instances of the alleged impossibility of infection presented themselves to me: and some such patients, I felt certain, could have no reason to deceive me, were too much endowed with self-respect to stoop to an untruth, and were too acute to be themselves in error. Some have told me this long afterwards, when they had ceased to incur the possibility of catching any disease of the genital organs. I knew no one inclined to this view till five years ago, when, accidentally meeting with a surgeon, a married man and a father, who had consulted Sir Astley Cooper and myself twenty years at least previously for what we had all termed gonorrhœal rheumatism, and since which time I had not heard of him, I was told by him that, before he married, he had again suffered a few attacks of rheumatism and urethral discharge, on which occasions the idea of infection was altogether out of the question, as he had not been exposed to the possibility of risk. At this period he had no inducement to deceive me as to his former life; and formerly he had always been candid when suffering for irregularities. He added that since his marriage he had occasionally suffered in the same twofold manner as when he was irregular and single. I was much pleased, and I communicated to him that my convictions of these affections being improperly termed gonorrhœal was as strong as his own. Farther experience up to the present moment has set the question completely at rest in my mind. Indeed, although the circumstance is not noticed by the Profession, some writers clearly entertain this opinion and state facts which establish it, and yet lay no stress upon its difference from the commonly-received views. I have just found that Sir Benjamin Brodie, in his 'Pathological and Surgical Observations on Diseases of the Joints,' published in London in 1818, gives five cases of the disease witnessed by himself, and remarks that in one the patient could not ascribe the discharge to infection, and in another the patient suffered from strictures in the urethra, and, although rheumatism took place twice with gonorrhœa, it took place twice also when there was no gonorrhœa, but the urethra was in a state of irritation and discharge through the mere introduction of bougies employed on account of the strictures. He, therefore, says that it may occur without infection. Brandes also considers that the rheumatism may be re-excited after all gonorrhœa has ceased, if the urethra is irritated by any common cause: and speaks of this rheumatism as *blenorrhagique* (gonorrhœal), and *traumatique* (such as from the introduction of a foreign body into the urethra). Marechal gives a case of rheumatism, long and with all the other characters of gonorrhœal rheumatism, that had followed an urethral discharge produced by nothing but the immoderate use of new beer, and such as had never occurred in the man before.

"My own experience, extending through so many years, renders it impossible for me to doubt that specific and contagious nature is unnecessary to the urethral irritation which in certain persons gives rise to rheumatism and to ophthalmia also in others—that the mere irritation is sufficient, and, in fact, is the cause, and that the gonorrhœal, contagious character is incidental only. The combination of the cases of other writers with my own will, I hope, settle the question. The single case of syphilitic infection of a lady by secondary symptoms in the hand of her maid, recorded by me in the 'Medical Times' of Sept. 4, 1858, removed all possibility of farther doubt respecting the occurrence of infection from secondary sores. The determination of the production of rheumatism by simple urethral irritation is effected by the repeated experience of many of us continued through a large number of years. The impediment to the perfect knowledge of what is known as gonorrhœal rheumatism was its extremely rare occurrence among the instances of rheumatism at large, on account of the comparatively small number of persons affected with irritation of the urethra, and the still smaller number of persons among these that have the unfortunate peculiarity of liability to rheumatism from it. The impediment to the knowledge of simple irritation of the urethra being the cause was still greater, on account both of the great rarity of simple, compared with gonorrhœal, irritation of the urethra, and of very few individuals indeed being the subjects of both simple urethral irritation and liability to rheumatism from irritation of the urethra. Those who from habit regard this kind of rheumatism and ophthalmia when allied with gonorrhœa as therefore gonorrhœal, must remember that in every case of gonorrhœa there are two circumstances united—the irritation of the urethra and the specific nature; and that the latter cannot exist without the former, although the former may exist without the latter. Consequently, no case of gonorrhœal rheumatism or ophthalmia proves that the rheumatism or ophthalmia depends upon the specific—the gonorrhœal—nature of the urethral affection, and not upon the irritation irrespective of specific nature.

"A little experience of this rheumatism impressed me, as it has done many others, with certain characteristics, and I detailed them in clinical lectures above twenty years ago. 1. I saw and see it so frequently in the feet, that whenever a rheumatic man has walked into my library lame from rheumatism of his feet, I have startled him with the question how long he had been suffering under gonorrhœa. It not unfrequently affects the hands—perhaps, as I once saw, a single joint only; the wrists and elbows; but the lower extremities most frequently, the knees as well as the feet; the hips also. It may affect any joints, and several at one time or in succession; the loins also and back of the neck. I saw it once in the joint of the jaw. 2. Its obstinacy and extreme duration are remarkable. The longest case I ever saw was in the jaw, and after two or three attacks imperfect rigidity, I believe, became permanent. 3. I am not aware of ever having seen it in a female. But gonorrhœa is comparatively rare in women, as one loose female contaminates scores of men, and, however great the number of loose women, the number of men who have been occasionally loose is almost equal to the number of all men. 4. But the most important and perhaps an invariable point in its character is its inflammatory nature at first, and for a very considerable time. This struck me before I had seen many instances of the disease, and I did not find that it had been noticed. But Sir Benjamin Brodie, whose book upon diseases of the joints I had never seen, had possibly made the same remark; for previously, in fact above twelve years before I was aware of witnessing the disease, he had written that colchicum was the best remedy for it; and the great utility of this medicine against rheumatism I believe to be in the inflammatory form. Not only is the disease, but its inflammatory nature, disposed to continue very long. Yet at length—after a long period—the time may arrive when the iodide of potassium, tonics, and general and topical stimulants, are the suitable means: and forcible extension of the joint may be proper. Till that time arrives, the treatment should consist of patient abstinence from fermented and distilled liquids and flesh food, the removal of external stimulants, rest, and a position which favours the presence of as little blood as possible in the affected part or parts, the discrete use of colchicum and other purgatives, and the repeated application of leeches. The same kind of treatment is suitable to the ophthalmia, which, however, is seldom so obstinate. I believe that the rheumatism occurs in general earlier than the ophthalmia; it often occurs alone; and there may be differences in these two particulars in the same individual in different attacks. 5. These two affections bear no relation to the intensity of the urethral. The smallest discharge will produce the rheumatism, and perhaps the ophthalmia likewise, in the predisposed; nor is the intensity or duration of these in proportion to the degree of the urethral; and they, or one of them, may continue after the urethral. 6. I have known several persons suffer from gonorrhœa more than once without either of these consequences, and then become subject to them; but only one individual escape an attack of rheumatism after every occurrence of gonorrhœa when once rheumatism had followed the appearance of urethral discharge. I have seen the predisposition to this urethral rheumatism in several men of the same family, whether the irritated state of the urethra was gonorrhœal or not.

"The predisposition is a great misfortune; because, as soon as the urethral affection begins, the patient feels certain of an attack of chronic rheumatism: and, though it may take place in a few days, it may not for a considerable time, but is sure to come: and the mildness of the urethral affection does not foretell a mild attack."

The 'Dublin Hospital Gazette' contains a Report of a *Case of Obscure Aneurism of the Aorta*, occurring in St. Vincent's Hospital, under the care of Dr O'Ferrall:

"The post-mortem appearances were submitted to the Pathological Society by Dr Stokes, who, in bringing it before the Society, said that he did so as one of the Secretaries of the Society, on the part of Dr O'Ferrall, who was unable to attend. Dr Stokes said—

"The case was one of aneurism of a portion of the aorta, and had some important and interesting features in connection with the diagnosis of that disease. The subject was a man aged thirty-six years. From his earlier manhood he had been of dissipated habits, and had led a reckless and intemperate life. He enlisted, and had been sent with his regiment to India; whilst in that country his health gave way. He became affected with cough and pain in the left side. Being found unfit for duty, he was invalided and sent home; and shortly after his arrival in this country he was received as an intern patient into St Vincent's Hospital, in February last, under the care of Dr O'Ferrall. At the time of his admission, he was labouring under severe dyspnœ and a distressing cough, which seemed of a spasmodic character, and attacked him at intervals. During the paroxysms, which were violent, the cough was characterized by a peculiar ringing, and, as it were, metallic sound. The expectoration was scanty. This man complained, especially after an attack of the cough, of sharp, lancinating pains in the region of the right mamma, shooting from thence towards the axilla.

(*a*) For thirty years I have not prescribed copaiba, cubebs, or any special drug in gonorrhœa, but contented myself with ordinary antiphlogistic measures as long as inflammation existed and for some time afterwards, and my practice has been most successful. But then I fully carry out the plan, allowing no fermented or distilled fluid whatever, nor any other stimulating substance; and enjoining the utmost rest of the legs that is possible, as well as abstinence from flesh food, even in the form of broth. In addition, mild aperients, abundant diluents, the application of warm water, a constant suspensory to prevent orchitis, narcotics when indicated by chordee, make up by far the most satisfactory treatment that I ever adopted. I know that copaiba, cubebs, and injections, sometimes arrest uninflammatory and even obstinate gonorrhœa; but perseverance with the plan which I have mentioned, above all with the negative part of it, is almost always sufficient, and is the best preventive of, as well as a most important remedy in, strictures and all inflammatory irritations of the urethra and the rectum. The importance of perfect abstinence from stimulating drinks and from flesh in toxic inflammations is by many not duly appreciated.

Decubitus was generally and by preference on the right side. The man was much emaciated. His countenance was of a sallow paleness, and bore traces of great suffering.

"On examining this patient, Dr O'Ferrall found that the entire surface of the thoracic region, on its left posterior aspect, sounded dull on percussion; muscular movement on the same side was very limited. On measurement of the thorax, no remarkable difference was perceptible between the bulk of its right and left sections respectively. The heart was found slightly out of its normal position, and towards the right side. On careful auscultation no murmur could be detected along the course of the aorta, or, indeed, within the chest at all. Neither could any decided râle be recognised. In the region of the left side of the chest posteriorly, tubular breathing could be distinguished. There were faint vocal fremitus and bronchophony. It was remarkable that there was not the slightest indication of the bellows murmur, either in the region of the heart or along the course of the great vessels, at any stage of this case. There was no dysphagia (although, as it afterwards appeared, nothing would have been more likely to occur under the circumstances). There was no laryngeal stridor. There was no tumefaction above the clavicles. No inordinate cervical pulsations. The respirations ranged from thirty to thirty-eight in the minute. The radial pulse (equal at both wrists) averaged about one hundred. There was no new centre of pulsation established in any part of the chest. There was, in fact, a complete absence of the ordinary symptoms of aortic aneurisms, the absence of anything like murmur being not the least remarkable. Notwithstanding these symptoms, or rather despite of the absence of the indications ordinarily relied on, Dr O'Ferrall unhesitatingly formed his diagnosis of the case, which was, that the left bronchial tube was pressed upon by an intra-thoracic tumour, and, moreover, that that tumour was an aneurism of the aorta. Dr O'Ferrall asserted and maintained this opinion despite of the absence of the ordinarily received rational symptoms of arterial lesion in the chest, and he observed that he was principally sustained and fortified in his opinion by, *firstly*, the fact of the lancinating and darting pains experienced by the patient, shooting from the mammary region towards the axilla; and *secondly*, by the peculiar character of the hard and ringing cough. It was true that analogous symptoms might be produced by an intra-thoracic tumour, not aneurismal—a carcinomatous tumour, for instance; but on reviewing the other symptoms and constitutional condition of this man, Dr O'Ferrall found reason from his own practical experience to adopt and adhere to the conclusion that the disease was aneurismal. The progress of the disease was watched with great care and attention. Eventually the man died suddenly after having ejected a small quantity of blood from the mouth.

"*Post-mortem.*—On laying open the thorax, the left lung was found to be in a state of pneumonic solidity. It should be observed that this man had been in an advanced stage of pneumonia at the time of his admission into hospital. A large aneurism was found occupying the transverse portion of the aorta. The aneurismal sac opened by two perforations into the left bronchial tube, against which the aneurismal tumour, previous to its bursting, must have pressed severely. This was really a false aneurism in the truest acceptation of the term, and this fact rendered more strange the absence of all ordinary indications of its presence during life. In cases of what was termed true aneurism it was not unusual to find the symptoms obscure and ill-defined; but, in cases like the present, the leading indications were generally found sufficiently marked and evident.

"It was truly singular that there had been no symptom of *dysphagia* in this case; for here was the tumour reflected, and bent over the œsophagus. It was not possible but that there must have been some mechanical obstruction experienced in the act of deglutition; yet the man had never complained of any uneasiness of that kind. It would be seen that the margins of the two perforated apertures from the sac into the bronchial tube were edged with fungoid growth. This growth would seem to have become deposited in proportion as the intervening tissues of the aneurismal sac and of the bronchial tube became absorbed by pressure and likely to give way, as if there had been an effort of nature to retard the fatal bursting of the tumour.

"Dr Stokes here exhibited the preparation, pointed out the site of the aneurism, and showed the two apertures whereby the contents of the sac had burst into the left bronchus, causing immediate death."

We quote from the same journal the following remarks, also by Dr O'Ferrall, on the *Use of Larch-Bark in Hæmorrhages*:

"There is no accident which occasions more anxiety to the physician, as well as to the patient or his friends, than internal hæmorrhage, and none that from its suddenness and danger renders empirical treatment more justifiable. In such a case time is everything; life is ebbing away, and we cannot wait for the development of the physiological effects of medicines, the principle of whose action we fancy we understand. There is no occasion therefore in which we require to be provided with so many expedients in the event of failure of those we have already tried. When a new styptic is proposed, it becomes the duty of the clinical physician to avail himself of the opportunities afforded by a large hospital, and to record as early as is consistent with accuracy the results of his experience. The larch-bark has been proposed as a remedy in purpura, and analogy naturally suggested it as a means of controlling similar conditions of the mucous membranes, often of an alarming nature. The first class of cases in which I directed its employment was the intercurrent hæmoptysis of phthisis; in some of those, the usual remedies—ipecacuanha, lead, tannic or gallic acids, &c.—had been employed without effect, when the larch-bark was tried. The hæmorrhage became diminished and soon ceased, and the remedy rapidly began to acquire an importance in our estimation. As confidence in the drug increased, it took an early place in the prescriptions for such cases, and up to the present moment has given such satisfaction, that it is the prevailing remedy in my wards for this affection.

"There is another class of cases, often of an exceedingly obstinate nature, in which it has proved of signal service—cases of uterine hæmorrhage. Some of those cases have depended upon the presence of fibrous tumours connected with the uterus; others upon carcinomatous degeneration of the organ. In both the use of larch-bark has been followed by a cessation of this dangerous accident. In some cases of hæmaturia from various sources—renal or vesical—the blood in the urine disappeared under its use.

"In hæmatemesis I have not yet ventured to try this medicine, as I have not experienced failure from the ordinary remedies—turpentine, gallic acid, &c.—since its introduction.

"The form in which I am in the habit of exhibiting the larch-bark is that of the tincture, in doses of half a drachm every third hour."

OUR NOTE BOOK.

HYDROCEPHALUS.

In the March number of the 'New Orleans Medical News and Hospital Gazette,' Dr Marsh, of Port Hudson, reports a very interesting case of hydrocephalus, in which *paracentesis capitis* was several times performed. At the time of the first operation the patient was about nine months old. "Its body and extremities were emaciated beyond the power of pen to describe. It seemed as though there were nothing but integuments, bloodvessels, and bones left. At the same time, it had the face of an infant, and the head of a man." The head measured 26 inches in its longest diameter. At the first operation "eleven ounces of fluid were drawn off, clear and pellucid at first, and of a slightly saline taste, like perspiration, but turbid at last." Sixteen days later the second operation was performed, and *sixty-four* ounces were evacuated, "with a very strong smell of urine." Eleven days later sixteen ounces of fluid were withdrawn, and three days later the patient died. Dr Marsh says, "It may be proper here to observe, that at no time after an operation could the bones of the head be compressed so as not to leave a cavity between them and the brain. As the water again accumulated, it could be distinctly heard surging from one side to another, as the child was moved."—'American Medical Monthly.'

HÆMATURIA.

In the 'Medical and Surgical Reporter' for March 3rd, Dr E. T. Blackwell reports a case of hæmaturia, which full doses of gallic acid, opium, &c., failed to relieve. He says, "Finding the remedies entirely fail, I ordered the bladder to be injected with a weak solution of alum, at first tepid, afterwards entirely cold. The effect was happy and rapid."—'American Medical Monthly.'

CURE OF FALSE JOINTS.

The Academy of Sciences has been fortunate enough to receive, at a few days' interval, two communications relative to false joints cured by different modes of operation. Our readers will find at the Art. *Learned Societies* the summary of an interesting paper, by M. Jordan, on autoplatsy of the periosteum applied to the treatment of pseudarthrosis. This method consists in the oblique resection of the two fragments, at the extremities of which the periosteum has been previously detached for the purpose of preserving a double ridge for the reproduction of the osseous structure. This method has been known for several years, but it seemed rather adapted to theory than to clinical practice. If it were even easy to apply the process in the operating-room on healthy bone, it seemed very difficult, not to say impossible, to obtain a satisfactory result with bones enveloped with irregular stalactites. M. Jordan, however, was not stopped by this difficulty, and in the case of pseudarthrosis recorded in his memoir, he was enabled to obtain the consolidation of the tibia by inserting the lower fragment into a cap dissected from the superior fragment.

In an analogous case, M. Jobert de Lamballe used with much success a seton, taking care, however, to excite the periostic membrane only, a process different from that hitherto pursued by the Surgeon of the Hôtel-Dieu, whose object it was to promote granulation of the osseous surfaces after after having induced superficial necrosis. The case read by M. Jobert to the Academy was that of a Tuscan commercial traveller, aged 45. This man had never experienced any serious disease, and presented no symptom of confirmed syphilis. In the month of June 1856, his right leg was fractured in a fall from a carriage. The injury of the bone was complicated by a wound of the integument, overlapping of the fragments and inflammatory congestion. For six weeks the leg was kept in Scultet's apparatus, and the following month in a plaster bandage; after three months' treatment, the mobility of the fragments persisting to the same degree, the patient placed himself under the care of M. Scutin. This surgeon had recourse to his ingenious starch bandages, in which an aperture, on a level with the false articulation, admitted of the wound being painted every day with tincture of iodine. This new treatment, protracted for two months, was not, however, more successful than the means of contention previously used, and it was then the patient decided on repairing to Paris. M. Jobert found considerable mobility coinciding with a deep groove in the tibia, a little above the lower third of the bone. It immediately occurred to him to use the seton as a means of excitement of the periosteum, and he proceeded to the operation in the following manner:

A small incision was made on a level with the line of separation of the fragments, *i. e.* on the outer and inner sides of the false joint and extending above the fracture. An iron grooved conductor was inserted between the fragments, and passed from one wound to the other without much difficulty by a to and fro movement. A style bearing a seton, guided by the groove of the conductor, soon occupied the place of the latter. Simple cerate dressings were then applied to each wound, and lint steeped in cold water was laid over the surface. This operation was performed on the 17th January, 1857. On the 20th abundant suppuration escaped from both orifices; no fever or pain was observed. The seton, after having been each day moved in a certain portion of the passage, was withdrawn on the tenth day. On the 16th the suppuration had ceased. On the 12th February the mobility had already much diminished, and on the 20th it was no longer perceptible. The 2nd April the patient was able to make use of his limb, to stand, and even walk a

few steps. At present his state is most satisfactory.

The promptitude of the cure in this remarkable case is explained by the choice of the procedure adopted by M. Jobert. Formerly surgeons obtained but a secondary callus, the formation of which required several months; in the present instance, the callus was formed at once under the influence of mechanical irritation of the periosteum, without exfoliation or previous necrosis. Cicatrization immediately ensued, and M. Flourens's theory on the regeneration of bones by their enveloping membrane has thus received one more brilliant illustration.—'Journal of Practical Medicine and Surgery.'

INJURIES OF THE SKULL.

In the 'Louisville Medical Journal' for March, Prof. Middleton Goldsmith has an article upon the 'Treatment of Injuries of the Skull,' in which he proposes a substitute for the trephine. It is an objectionable feature of the trephine that so much sound bone is necessarily sacrificed. To obviate this objection, Prof. Goldsmith has, for the last ten years, used the "chisel in place of the former instrument." He says, "With a chisel, impelled by the hand, or small hammer, just so much bone may be removed as is necessary for the insertion of the elevator, or for the extraction of the detached pieces, and no more. The dura mater is not endangered in the operation, for the depressed bone protects it. It is never necessary to cut any part of the internal table.; for if the opening in the external table is as large as the fracture of the internal table, then the external opening is large enough to allow the required extraction." To our mind, the chisel or gouge seems to possess such manifest advantages, that the only wonder is, that it had not long since suggested itself, and ere this entirely superseded the trephine. Economy in the loss of skull bone is not a matter of trifling consideration.

Dr Goldsmith says further, "In the next place, the writer has uniformly practised the immediate and perfect closure of the wound in the scalp." He believes "that the safety of the patient is vested more in the exclusion of the atmosphere from contact with the dura mater than in any other thing, and in any other circumstance in the whole operation of trephining." . . . Where there is no scalp wound, or when the latter is small, then the surgeon should make a semicircular flap, large enough to embrace the breach of bone, and to extend from one-half to three-quarters of an inch beyond it." . . . "The incision should have no angles over the breach of the bone."

Dr Goldsmith says he has operated for fracture of the skull, as above, more than twenty times during the last ten years, without losing a single case; and his colleague, Professor Hardin, has operated seven or eight times also, without losing a case. This is certainly unprecedented success, and is, doubtless, in some measure related, as an effect, to the manner of operating and dressing the wound.

BRITISH ASSOCIATION AT OXFORD.

The Association held its concluding meeting a week since, when everybody wished the "Revivalists" and the Museum folk God speed in their good work of giving new life to medical and physiological studies at Oxford—a Hercules work in a new Augean imbroglio, of which we think a few words would be valuable just at present.

The recent revival of the physical sciences at Oxford is, indeed, not without a certain gratifying interest for medical men. The age of Oxford as a seat of physical or "secular" learning is something miraculous. In the buttery at Christ Church one gets a glass of superb pale ale, brewed last week; and they will show you a gridiron belonging to Cardinal Wolsey, and shrines and pictures and pantries belonging, once on a time, to an excellent lady, a daughter of an Oxford alderman, a small matter of 1200 years old! Oxford University itself, thus old, is comparatively poor; but the nineteen modern colleges outside are very rich, due to the patronage of this exemplary Miss Frideswide, the alderman's daughter aforesaid. The property of the colleges available for education is now worth 150,000*l.* a year, which had gradually been swallowed up in a set of sinecures, till Parliament recently overhauled the matter. The Linacre Professorship in Medicine is one of the things got back from the sinecurists, who have been almost as unconscionable, on a large scale, according to Dr Acland and Mr Gladstone, as if they were our own College of Surgeons voting in its own examiners and council. Locke is, perhaps, the man that Oxford is proudest of. We, the doctors, must ever venerate the cradle where Boyle and Harvey, and Sydenham and Radcliffe, were nursed. There are other men, too, of minor note—Brown of the 'Religio Medici,' and Burton ("pancis notus paucioribus ignotus cui vitam dedit Melancholiâ"). Little, poking Pembroke College one esteems, too, as here Dr Johnson entered in his nineteenth year, and, probably, invited Goldsmith to join him in his seventeen cups of tea. Boyle is the man, perhaps, now least known of those already mentioned. He was a curious combination; he was as perfect in classic literature, apparently, as Max Müller or Gladstone, and, in physical science, as Faraday or Davy. Sir Isaac Newton admits, in his letters, he would never have gone on with the 'Principia,' but for Boyle's encouragement and aid. This was about 200 years ago. Boyle, too, founded the "Royal Society," and spent one of his summer vacations at Florence with Galileo.

Oxford has no reason to be ashamed of her science men; but there seems to be a gradual dying out of science at Oxford after the time that Harvey and Boyle lived—the well-known time that Harvey showed Charles II. the valves of the heart, and Boyle invented and discussed on the air-pump. It is a curious historical circumstance, but true, that the origin of the College system at Oxford, as well as at Paris, was due to an effort for the spread of secular or scientific learning, not ecclesiastical; but at Oxford there has always been a tendency to swallow up the former in the latter. Need we mention the well-known story of Merton or New College, told a year or two ago in Parliament by Lord John Russell? Walter de Merton endowed at Oxford a college for the maintenance of twenty boys each year, like our Bluecoat boys, who, in hobnail shoes, were to till and cultivate the College property, and, like Mr Mechi, learn agriculture and other secular sciences. William of Wyckham endowed another college next door over the way of a like kind, the senior pupil of which was to be a model of agricultural industry, plainness, and secular science. How times are changed! Two-thirds of these 542 fellows or scholars of colleges do not now reside at all at Oxford. What were originally eleemosynary foundations of about 20*l.* each have increased wonderfully in value to 400*l.* or 500*l.* a year each, and on the curt maxim, possibly, of charity beginning at home, now all is changed into rich fellowships amongst absentees, beneficed clergymen, barristers, masters of schools, bishops, &c. &c. The science of Boyle, or Harvey, or Merton, has long ago gone to the dogs. William of Wyckham's senior pupil, the expected model of industry, hobnailed shoes, and secular science, is a standing joke, as he drives his magnificent carriage and pair. Many of the men in the Church have never been at Oxford but once, perhaps, in their lives; yet all this money, Parliament decided a year or two ago, was intended for purely secular studies and physical science. These men thus educated were to be the tutors, or "grinders," if you will, to the University, in general science, chemistry, mathematics, physics, &c. Linacre, Radcliffe, Tomlins, even Buckland, in our own day did wonders to encourage this honest intention of the original founders being carried out; but it has been of little use. At Magdalen, in place of half-a-dozen Sydenhams, Linacres, or Bucklands, or Boyles, the chief men have been Gibbon the historian, Hoylyn, Addison, Fox, Collins, and forty-two bishops, all their pictures on the walls. The present writer has no objection to bishops in their right place; but one would rather they did not push the medical men and science men, like those first mentioned, out of the way. We have ourselves, however, and, peradventure, our own colleges, like that in Pallmall and Lincoln's-inn fields, to blame for it.

The new Museum at Oxford, something like our College of Surgeons' Museum of the great John Hunter, has been got up within a year or two, together with the new Linacre Professorship of 800*l.* a year, out of some of this—excuse the vulgarity of the term *pro hâc vice*—this plunder of the old colleges. We owe this reform to Lord John Russell, to whom be all honour for bringing it before Parliament, in opposition to our Medical colleges. Our individual impression is, that Oxford will never be a great Anatomical or Medical school; but the idea of Dr Acland, laid before Parliament, is a most excellent one, and was never so true and valuable as at the present moment. Dr Acland says—As one of the future "schedule" requirements for the "college and hall," let the FIRST YEAR for all students be physical science (not anatomy); the two other years, physiological, anatomical, and other studies. By general or physical science, he means that he would leave it a good deal to the student's own bent or inclination; but it might be a ticket in chemistry, electricity, geology, or botany, but notably either the first or the last the first year; and these could be best learned near the student's home, whether Newcastle, Durham, Cambridge, Liverpool, Oxford, &c. What is the state of things at present? We know as a fact that students enter now as surgical dressers, clinical clerks, &c., in shoals at St Bartholomew's, Guy's, St Thomas's, St George's, "King's," or the London Hospital—in fact, at every large surgical hospital in London—utterly innocent of the A B C of chemistry and pharmacy. One sees these poor young men constantly writing prescriptions for luckless patients, for hydrocyanic acid, emetic tartar, morphia, &c., in a mechanical manner, as if they were "bole armenack," decoction of sarsaparilla, or poppy-heads, that might be ordered by the saucerful or gallon; they have not a shadow of a thought what an acid is, or an alkali, an alkaloid or an incompatible; they laugh at the "rot" (that is the word), that people advise about apothecaries' drugs and fudge of that sort. If their rubbishy doses disagree with the mystified patient, they double or treble them as they like. Dozens or hundreds of these young men are now hanging about the hospitals prescribing, or dressing, or "clerking," having passed the first or anatomical examination at the College. Caring nothing for the "matter of form," they expect the second or pass examination to be on pathological surgery; idling the most precious half-years of their life, and putting off chemistry, pharmacy, botany, &c., they have placed the cart before the horse; in fact, they have neglected Dr Acland's precaution, or rather, in its eagerness for old routine, the College has done so for them. Everything Dr Carpenter's Burlington Arcade University boasts itself pedantically on doing for them three years hence, when they ought to have left London, Oxford or Cambridge could, would, and should have done for them, cheaper and more respectably, two years ago, when they began their anatomy and dresserships, and when chemistry and pharmacy would have been truly valuable to them. Oxford revivalism seeks to correct these blunders and abuses.

The Association held its final meeting a week since (July 4). The Secretary read a report, and said 1,390*l.* had been voted for scientific purposes, and an increase of 400 visitors over the 1,400 at the previous meeting, in the pre-museum period—shall we call it?—of Oxford had taken place. The poor Dean of Christ Church wound up the proceedings by a speech, in which he expressed a hope that by the time another meeting shall have been held at Oxford, the defects in the Oxford system, as regards physical science, the close fellowships and examinerships, whereof Lord Wrottesley had complained (close fellowships so like those of the London College of Surgeons, and appointments such as that of Mr Arnott, by the college bedel, in that day's 'Times'), would be all done away with. Oxford Examinerships and Fellowships should be thrown open to general competition, and a reign of common sense and common propriety be inaugurated! Men who know Oxford and London are, however, not so sanguine as the old Dean. The improvement will be of slow growth indeed; for with Mr Greene and Mr Arnott, Mr Lawrence, and a few others of the old-world men in power in the Educational Council, there is not a chance for the common sense of Dr Acland getting a hearing. Even in the Army Medical Board examinations, where the good sense of Sir Andrew Smith had tinkered up the best kind of practitioner he could, as army assistant-surgeon, half apothecary, half surgeon, to take care of the bottles and pill masses of his garrison hospital, as is the custom of the army assistant-surgeon, one of the last acts of the "Council" has been, as regards the Dublin apothecary "ticket" on the schedule for army assistant-surgeon, at the wise suggestion of Mr Lawrence, who himself despises and knows nothing of pharmacy, to do away with the good work of Sir Andrew Smith, as hitherto we have all opposed the Oxford revivals and Dr Acland's good work of a like kind.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B — The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, JULY 11, 1860.

THE DUBLIN COW-POCK INSTITUTION.

The ways of Government are passing strange, and continually remind us of the saying of Chancellor Oxenstiern as to the small amount of wisdom necessary to statesmanship. Our Government has professed an anxious desire to extend as widely as possible the blessings of vaccination, and Mr Simon, as its organ, has described in graphic language the horrors of a community unprotected from the ravages of small-pox. Nevertheless, with a singular retroverted logic characteristic of itself, the Government has obstinately persisted in a refusal to give the public vaccinators more than eighteen pence a case, vainly hoping that a parsimonious remuneration would prove a powerful incentive to the fulfilment of its benevolent object. The Government seems to think that the less an Englishman is paid for a case, the more strenuously will he labour to increase the aggregate of his return by multiplying the number of his cases; an ingenious Machiavellian kind of logic, highly satisfactory, perhaps, to the economical understandings of statesmen, but very repugnant to the unsophisticated notions of work-a-day vaccinators. The Government, finding on trial that this system does not quite answer, has with equal wisdom supplemented its liberality to the Doctors with a fine upon the public, and by the help of these two financial thumbscrews it hopes to secure a general obedience to its edicts. Such is the system in this country.

In Ireland matters are in a very different position—and, we are sorry to add, a worse one. A pamphlet has been recently published by Dr Long, exposing the defects of the Dublin Cow-pock Institution; and certainly we are astonished to find that any institution under Government patronage, and supported by its contributions, could be conducted with such an absence of regard for the public interests.

Our readers know that small-pox is a prevalent disease in Ireland, and that for many years there has been but a trifling abatement its virulence in that country. We find that in the decade from 1831 to 1841, the number of deaths from this fell malady were 58,006, the population being 7,039,659; whilst in the next decade the deaths were 38,275, the population being reduced to 5,334,829. This mortality is three times that of England. In short, the deaths from small-pox in Ireland are still one-half of the average rate of mortality when small-pox was allowed to run its course uninterrupted by prophylactic measures.

This is a subject in which Englishmen as well as Irishmen should feel a deep interest, for, owing to the free and rapid communication between the two countries, the liability to infection is kept up in both alike; for not only may there be, and frequently is, a direct importation of the malady into England, but, in consequence of the infusion into the mass of our population of a large number of unprotected persons, the entire community i rendered constantly obnoxious to outbursts of this dreadful scourge. What, then, ought the Government to do to repress small-pox in Ireland? We will show what it has done—or, at least, what is now done under Government patronage.

After the introduction of vaccination by Jenner, a certain number of gentlemen established the Dublin Cow-pock Institution, and, as a mode of getting funds to work it, charged half-a-crown for each "packet of infection," containing two points. By-and-by the Government took the Institution under its patronage, and contributed to it annual donations, which now amount to the sum of four hundred pounds a year: nevertheless, the managers continue to charge 2s. 6d. for their two points as they did at the foundation of the Institution. Now the public have a right to complain that they get no advantage from the Government grant. It is, indeed, very scandalous that the managers should pocket the money and make no return. By their acceptance of the grant they become public servants, and we have a right to expect from them some advantage as a requital for the money they receive. This is a subject into which Parliament might most properly inquire.

Whilst the millions of Ireland are perishing of small-pox, this Institution continues with an inhuman avarice to levy a heavy impost upon the means of prevention, of which they are the appointed dispensers to their fellow-countrymen. This tax has, consequently, acted as a baneful restriction upon the dissemination of the lymph. We find that the London National Vaccine Institution has issued in one year 43,993 charges of lymph more than the Dublin Institution since its commencement, fifty-six years ago!

What is the use of the Government professing a desire to promote the practice of vaccination, when it permits such an incubus as this to oppress the exertions of the Irish Practitioners to spread the blessings of vaccination among their countrymen? Let the Government at once withdraw its grant, and institute a new machinery for effecting the object which the Cow-pock Institution has so lamentably failed to accomplish. Dr Long says:

"Not having any vaccine, I wrote to the Institution for it, but did not send any money. I applied the same day by post to the London Establishment, observing to a medical friend that I would not be at all surprised at getting the lymph from London first. It absolutely did turn out so. I got it from London by return of post. How did I fare at the Dublin Institution? I received for answer, that the supply was short, and was requested to send the following Friday (the third day off), before two o'clock. I sent as directed on Friday: my messenger, however, did not arrive until a quarter past two, when he was told that he should come on the following Tuesday. I, of course, did not send again, as I had received twelve points from London, value in the Dublin Cow-pock Institution for 15s. I wonder would I have got two points of lymph if I had sent half-a-crown. I am inclined to think I would: probably if I had sent 5s., I might have received four. I will not stop to discuss the courtesy of the refusal, or the fact of the supply of lymph being so used up in a so-called Public Institution, that it could not afford to give a Medical Practitioner two points. I confess the Institution presents to my mind more the features of a mercantile establishment for the sale of lymph, than that of a philanthropic association."

Enough, then, upon the shortcomings of this Institution. To it we attribute in an important degree the fact that small-pox continues to be the hideous curse of Ireland, and we hope the Government will, on the first opportunity, either revoke the grant, or insist upon a free supply of lymph to every Professional applicant.

THE ANNUAL MEETING OF THE MEDICAL OFFICERS OF ASYLUMS.

The usual Annual Meeting of the Medical Officers of Asylums has recently been held in London, for the purpose of promoting the improvement of the system for the care and cure of the Insane. No more momentous duty can devolve on any class of persons than that discharged by these gentlemen, who are required to bring to its performance the highest science, associated with the utmost tact, gentleness, and insight into the weakness and perversity of our common nature. As Dr Bucknill happily said, "In the world there is nothing greater than man, and mind is the greatest thing in man." How great the responsibility, therefore, of those whose duty it is to deal with that subtle element of humanity in all its capricious wanderings, and unquiet and loosened perturbations!

We observe that a few topics relative to the status and claims of the Medical Officers themselves were touched upon in the course of the meeting. Dr Bucknill especially dwelt upon the necessity and justice of a "Superannuation Fund" in their behalf—a proposal which has our warmest commendation, for, undoubtedly, there are no men whose mental and bodily frames are subjected to a heavier strain by the incessant anxieties incident to their duties. Surely, after a period—say twenty years—of ceaseless vigils,

it is time that the Medical Officer should be able to retire upon the well-earned bounty of the State. Periods of relaxation, too, during the year are equally necessary for the retention of the elasticity and repose of mind so necessary to the satisfactory and efficient discharge of his onerous functions.

For some time past a question has been in dispute, in Ireland more particularly, with respect to the conflicting authority of the Visiting Physicians and the Resident Medical Officers; a question which, though kept in discussion by the admirers of the *status quo*, is nevertheless settled in favour of the latter officers, in the minds of the most experienced and enlightened friends of the Insane. It is obvious to us, that the Resident Medical Officers should be, in a sense, autocratic; that in order that their patients should have the full benefit of their judgment, and special and local knowledge, they should be exempt from the interference of external authority; that, in short, they should be solely responsible for the due administration of their several establishments. To admit a Visiting Physician to the right of influencing or overruling the decisions of the Resident Medical Officer, is to divide responsibility—the most effectual way of insuring misgovernment. Lord Shaftesbury has condemned this practice, and we are glad to observe that Dr Conolly's personal experience is also opposed to its continuance. We commend the observations of that distinguished alienist to the perusal of our readers.

We are pleased to find that the Annual Meeting will be held next year in Dublin, when, no doubt, as Dr Stewart, of the Belfast Asylum, promptly assured the Members, they would meet with a generous reception. The proverbial hospitality of our Irish friends will not lack cordiality on so interesting an occasion, and we may therefore augur with confidence a pleasant and profitable Meeting in the Irish capital.

SUMMARY OF THE WEEK.

DEATH OF DR ADDISON.

Another illustrious name has been added to the roll of those who are registered on the tablets of the memory, and of whom nothing remains to us but the echoes of a useful life. Dr Addison has departed from the scene of his labours, and his place will know him no more. The manner of his death, sad in the extreme, has increased the shock with which we should naturally have regarded the tidings. Within the past year it has been our painful duty to record the decease of three of the most distinguished cultivators of Medical Science—Dr Bright, Dr Todd, and now Dr Addison. The Profession does not contain three other men of equal intellectual endowments, practical sagacity, and fulness of fame. Guy's Hospital may be considered peculiarly unfortunate in losing in the same year its two most eminent Physicians—men singularly alike in scientific character, and perfect examples of the admirable school in which they were trained, and whose reputation they so nobly sustained.

The devotion to pathology which bore such golden fruit in the case of Bright, was scarcely less fertile of good results in the person of Addison; and each has given a name to a new disease—an honour not attained by any other modern Physician. Dr Addison was in the most characteristic sense a *scientific* Physician: he traced all phenomena back to their causes, and endeavoured to explain every symptom by reference to local lesion. The *fact* had the empire of his mind; he bowed down to it as the only sovereign to which his intellect owed allegiance. He pursued it through all its devious paths and disguises, and made it the goal of his researches. Thus it was that his most recent contribution to science—disease of the supra-renal capsules—was discovered. Like all men capable of developing truth, his love of the fact was associated with a speculative turn of thought, and a disposition to evolve general principles. This combination is, indeed, essential to success in scientific exploration. He was the pattern of a philosophical Physician, and it will be long before we shall see his equal.

Dr Addison was a man of retiring manners, naturally shy and self-denying. He was considered by those who judged of character simply by surface signs, to be proud and haughty; a mistake in his case, as in a thousand others of men who are too sensitive for familiarity, and too timid to confront society with the dash which is often the presumptuous man's only passport. He was highly esteemed by his friends and colleagues, who have recently erected a memorial to him in the Hospital. As a Practitioner he did not win great popularity; but it must be added that he never sought it, content rather to possess the good opinion of the experts in science than to take fees by cultivating popular applause. He was a tall, well-proportioned man, with bold, masculine features: but the most powerfully-knit structure bears within it the elements of its own decay, and Dr Addison, not yet old, was a sufferer from a disease of the liver, the indications of which had long been noticed, and which, probably, quickened his observation of the lesions of that and the adjacent organs. This disease unfortunately induced a melancholic state of mind, which disabled him latterly from following his Professional pursuits, and rendered necessary the vigilance and kindness of an attendant. He could not say with the poet—

> "Insanire putas solennia me, neque rides,
> Nec medici credis, nec curatoris egere
> A prætore dati:"

unfortunately, he needed these aids too much but relief was beyond the reach of the art of which he was himself so accomplished a master; his mind grew rapidly more distraught, and in a moment when the eye of his attendant was withdrawn, he threw himself into an area and received injuries that terminated in death. A bright career was thus suddenly precipitated into darkness, and the veil of "mystery" is drawn across the scene.

THE COLLEGE ELECTIONS.

Whether the Fellows of the College of Surgeons, like the Medical Council, were content with the declaration of the College Council that they were sorry for their bad practices, and did not intend to continue them, or whether they felt that there was no time to send in a new list of candidates in accordance with the bye-laws of the College, we cannot say; but it is certain that no attempt was made to substitute new men for the retiring Members of the Council. As a mere matter of routine, however, what a wretched farce is this College Election! Mr Kiernan, Mr Hodgson, and Mr Partridge have been duly elected; whilst outside the College portals remain Messrs Fergusson, Erichsen, Birkett, Adams, Curling, and several more eminent Metropolitan Surgeons. What are the Provincial Surgeons about, moreover, that they are content to allow the Metropolitan men to monopolise the honours of the Council?

AMENDMENT OF THE MEDICAL ACT.

Medical affairs have fallen into such confusion, that we find it difficult to give our readers timely information with relation to contemplated changes. Moreover, it perplexes us to discover where and how the proposed changes originate. Private individuals and corporate bodies propose amendments just as it pleases them; and the Medical Council does nothing, except the passing of virtuous resolutions. In their turn, the Council concoct their amendments; but the Profession obtain very little exact information of these subterranean proceedings. There is a Bill now in Parliament to repeal a clause in the Medical Act, enabling Scotch and Irish Physicians, practising as such, to be admitted into the English College upon the payment of a small fee. Let the Scotch and Irish Physicians look to this. It is the first step backwards to the old class system, if indeed we can be said ever to have advanced a step out of it. Our readers may depend upon it that the Medical Council will make it their duty to serve the interests only of the Corporations they represent. The Licentiates of the Scotch and Irish Colleges have a claim upon those bodies which, vigorously urged, cannot be treated with indifference. There must not be a sinister policy for Corporate aggrandisement to the injury of the Profession at large.

NEW POOR-LAW MEDICAL RELIEF BILL.

By the time that this number of the MEDICAL CIRCULAR reaches the hands of the Profession, it is probable that Mr Pigott will have introduced a second Bill for the amendment of the system of Medical Relief. It is premature at present to detail the clauses of this Bill; but as soon as it is published, an abstract of it shall appear in this Journal.

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, THURSDAY, JUNE 21.

Sir CHARLES HASTINGS took the chair, at three o'clock p.m.

Present—Dr Burrows, Mr Green, Mr Nussey, Dr Acland, Dr Bond, Dr Embleton, Dr Storrar, Dr Alexander Wood, Dr Andrew Wood, Mr Watt, Mr Syme, Dr A. Thomson, Dr A. Smith, Dr Leet, Dr Apjohn, Dr Corrigan, Sir James Clark, Mr Lawrence, Mr Teale, Dr Christison and Dr Stokes.—Dr Francis Hawkins, Registrar.

The Minutes of the last meeting were read and confirmed.

1. There were brought before the Council several Memorials, in regard to recent admissions by the Royal College of Surgeons of England.

Mr Green, the representative of that body, explained that no one had received the diploma of the Royal College of Surgeons of England without having been examined and found qualified in Anatomy, Physiology, and Surgery, and without having been in practice for some years before the passing of the Medical Act, and without having produced certificates of respectable character.

Mr Green having further stated that the practice of examining candidates who had not gone through a full curriculum of study ceased on the 1st of March, and would not be resumed, the Council did not think it necessary to move in the matter.

2. A memorial from some members of the Royal College of Surgeons of England resident in the Isle of Man, relative to the examination of Dentists by that College, having been read,

Dr Apjohn moved, seconded by Dr Storrar—That this Council has no authority to interfere with the privileges, in relation to Dentistry, conferred upon the College of Surgeons of England by charter, in accordance with the 48th Section of the Medical Act.—Agreed to.

3. A memorial having been received from an Association of Foreign Graduates, praying for the Registration of their Foreign Degrees,

Dr Storrar moved, seconded by Dr Alexander Wood—That, by the 11th Section of Schedule (A) of the Medical Act, the Council have authority only to register such foreign qualifications as were possessed by persons practising, by virtue of them, as Physicians in the United Kingdom before the 1st of October, 1858, and who can satisfy the Council that such qualifications have been conferred after regular examination.—Agreed to.

4. A memorial from the Royal College of Surgeons of Edinburgh, relative to Licences in Midwifery, having been read,

Moved by Dr Andrew Wood, seconded by Mr Watt—That as Midwifery forms a branch of the education and examination of every Physician and Surgeon, and is not mentioned in the body of the Medical Act, apart from the qualification of Physician and Surgeon, it is unnecessary and inexpedient that Licences in Midwifery should be specially registered.

Amendment moved by Dr Alexander Wood, seconded by Dr Apjohn—That the memorial of the Royal College of Surgeons of Edinburgh, in regard to Midwifery Licences, be referred to the Committee appointed to consider what amendments are required in the Medical Act.—Amendment carried.

5. Dr Alexander Wood brought up the first Report of the Committee on special claims for Registration :—

FIRST REPORT OF SPECIAL REGISTRATION COMMITTEE.

The Committee have to report that there are five applications from persons having graduated at Homœopathic Colleges in America, viz.—Henry Thomas and Thomas Smith, Homœopathic College of Pennsylvania; Samuel Eadon, James Coombs, and John Marchant Davison, Homœopathic College of Cleveland, Ohio. Of these, Thomas Smith does not profess to have been examined at the College named, and the Committee have no hesitation in recommending that his application be rejected.

In regard to the cases of Henry Thomas, Samuel Eadon, James Coombs, and John Marchant Davison, who have got their degrees after examination at the Colleges named, a considerable difficulty occurs.

It seems that Charters are granted with very great facility by the Legislatures of some of the States of America, and it therefore becomes a very grave question for the Council to decide, how far they are prepared to recognise the bodies so chartered as Foreign Universities or Colleges in the sense intended by the Medical Act.

Samuel Eadon's claim was rejected by a vote of the General Council on the 6th August last, and he has applied for a re-consideration of his case.

Henry Thomas, who claims to be a Graduate of the Homœopathic College of Pennsylvania, has addressed to the Registrar, and to each member of the Branch Council for England, a letter in the following terms :

"SIR,—I hereby give you notice that I am a Doctor of Medicine by diploma, dated the first day of March, one thousand eight hundred and fifty-five, of a foreign College, to wit, the Homœopathic Medical College of Pennsylvania, in the United States of North America;—That I have been practising in the United Kingdom of Great Britain and Ireland, to wit, at Chester, before the first day of October, one thousand eight hundred and fifty-eight; to wit, from the year one thousand eight hundred and fifty-six, hitherto :—That I have produced or forwarded by post to the Registrar of the Branch Council for England my diploma as Doctor of Medicine, and other documents, and evidence of the qualification in respect of which I claim to be registered as hereinafter stated : That I have produced to the Council certificates of my having taken my degree of Doctor of Medicine after regular examination, and have in all respects complied with, and am ready and willing to comply with, the provisions contained in 'The Medical Act,' 21 & 22 Vict., cap. 90 : I now therefore claim to be registered under, and in accordance with, the provisions of the said 'Medical Act;' and I demand that my name be placed upon 'The Medical Register:' And I hereby further give you notice, that if this my demand be not complied with, or a satisfactory reason be not given for the non-compliance therewith within fourteen days, such proceedings will be taken, either by mandamus or otherwise, against you and the Members of the Branch Council of England, either individually or collectively, or both individually and collectively, as I may be advised

(Signed) "HENRY THOMAS.

"Dated this 27th day of January, 1860."

A claim has been presented by Thomas Airey, under Section 11 of Schedule (A).

The Committee are of opinion that Thomas Airey has failed to establish his claim, and ought not to be registered.

ALEXANDER WOOD, Chairman.

Moved by Mr Syme, seconded by Dr Alexander Wood—That the names of Samuel Eadon, James Coombs, John Marchant Davison, and Henry Thomas be registered, in strict compliance with the Medical Act.

Amendment moved by Dr Corrigan, seconded by Dr Apjohn—That the names of Samuel Eadon, James Coombs, John Marchant Davison, and Henry Thomas be not registered.

The following letter was read from the President :

"14 Savile row, W., June 21, 1860.

"MY DEAR SIR,—I will thank you to express to the Medical Council at their meeting this day, that, in pursuance of the notice which I have already given, it is my wish to resign my office as President of the Council before the conclusion of the present session.

"Although circumstances compel me to take this step, I take it with great reluctance, having had so much experience of the kindness and courtesy shown me by every member of the Council since they first did me the honour of electing me to preside over their meetings.

"I am, dear Sir, yours faithfully,

"To Dr Hawkins." "B. C. BRODIE.

Confirmed—B. C. BRODIE.

MINUTES OF MEETING, JUNE 22ND, 1860.

Royal College of Physicians, London.

Dr BURROWS took the chair, at two o'clock p.m.

Present—Mr Green, Mr Nussey, Dr Acland, Dr Bond, Dr Embleton, Dr Storrar, Dr Alexander Wood, Dr Andrew Wood, Mr Watt, Mr Syme, Dr A. Thomson, Dr A. Smith, Dr Leet, Dr Apjohn, Dr Corrigan, Sir James Clark, Sir Charles Hastings, Mr Lawrence, Mr Teale, Dr Christison, and Dr Stokes.—Dr Francis Hawkins, Registrar.

The Minutes of the last meeting were read and confirmed.

1. The adjourned debate on the first Report of the Committee on Special Claims for Registration was resumed.

Mr Syme was permitted by the Council to withdraw his motion—"That the names of Samuel Eadon, Jas. Coombs, John Marchant Davison, and Henry Thomas be registered, in strict compliance with the Medical Act;"—and to substitute for it the following motion, seconded by Dr Storrar :—"That the opinion of the Attorney-General be taken on the claims of Henry Thomas to register his degree obtained from the Homœopathic College of Pennsylvania; and of Samuel Eadon, James Coombs, and John Marchant Davison, to register their degrees obtained from the Homœopathic College of Cleveland, Ohio; and that it be delegated to the Executive Committee, after receiving the opinion of the Attorney-General, to take such steps as may seem to them expedient.

The amendment of Dr Corrigan was put and negatived,—viz., "That the names of Samuel Eadon, James Coombs, John Marchant Davison, and Henry Thomas, be not registered."

The motion substituted by Mr Syme was then put and carried.

2. Moved by Dr Alexander Wood, seconded by Dr Stokes—"That, in accordance with the recommendations of the Report of the Committee on Special Claims for Registration, Thomas Smith and Thomas Airey be not registered."—Agreed to.

Sir Benjamin Brodie, Bart., President, then took the chair.

3. Letters were read from Mr William Gwynn, stating that the University of Dublin had refused to admit him to the Degree of Doctor of Medicine, and to that of Master in Surgery, on the ground that he had adopted a particular theory of Medicine, and requesting "that the Medical Council, in accordance with the Act 21 & 22 Vict., cap. 90, sect: xxiii, will represent the same to Her Majesty's Most Honourable Privy Council."

Moved by Mr Syme, seconded by Dr Andrew Wood—"That the Council resolve that they see no reason for taking any step in relation to the letters of Mr Gwynn."—Agreed to.

4. A Petition was read, which had been transmitted by the Registrar of the Branch Council for Scotland, from Mr J. B. Clarkson, of Melrose, for the reduction of a registration fee.

Moved by Dr Andrew Wood, seconded by Dr Alexander Wood—"That the Council have no power to comply with Mr Clarkson's petition."—Agreed to.

5. A Memorial was read from the Gloucestershire Medical and Surgical Association praying for "better securities for the conviction of illegal Practitioners."

Moved by Dr Alexander Wood, seconded by Sir Charles Hastings—"That the Memorial from the Gloucestershire Medical and Surgical Association be referred to the Committee appointed to consider what amendments are required in the Medical Act."—Agreed to.

6. Information having been laid before the Council, from the Royal College of Physicians of Edinburgh, and also from the Faculty of Physicians and Surgeons of Glasgow, that the name of Mr John Valentine Laverick had been struck off their respective lists of Licentiates;

Moved by Dr Alexander Wood, seconded by Mr Watt—"That in conformity with Clause XXVIII of the Medical Act, the name of John Valentine Laverick be erased from the 'Register,' he having been deprived of the two qualifications in respect of which he has been registered by the Royal College of Physicians of Edinburgh and the Faculty of

Physicians and Surgeons of Glasgow respectively."—Agreed to.

7. Moved by Dr Christison, seconded by Dr Andrew Wood—"That the attention of the Medical Council having been called to Regulations issued under authority of Her Majesty's Privy Council, on December 6, 1859, requiring that all Public Vaccinators shall have undergone in the art of Vaccination, a special education, and a special examination, the particulars of which are minutely laid down in the Memorandum of the Privy Council—the Medical Council resolve that one purpose, and a main one, of the Medical Act, was to ensure that the Members of the Medical Profession shall be duly educated and examined in the various branches of the Profession;—That the Council, with the co-operation of the various Bodies which grant qualifications in Medicine, have assiduously laboured to discharge this function; and do not doubt that, among other results, the important object of the Privy Council will in consequence be fully attained;—That it will be a great discouragement to the Medical Council, and to the Bodies placed by the Medical Act under their superintendence, if other public Bodies issue, for limited branches of professional practice, regulations substantially constituting new and limited branches of the Medical Profession, independent of this Council;—And, therefore, that it be remitted to the Executive Committee to draw up a statement expressing the views of this Council, and to submit the same to the Lords of Her Majesty's Privy Council."—Agreed to.

8. Moved by Dr Christison, seconded by Sir Charles Hastings—"That it be remitted by the Council to the Executive Committee to take such steps as they may consider advisable for promoting the registration of Medical Officers in the Military and Naval Services."—Agreed to.

9. A reference from the Royal College of Physicians of Edinburgh, in regard to the Ordinances of the Universities (Scotland) Commissioners for conferring Degrees in Medicine in the University of Edinburgh, having been read,

Moved by Dr Alexander Wood, seconded by Mr Lawrence—"That the General Council of Medical Education and Registration having taken into consideration the Ordinances of the Scottish University Commissioners for regulating the conferring of Medical Degrees in the University of Edinburgh, dated 6th August, 1859, which were laid before them by Mr Syme, on the 8th of August last, and also the further supplementary Ordinances of the 19th March, 1860, which have been circulated among the Members of the Council, find—

"1st. That having already declared that the higher Degrees in Medicine should be distinguished by corresponding academic rank, obtained by a full, and as nearly as possible equivalent academic education, they are compelled reluctantly to record their opinion that these Ordinances, if carried into effect, will tend to frustrate their efforts in this direction.

"2nd. That having also declared 'That all students should pass an examination in general education before they commence their professional studies,' the Council are of opinion that it is impossible for the generality of students to acquire, before the age of seventeen years (which they must do, if they are to take their Medical Degree at twenty-one years of age), such a general education as shall enable them to prosecute their Medical studies with success, and afterwards to take the position which University Graduates ought to take among the educated classes of the community.

"3rd. That in the opinion of the General Council, the scheme proposed by the Commissioners, by which a Degree in Medicine and a Degree in Surgery are to be given after one Course of Study and one Examination, tends inevitably to establish a fictitious, not a real distinction between a Physician's and a Surgeon's Diploma, and is opposed to the spirit of the Medical Act."

Amendment moved by Mr Syme, seconded by Dr A. Thomson—"That it is inexpedient for this Council to express any opinion at present, with respect to the terms upon which Degrees in Medicine are conferred by the University of Edinburgh."—Amendment negatived.

Dr Alexander Wood required that the names of the majority and minority should be entered on the Minutes.

Majority: Dr Burrows, Mr Green, Dr Acland, Dr Bond, Dr Embleton, Dr Andrew Wood, Dr Alexander Wood, Mr Watt, Dr Smith, Dr Apjohn, Dr Corrigan, and Mr Teale.

Minority: Mr Nussey, Dr Storrar, Mr Syme, Dr A. Thomson, Dr Leet, Sir Charles Hastings, and Dr Christison.

The original motion was then put, and also negatived.

Dr Alexander Wood required that the names of the majority and minority should be entered on the Minutes.

Majority: Dr Burrows, Mr Nussey, Dr Acland, Dr Bond, Dr Storrar, Mr Syme, Dr A. Thomson, Dr Leet, Sir Charles Hastings, and Dr Christison.

Minority: Mr Green, Dr Embleton, Dr Andrew Wood, Dr Alexander Wood, Mr Watt, Dr Smith, Dr Apjohn, Dr Corrigan, and Mr Teale.

Dr Corrigan presented the following Report from the Committee appointed by the resolution of the General Medical Council of June 14, 1860, to consider defects which appear to interfere with the efficient working of the Medical Acts.

REPORT.

"The Committee consider that there will not be sufficient time within the present session to draw up a report that would contain the whole consideration of such an amended Bill as might embrace all the subjects which should be contained in it, and thus obviate the introduction of frequent or partially-amended Bills. The Committee desire in this Report to do no more than draw attention to such points as appear to them, in the limited time they have had for consideration, to require to be amended, feeling assured that, in the interval that will occur between this and the next meeting of the Council, the several Members of the Council will give the subject their attention and deliberate consideration; the Committee also expect that there will be received within the same interval, from the Profession generally, many valuable suggestions. The Committee trust that with these aids, the General Council will be in a position, at no distant time, to prepare such a Medical Bill as may leave little room for alterations for many years to come; and the Committee recommend, with this object in view, that the Council should give the present Act, notwithstanding any acknowledged defects, a full and further trial, in order that they may become thoroughly acquainted with all such defects, and the best means of obviating them.

"The Committee, therefore, in this Report, confine themselves to observations on such Sections as at present appear to them to require removal or amendment.

"Sect. X of the Medical Act of 1858 is the first that appears to require amendment. In this Section, as it nt present stands, the Registrar of the General Council must be also Registrar of the Branch Council of England, and must be paid out of the General Fund such salary as the General Council may direct. The consequence of this arrangement is, that at any time the Branch Council may be left without a Registrar, and it might even be for a long period; for, in the event of a vacancy by death or otherwise, the Branch Council would not have power to appoint a Registrar. And, moreover, the salary of the Registrar of the Branch Council for England, under the present Section, is wholly paid out of the General Fund, to which the Branch Funds contribute; while the salaries of the Registrars of the Branch Councils of Scotland and Ireland are wholly paid out of their respective Branch funds. The Committee, therefore, propose that the Section should stand thus:—'X. The General Council shall appoint a Registrar, who shall act as Secretary of the General Council, and who may also act as Treasurer, unless the Council shall appoint another person or other persons as Treasurer or Treasurers. The General Council shall also appoint so many clerks and servants as shall be necessary for the purposes of this Act; and every person so appointed shall be removable at the pleasure of the Council, and shall be paid such salary as the Council shall think fit.'

"The Section as amended will therefore deal only with the appointments of Registrar and Secretary of the General Council. There is nothing in the Section so amended to prevent the Branch Council from appointing to the office of Registrar of that Council the same person who may be the Registrar of the General Council.

"Sect. XI should necessarily be altered to be in accordance with Sect. X, and would relate to the appointment of Registrar, &c., by all the Branch Councils, and would then run thus:—'XI. The Branch Councils for England, Scotland, and Ireland shall each respectively in like manner appoint a Registrar, and other officers and clerks, who shall be paid such salaries as such Branch Councils respectively shall think fit, subject to the approval of the General Council, and be removable at the pleasure of the Council by which they were appointed; and the person appointed Registrar shall also act as Secretary to the Branch Council, and may also act as Treasurer, unless the Council shall appoint some other person or persons as Treasurer or Treasurers.'

"Sect. XIII. To the alteration proposed in this Section, the Committee request the particular consideration of the Council. As the Section at present stands, all the monies received in fees are payable to the respective Branch Councils; but in the Act there is no provision, and the Committee cannot see how any can be made, to determine to what Branch Councils the several registration fees shall be paid; and the consequence is, that it is possible so large a proportion of the registration fees might be paid into the fund of any one Branch Council as to leave the others without sufficient funds to carry out the purposes of the Act.

"Taking these considerations into account, and further considering that there must be only one 'Register' for the United Kingdom, the Committee are of opinion that all the monies should be paid into a common fund, from which all the expenses of General and Branch Councils should be defrayed, subject, as provided for in Sect. X, to the approval and supervision of the General Council.

"The Section thus amended would be to this effect:—'That all monies payable to the General and Branch Councils shall be payable into one common fund, from which all the expenses of the General and Branch Councils shall be defrayed, subject to the supervision and approval of the General Council.'

"Sect. XIV. The proposed addition to this Section is, 'that if any person registered shall notify to the Registrar that he has ceased to practise, and wishes to withdraw his name from the 'Register,' the Registrar shall have power to erase his name.

"Sect. XXV. It is proposed to erase the words commencing 'in the case of,' and ending with 'Ireland,' in the said Section, to make it accord with Sect. X.

"Sect. XXVII. To make this Section more clear, it is proposed to introduce words to this effect:—'And that he is not possessed of any qualification which would entitle him to be registered in accordance with the provisions of this Act,' to be introduced after the word 'Act,' in the said Section.

"Sect. XXIX. To remove obscurity in this Section, it is proposed to introduce the words 'whether before or after registration,' after the words 'professional respect.'

"Sect. XL. It is proposed to substitute 'or' for 'and,' between the words 'Medicine *and* Surgery,' in two places of the Section where the words 'Medicine *and* Surgery' are used; and to introduce the following words after 'or an Apothecary:' 'or who shall wilfully and falsely take or use the title of Physician, Doctor of Medicine, Bachelor of Medicine, or Licentiate in Medicine or Surgery, Surgeon, General Practitioner, or Apothecary.'

"This alteration is suggested, as it appears to the Committee that if a person registered under this Act, under one title, should assume in addition some title, qualification, or degree to which he is not entitled, the Section would not apply to him, as the penalty, in the present words of the Section, would be only recoverable against him for assuming a title implying that he is registered.

"Sect. XLI. It is proposed that the word 'shall' be substituted for 'may,' before the words 'in Scotland;' and that the words 'or by any other person,' after the word 'county,' be erased, in order to render it compulsory on the Public Prosecutor in Scotland to sue for penalties under the Act.

"Sect. XLII. This Section is proposed to be amended by the addition of the following words to the end of Section: 'who shall be authorised, under direction of the General Council, to hand over to the parties prosecuting the whole or any portion of such penalty towards defraying the

expenses of such prosecution, as may seem fit to the General Council.'

"It would also be necessary to ascertain, by legal advice, whether any Local Acts intervene as to the working of the first part of the said Section, as the Committee are informed that in London the magistrates or law authorities have decided that such penalties are legally payable, under a Police Act, notwithstanding this Section, into the Police Fund of London.

"Sect. XLVII. The portion of this Section commencing with the words 'Provided nevertheless,' &c., to the end of the Section, relates merely to arrangements between the three Colleges of Physicians; and these three Bodies have concurred in the propriety of the repeal of this portion of the Section.

"There remain only some observations to be made with regard to the Licences inserted in the Schedule (A).

"There is in this Schedule provision for inserting the title, 'Fellow, or Member, or Licentiate in Midwifery of the Royal College of Surgeons of England;' and although no similar title is set forth as to the other Bodies, it appears that the Executive Committee felt themselves constrained, under legal advice, to insert in the 'Register,' 'Licentiate in Midwifery of King and Queen's College of Physicians in Ireland,' and 'Licentiate in Midwifery of the Royal College of Surgeons of Ireland.'

"This inequality between the Licensing Bodies appears to require to be removed, either by the omission altogether of the title of Licentiate in Midwifery from the Schedule, or by the insertion of similar privileges in regard to all Universities and Colleges which grant Degrees or Licences in Medicine or Surgery. The latter appears to the Committee the preferable plan; for the omission altogether of Licentiates in Midwifery would lead to the renewed issuing of certificates purporting to be Licences in Midwifery from self-constituted examining authorities, or Medical Officers of Midwifery Hospitals and Dispensaries, over whose proceedings the General Council or the Act could have no control; and, moreover, some of the Public Boards issuing regulations as to qualifications for Public Medical Appointments require special certificates or qualifications in Midwifery.

"D. J. CORRIGAN, Chairman.

"June 22, 1860."

Confirmed—JOSEPH HENRY GREEN.

ANNUAL MEETING

OF THE

ASSOCIATION OF MEDICAL OFFICERS

OF ASYLUMS AND HOSPITALS FOR THE INSANE

IN GREAT BRITAIN AND IRELAND.

The stated Annual Meeting of the above important Association of Pyschological Practitioners was held on the 5th inst., at one o'clock p.m., in the Freemasons' Tavern.

An unprecedentedly large and influential attendance of Members was present on this occasion. Amongst those in attendance were the following, viz.:

Sir Charles Hastings, M.D., the outgoing President; Dr Bucknill, Devon Asylum, the incoming President; Dr Conolly, Hanwell; Dr Kirkman, Suffolk Asylum; Dr Lockhart Robertson, Sussex Asylum, General Secretary; Dr Stewart, Belfast District Asylum, Secretary for Ireland; Dr Manley, Hants Asylum; Mr Ley, Littlemore Asylum, Treasurer; Dr Sherlock, Worcestershire Asylum; Dr Lalor, Richmond District Asylum, Dublin; Dr Campbell, Essex Asylum; Dr Davey, Bristol; Dr William Kirkman, Assistant-Physician, Suffolk Asylum; Dr Harrington Tuke, the Manor House, Chiswick; Dr Paul, Camberwell; Dr Flynn, Clonmel District Asylum, Ireland; Dr Meyer, Surrey Asylum; Dr R. H. Sankey, Assistant Medical Officer, Littlemore Asylum, Oxford; Dr William Wood; Dr Thurnam, Wilts Asylum; Dr Down, Earlswood; Dr Jephson, Hanwell Asylum; Dr Sutherland; Dr Wing, Northampton Asylum; Dr Blount, Bagshot; Dr G. Birkett, Stoke Newington; Dr Hitchman, Derby Asylum; Dr Christie, Pembroke House; Dr Stevens, St Luke's Hospital; Dr. J Miller, Bethnal House; Dr Burnett, Alton; Dr Hood, Bethlem Hospital; Mr Brushfield, Chester Asylum; Dr Jarvis, Massachusetts, U.S.A. (Visitor); Dr Fayrer, Burman House; Dr Blandford, Blackland House; &c. &c.

Sir Charles Hastings having occupied the Chair *pro formâ*, stated that nothing in particular had arisen out of their proceedings to take action upon since the Association assembled in Liverpool last year, and now begged to resign his office as President in favour of Dr Bucknill, which he gladly did to a gentleman of such great and deserved eminence and popularity. (Hear, hear.)

The new President being cordially installed into office, said that the first business of the day would be to read the minutes of their last meeting; which having been done, they were confirmed and signed accordingly.

THE PRESIDENT'S ADDRESS.

The President then proceeded to read his address, which was an exceedingly elaborate and able document, being cheered repeatedly during its delivery, which occupied nearly an hour and a half, but was listened to throughout with the greatest attention and interest. In its wide range of subjects the welfare of the insane was first taken up, which embraced, the speaker said, questions of morality, law, and politics; and in connection with this he referred to the Babylonian monarch, whose insanity was recorded in holy writ, in whose hands and at whose mercy were placed the destinies of a great nation. In the world there was nothing greater than man, and mind was the greatest thing in man—there was nothing equal to it. Mental hygiene, then, was of the utmost importance in every point of view, and could not be too earnestly or ardently studied and cultivated. The influence of religion was a powerful one on the mind of man. Some said that the religion of the Gospel never produced insanity, but how often has the reverse of this been seen! Look, for instance, at the recent great Ulster revival in Ireland—how many were its mental victims! He then alluded to the early history of the Association, which was originally founded by the Medical Superintendents of the Public Asylums. After a few meetings, however, it fell into disuse, and was for many years nearly dead, showing no signs of vitality, until in the year 1853, when it was revivified at a meeting held in Oxford under the able auspices of their excellent Treasurer, Mr Ley—(Hear, hear)—who then and there mooted the question of establishing a Journal in immediate connection with the Association, and which from that time to the present had been in existence, with what effect and success the members themselves could best answer. (Hear, hear.) The Medical Superintendents of Asylums, the speaker in proceeding said, lived in a morbid atmosphere of thought and feeling. No man can properly understand the insane except the man that throws, as it were, his mind into theirs. (Hear, hear.) The number of Mental Physicians who have suffered in the discharge of their office would bear comparison with military officers who had fallen in the field of battle. (Hear.) Their duties and responsibilities were confessedly of the most arduous, anxious, and painfully trying nature. (Hear, hear.) The Medical Superintendent was a species *sui generis;* he was struck out from the world, and secluded with his own most interesting but most responsible charge. (Hear.) It was the Medical Superintendent's solemn duty to leave nothing undone to promote the welfare and well-being in every way possible of a charge so sacred and all-important; he was their captain, their defender from all injustice and mistaken and miserable economy on the part of the sane. (Hear, hear.) Having, then, a charge so onerous, and needing the strongest mind to bear up with its many depressing influences, he (the President) felt himself imperatively called upon before that large and influential meeting of his *confrères* to impress on them the absolute necessity of stated relaxation from their never-ending cares, for otherwise it was impossible for them to discharge their office as Medical Superintendents with due efficiency to their patients, in common justice to themselves and those immediately depending upon them. (Hear, hear.) There should be an entire and a complete change of scene, and, in fact, of country, for the mind even shaken was not so easily restored again to its healthy balance. (Hear, hear.) The Medical Superintendent in his seasons of relaxation should devote himself to some study entirely unconnected with his specialty, and thus strengthen his mind, to enable him to begin his labours afresh; and field sports of all kinds should be had recourse to, for his physical reinvigoration. (Cheers.) Referring to the intended new legislation for Asylums next year, the President said that the Superintendents should, both singly and unitedly, use all and their most untiring energies for the new Bill to contain a statutory provision for defined retiring pensions, as a matter of bounden right, after a certain defined period of service; for, as matters at present stood, they were entirely at the mercy of Visiting Justices and calculating County Sessions, who, so long as the unfortunate Superintendent had any remaining power of work in him, and no matter how long or how conscientiously he had been engaged working in his peculiarly laborious sphere of duty, would throw insuperable difficulties in the way of his enjoying his well-merited reward for years of faithful services. (Loud cheers.) After making some excellent and well-received observations in relation to the Medical proprietors of licensed houses, the necessity of those houses being limited to Medical men, the unjust aspersions cast upon that respectable body by those who ought to have known better, and the very remarkable and all-important fact, that a Select Committee of the House of Commons had now been sitting for three years, and receiving evidence from all sources, friendly and unfriendly, in respect of the management of proprietary houses—that no case had been made out of a sane person having been confined as insane, and this, too, borne out by the evidence of Lord Shaftesbury himself, the Chairman of the Commissioners of Lunacy, the President concluded his eloquently-written address (of which the foregoing is the merest outline, our limits enabling nothing more) with the heartiest plaudits of all present. After a short pause,

Dr Sutherland rose, and in very complimentary terms proposed the marked thanks of the Association to the President, for the valuable and inspiriting address with which he had now favoured them. (Hear, hear.)

Dr Stewart seconded the motion, which, he said, afforded him the greatest pleasure, the whole tone of that address redounding in the highest degree to its author, for its noble spirit of independence and exalted philanthropy. (Cheers.)

The motion was carried with loud applause.

NEXT PLACE OF MEETING.

The next business discussed was the place of meeting in 1861.

Dr Robertson then read a letter he had received from Dr Stewart, their Irish Secretary, in which was given a cordial and earnest invitation, on the part of Dr Lalor of the Richmond Asylum and others, for the Association to hold its next meeting in the Irish metropolis. (Hear, hear.)

Dr Thurnam then moved that the meeting of the Association for 1861 be held in Dublin as he felt that this mark of respect and attention was due to their Irish members, and that for his own part nothing would afford him greater pleasure than to be present on that occasion. (Hear, hear.)

Dr Stewart seconded Dr Thurnam's motion, observing that the Association should bear in mind that the number of members now in Ireland was large and influential; besides, the Association had met in the Scotch metropolis, and if they did not afford the same privilege to Ireland it would be making her a kind of step-child, and cause, he feared, much dissatisfaction. (Hear, hear.)

Mr Ley said that, with every desire to meet the wishes of their Irish friends, it was not convenient to the Association to have provincial meetings continued; but rather that London should be the central point of their operations, and this for various cogent reasons. (Hear.) So much had been done to advance the interests of the Association in Ireland by the continued energy of Dr Stewart, that he (Mr Ley) thought that they would gain nothing more by going there.

Dr Stewart, with great respect, begged to correct the last speaker as to the term provincial being applied to a meeting held in Dublin, which was to all intents and purposes a metropolis as much as either London or Edinburgh—(Hear, hear)—and should not be thus ignored. (Hear.)

Dr Burnett said that he did not feel inclined to attend at any other place but London.

Dr Flynn begged to observe that a meeting held in Dublin would accomplish a large amount of good, and be the means of bringing the Resident

Medical Officers of the Asylums there under the immediate eye of Government, they being essentially Government officials appointed by the Executive, and the Asylums, too, under direct Executive control. He further stated that it was a blot on the Asylums in Ireland, that the Resident Physicians were only so by a supplemental warrant of the Lord Lieutenant, and that, as the law at present stood, there was nothing to prevent persons without the smallest particle of professional knowledge being placed in their charge. (Hear, hear, hear.)

After some further remarks from several Members, the question was ultimately put by the President, for the meeting in 1861 to be held in Dublin, which was carried by a large majority.

APPOINTMENT OF PRESIDENT ELECT.

Dr Lockhart Robertson moved, and Dr Harrington Tuke seconded, that Dr Lalor, the Resident Physician of the Richmond District Asylum at Dublin, be the President for 1861, which was carried by acclamation.

Dr Lalor rose and said, that the great honour now conferred upon him by the Association had taken him quite by surprise, as he felt it was quite unmerited on his part. He could only say further, that he felt deeply grateful for the distinction, and that the Association might depend upon a right hearty welcome to the "Green Isle." (Cheers).

PERIOD OF MEETING IN JULY.

Dr Stewart gave notice of motion, that at their next meeting he would move that a day in the month of July be fixed for the annual meeting taking place—namely, the second Thursday—the existing regulation being uncertain in that respect.

APPOINTMENT OF OFFICERS FOR THE YEAR.

Mr Ley was re-appointed Treasurer, Dr Lockhart General Secretary, and Dr Stewart Secretary for Ireland. Dr Mackintosh, Superintendent Physician of the Glasgow Royal Asylum, was appointed Secretary for Scotland, vice Dr Wingett deceased, and whose removal so prematurely, since the last meeting of the Association, the President referred to very feelingly and with much appropriateness.

Mr Ley, in moving that Dr Bucknill be requested to continue the editorship of the Journal of the Association, said that the utmost economy had always been used by Dr Bucknill, and that he felt the Association should consent to more assistance being given to him than had been the case, the funds in hand enabling this to be done. (Hear, hear.)

Dr Hitchman said the Journal was a most refreshing sight to him each quarter, and cordially seconded the motion, which passed unanimously, on the understanding that for the future the Editor should be at liberty to obtain, and as he had himself suggested, a quarterly digest of foreign Psychological literature and statistics for publication in its pages.

Dr Lalor could not allow that opportunity to pass without stating the deep sense which his Irish brethren, with himself, had of the able manner in which the Journal was conducted by Dr Bucknill, its pages being always replete with invaluable matter; and that the addition proposed would greatly increase its worth, but which of course could not be effected without entailing additional expense. (Hear.)

Dr H. Tuke stated that the sale of the Journal had largely and regularly increased, which showed how highly it was thought of by the Profession generally. (Hear, hear.)

Dr Sherlock and Dr Flynn were appointed Auditors of Accounts.

HONORARY MEMBERS.

Dr Jarvis of Massachusetts, Dr Laycock of Edinburgh, and several other distinguished Psychologists, were now duly elected Honorary Members of the Association, their names having been regularly noticed to the General Secretary and circulated amongst the Members.

Dr Stewart gave notice that at their next meeting he would move that Dr Hatchell, one of the Government Commissioners of Asylums in Ireland, be elected an Honorary Member.

ORDINARY MEMBERS.

Fifteen candidates for Ordinary Membership having been submitted and declared duly qualified, they were elected accordingly; amongst whom were Dr Rorey, Medical Superintendent of the Dundee Asylum, in succession to Dr Wingett deceased; Dr Samuel Hobart, Visiting Surgeon of the Cork District Asylum; Dr Burton, Resident Physician of the Maryborough District Asylum; &c. &c.

STATEMENT OF TREASURER'S ACCOUNTS.

The Treasurer's accounts were now read, having been duly audited, and from which it appeared that the finances of the Association were in a very flourishing condition, a large balance remaining in hands after the payment of all current expenses, and no defaulters in the payment of subscriptions to be reported, and which, it should be remembered, were now due for the current year, being payable in advance, according to one of the standing rules of the Association.

READING OF PAPERS.

Dr Conolly said that his name had appeared on the printed programme for a paper "On the Prospects of Physicians practising in cases of Insanity," which he regretted greatly his inability to read to the meeting then, owing to an attack of face neuralgia; but that this was of the less consequence, owing to the truly admirable address of the President that day, which had anticipated him in some of the principal points he had prepared to bring under the consideration of the Association. He was most anxious that a committee should be appointed to watch every movement now making in respect of new Asylum legislation, and this as well for the purpose of communicating needful knowledge to Members of Parliament as to officials themselves on this most important subject. (Hear, hear.) The proprietors of Asylums, Dr Conolly stated, were placed in great jeopardy, and it had been actually proposed to have Medical detectives placed over them in the persons of provincial Commissioners or Inspectors. (Hear, hear.) After a few further remarks, Dr Conolly concluded by saying that the attention of the Medical Council should be directed to the absolute necessity there existed of steps being taken to make it a *sine quâ non*, for some practical knowledge in the treatment of the insane being required of those seeking to become Medical Practitioners. (Hear, hear.)

Dr Kirkman moved that Dr Conolly be requested to permit his paper to be printed in the next number of their Journal. (Hear.)

Dr Burnett seconded this motion, and stated that it was painful to a degree the invidious remarks to which proprietors of Asylums were exposed on the part of officials. He could not sufficiently strongly express his admiration of the President's address in connection with private Asylums. (Hear, hear.)

The President said he hoped Dr Conolly would yield to the unanimous desire of the meeting by having the paper printed. (Hear.)

Dr Conolly thanked the Association for the expression of their feeling, and promised that he would endeavour to make his communication as complete as possible for publication in the next number of the Journal. (Hear, hear.)

Dr H. Tuke and Dr Lalor moved and seconded that a committee, as suggested by Dr Conolly, be now appointed, and that its members consist of Dr Hood, Dr Sutherland, Dr Campbell, and Dr H. Tuke.—Carried.

Dr Lockhart Robertson now read his paper, as announced, "Suggestions towards a Uniform System of Asylum Statistics," which was well received, and called forth an interesting discussion, which we regret our limits preclude us from giving. The President, Dr Thurnam, Dr Campbell, and Mr Ley, all took leading parts in reference to its contents. A paper by Dr Davey, in regard to Dr Purnell's unfortunate case, was read for him by the Secretary in his absence.

THE RESIDENT AND THE VISITING PHYSICIANS OF THE IRISH DISTRICT ASYLUMS.

Dr Sherlock, Worcester, now rose and said that there was still a very important matter to bring under the special notice of that large and influential meeting of the Association, which had reference to the recently-published pamphlet of their President Elect, Dr Lalor—a paper which reflected the greatest credit upon that gentleman for its ability and spirit. (Hear, hear.) The present issue of their Journal had brought it before their whole body, and the question upon which it bore—namely, the continuance in the Sister Country of officials called "Visiting Physicians"—was one that their Irish brethren had a right to know what the views were of the Association in regard to it. (Hear, hear.)

Mr Ley observed that in England it was only in Lunatic Hospitals supported by charitable contributions that such officers as Visiting Physicians were in existence, and that they served without any salary. (Hear, hear.) Dr Sutherland was not paid at St Luke's Hospital, and the Resident Medical Officer was looked upon in the light of a paid pupil seeking for reputation and ultimately a better position. (Laughter.)

In the public Asylums, however, the patients needed the greatest experience for their care and treatment, and that could be alone afforded by the Medical Superintendent. (Hear, hear.)

Dr Conolly begged to make a few remarks on the very important subject now before the meeting, and in reference to which he held in his hands a resolution to submit to the Association. (Hear, hear.) Without taking too much upon himself, he might be considered to be in a position to speak with some force and authority on the question so properly introduced by Dr Sherlock, he (Dr Conolly) having filled consecutively the offices of Resident Physician, Visiting Physician, and Consulting Physician of the Hanwell Asylum—(Hear, hear)—and the result of his experience was this—that the Resident Physician of an institution for the insane should not be interfered with in the discharge of his important duties by any extern official. (Cheers.) When he became the Visiting Physician of Hanwell, it was owing to a change made by the Visiting Justices, who took up the idea that a military man was the fittest person to be at its head—(Hear, hear)—and accordingly they tried this experiment, but had to abandon it; and whilst he acted as Visiting Physician, he found that the less he interfered with the immediate Medical Officers having the oversight of the male and female departments, the better for the interests of both the inmates and the Institution—(Hear)—and ultimately finding his position as such a very disagreeable one, he voluntarily resigned, though at the time the pecuniary sacrifice he thus made he could not well afford. (Hear, hear.) The Visitors then honoured him with the appointment of Consulting Physician, which he still held; but it was almost needless for him to say that it was an entirely honorary one, and that it was the exception to the rule his ever visiting the Institution in that character. (Hear, hear). His decided opinion, therefore, was an opinion founded upon personal and matured experience, that the Resident Superintendent Physician—the man who lived with his patients, and was alone acquainted and could be alone acquainted with the minute phases of their peculiar malady—should have the entire control—be, in fact, the soul and life of the Institution. (Loud cheers.) Dr Conolly then read his resolution, which was to the effect that in the opinion of the Association the Asylum for the Insane in Ireland should, as in England, have but one responsible Medical Officer, in the person of a Resident Physician, and that if an extra Physician were deemed requisite it should only be for consultation in special cases, at the expressed desire of the Resident Physician. (Hear, hear.)

Dr Campbell had great pleasure in seconding Dr Conolly's well-framed and well-timed resolution. (Hear.) He did not wish to occupy the valuable time of the Association, but he must relate what occurred to himself some time since, when in Dublin, and paying a visit to the Richmond Asylum in that metropolis, but before Dr Lalor's appointment. He, after going through some of its wards, did not think much of the general aspect of the place or of its management, and on asking the official who went round with him some questions in relation to its internal conduct, he (Dr Campbell) at once got the clue of this unsatisfactory state of things, for, to his amazement, he was told that the Asylum was favoured with the presence of three visiting Medical Officers daily, and that each gave contrary orders and different medicines to the other. (Great laughter.) This was his personal acquaintance with the Metropolitan Lunatic Asylum of Ireland. (Hear, hear.)

Dr Thurnam and others having spoken in support of the resolution of Dr Conolly, the President put it from the chair, and it was carried unanimously.

After some further business, the proceedings of this interesting and important Association were concluded with a warm vote of thanks to the President for his very able and dignified conduct in the chair during his arduous day's duties.

DINNER IN THE FREEMASONS' TAVERN.

In the evening the Association dined together in the above place, between thirty and forty being present on occasion of this happy reunion, Dr Bucknill presiding, and on whose right and left, respectively, were seated Dr Mayo (President of the College of Physicians), Dr C. J. B. Williams, and Dr Jarvis, who had been invited as guests. The dinner was a most sumptuous one, and the dessert and wines unequalled for excellence and variety. Altogether this social *finale* of the Association's meeting this year was of the happiest and most pleasing kind, and calculated to unite the members of a specialty of such importance in the choicest bonds of friendship and good-will.

MORTALITY OF CHILDREN IN MINES. — It appears from recent reports that the mortality in the mines, of children between the ages of ten and fifteen, is very great. The whole mortality is 11½ per cent.; but that amongst children of the ages above mentioned is 22 per cent.

DR ADDISON.

It is our painful duty to announce the death of Dr Addison, the late distinguished Physician of Guy's Hospital. The melancholy event took place at Brighton, on Friday, June 29th. Within a few months we have had to record the decease of two of our greatest Physicians, Bright and Todd, and now we have to add to them the name of Addison, whose health began to fail soon after Christmas. He used to say about that time that he missed his usual holiday; and soon finding that he was unequal to the discharge of his Hospital duties, he resigned his public appointment, and soon afterwards relinquished altogether his practice.

Addison was born near Newcastle; but in what year we are at present unable to say, though we think his age at death was about sixty-seven. He was sent to Edinburgh to pursue his professional studies, and took his degree in the year 1815. He subsequently came to London, and was appointed House-Surgeon to the Lock Hospital, where he acquired so great an interest in the subject of syphilis that, although scarcely appertaining to his branch of the Profession, he always considered himself an authority on the subject. He afterwards took a house in Hatton-garden, and attached himself to the Public Dispensary, at the same time becoming a pupil of the celebrated Bateman. He by this means became so great a proficient in the knowledge of Skin Diseases, that it was allowed by all his friends that upon Addison had fallen the mantle of the great dermatologist. This, however, was not generally known, as he did not wish to pursue the subject as a speciality; but it is certain that, until within the last few years, Addison had scarcely an equal in the power of discriminating cutaneous eruptions—a statement which scarcely needs corroboration by pointing to the unrivalled collection of wax models of skin diseases in the Museum of Guy's Hospital, and which for so many years were made under his entire superintendence. His great practical knowledge procured him the appointment of Assistant-Physician to the Hospital in 1824, when his fame rapidly spread among the pupils, and he became a brilliant acquisition to the new School. He was among the first to appreciate the great discoveries of Laennec; and while some of his seniors were sneering, he boldly put in practice all the principles of the celebrated Frenchman. Addison thus soon became proficient with his stethoscope, and was distinguished for his splendid diagnosis of chest affections. Here, again, had he made these the subject of a speciality, he might have rapidly risen into public fame; by his not doing so, he has constantly been heard to say, that, as regards worldly prudence, he was very unwise. His clear perception of disease was not all: he was equally ready in imparting his knowledge to others, and his fluency in debate at the Physical Society had not passed unnoticed. He was consequently appointed Lecturer on Materia Medica in the room of Drs Cholmeley and Back in the year 1827, and soon obtained the best class in London. At that time, when Medical Students paid fees for separate courses, they sought throughout the metropolis for the most attractive lecturer; Armstrong was drawing a large class for the Practice of Medicine at the Webb-street School, and most of his pupils remained to hear Dr Addison. His fees for the course could not have been much less than 700*l.* or 800*l.* In the year 1837 he was appointed Physician to the Hospital, and at the same time joined Dr Bright in the Chair of Medicine. At this period he commenced to publish, conjointly with the above-named Physician, a work on "Medicine." One volume only appeared, which was very highly estimated; and now that both authors have departed from their labours, there can be no harm in the statement that the greater portion of the work was from the pen of Dr Addison. On Bright's retirement from the Chair of Physic in 1840, Dr Addison took it wholly, while Dr Golding Bird succeeded to Materia Medica. Addison's other contributions to Medical literature can scarcely be called numerous, considering the vast amount of knowledge which he was capable of imparting to the Profession; these, though few, are mostly to be found in the well-known "Reports" of the Hospital. The most important, no doubt, are those pertaining to the subjects of pneumonia and phthisis; we believe he was the first to announce the doctrine now generally admitted, that the inflammatory exudation in pneumonia took place into the air-cells of the lungs, and not into any supposed parenchyma of the organ; and as regards phthisis he was a powerful advocate for the doctrine that the most important morbid processes in this disease were due to inflammation. He asserted this with the utmost determination, and principally with the view of opposing the prevailing opinion that the whole disorganising process in phthisis is due to tubercle. He maintained that tubercle was very frequently not present; and he was never tired of relating how in some most advanced cases of the disease he had been asked by Practitioners whether he believed tubercle had yet formed or not. Addison also published, in the same work, some eminently practical papers on the cerebral affections of Bright's disease, on fatty liver, &c. There was not, however, one subject relating to his Profession in which he was not deeply interested. His whole thoughts were concentrated on his business; and being a man of wonderful shrewdness and acumen, he was eminently the practical Physician. This is the term by which, above all others, he would no doubt have preferred to be distinguished. All who knew him must remember how strongly his word *practical* was insisted on by him in the study of disease; it is, indeed, the word which constitutes the key to Addison's whole character and Professional career. He was not adverse to novel theories, and was always ready to discuss them; but he never for a moment allowed them to stand in the way of his more matured experience. Having immense perceptive powers—being shrewd and sagacious above the average of men—when he had his patient before him he looked him through and through, so that few diseases could escape his penetrating glance. He never reasoned upon a half-discovered fact, but would remain at the bedside for a period which would often weary his class, determined to search out the malady to its very bottom. If he could then lay his finger on the seat of disease, his victory was complete. Diagnosis was his forte; and those who knew him best are aware that he stood unrivalled in his power of searching into the complex framework of the body, and dragging the hidden malady to light. When this was done, we fear that nearly all was accomplished; for his very meagre and simple prescriptions (if he remembered to prescribe at all) showed that he made no study of therapeutics. It may be clearly discerned from this what the character of his private practice at Spring gardens must have been; why he never obtained public celebrity, and never could have become the fashionable Physician. Instead of having his house full every morning, he was comparatively unknown to the public, who can scarcely do more than appreciate the superficial qualities of the man; but his profound knowledge of disease could not be unknown to the Profession, and thus he acquired the higher honour (though the less remunerative one) of being consulted by his Medical brethren in their most difficult cases, and his decision when pronounced was deemed somewhat oracular. This peculiarity of his practice will explain, in some measure, the charges made against Addison, that he was too apt to regard all maladies as of a too serious kind, and that he was seldom content until he could fix the symptoms upon some local organic disease. His constant work at the Hospital, where few but serious cases are admitted, and the peculiarity of his practice just named, no doubt, produced such a tendency of thought. This was also increased by his daily attendance in the post-mortem room, from which he was rarely absent until the last two years of his life. He was thoroughly conversant with morbid appearances, and, indeed, it may be safely said that few Physicians are ever so good pathologists as Addison was. It might thus be certain that if he had a serious case before him, and failing to find any local organic disease, was forced to use such an expression as anæmia, that it implied something serious; and many a Practitioner could tell of his consternation when Addison pronounced the name "idiopathic anæmia." And this reminds us of his late great discovery, which, although of very little practical importance in connection with Addison's career as a teacher, will do more than any other circumstance to perpetuate his name; and in this again we perceive his wonderful acumen. By power of observation and clear perception, he alighted upon a fact connected with the supra-renal capsules of far more importance than all which the experiments and researches of learned Germans had previously gained by years of labour; one cannot but remark an exemplification of English character in this respect. It were scarcely necessary to state to scientific readers how fallacious is a very popular opinion that discoveries come by chance, but that they are the fruits only of long investigation. In this very matter, no Physician, but one well acquainted with all the ordinarily well-known morbid processes in the body, and at the same time "well up" in cutaneous affections, could have alighted on the discovery, and therefore, although we consider that every novel doctrine should be well exposed to thorough investigation, none but those entirely ignorant of Addison's character could suppose that, after half a century's experience, he would hazard any statements that were not worth profound consideration, or that could at once upset by the most superficial observations. The very last case of the disease which came before Addison in hospital practice, he asserted to be the most perfect which he had ever witnessed, and directed that models should be taken of the dark-coloured skin: the lad soon after died, verifying his positive diagnosis. This was the example related to the Medical and Chirurgical Society at their very last meeting, it being Addison's wish that Dr Aldis should exhibit the models at a Society of which he had once been President. It may be remarked that neither Addison nor his friends ever suggested that his name should accompany this most remarkable affection, it being styled simply *melasma supra-renale*, but being at once recognised in France, the term Morbus Addisonii was applied, we think, by Trousseau. Thus, by a curious coincidence, on adjoining compartments of the Museum at Guy's Hospital may be seen specimens of Morbus Brightii and Morbus Addisonii, perpetuating the names of those who were intimately allied during life.

We must, in conclusion, say a word in respect to Addison's character. Looking upon it professionally, none ever stood higher; we have never heard of a single instance where a word of disparagement passed his mouth against a Professional brother. His whole bearing was honourable in the extreme, and anything like jealousy or ill-will against another man never entered his thoughts. The estimation in which he was held by his colleagues is signified by the fact of their subscribing together to present the Hospital with his marble bust. This, an admirable likeness by Towne, now adorns the Museum. He was for many years recognised as the spirit which influenced all the Medical doings at Guy's Hospital, and to Addison is due in great measure the high character which the Medical department of the Institution has for a long time evinced. It would be unfair to our readers to overlook in Addison a peculiarity in his manner which no doubt militated against his ever attaining an extensive practice, and which was displeasing to many Professional brethren: we allude to a certain bluntness or rudeness, as it was sometimes called, in his expression towards them, or an *hauteur*, as others would designate it. Those who complained were impressed at the same time with his dignity of bearing, and assumed for him a very great physical and moral energy; they regarded his somewhat unapproachable manner as a haughtiness and an assumption of a superior position. Having known Dr Addison for several years, we are convinced that such an estimation of his character was wrong, and we need, indeed, scarcely point to human nature generally to remark that a quick or hasty manner often covers a mind which has not in itself the greatest controlling power. The latter is to be found rather in the placid and even-tempered man. So with Addison—we believe his apparent resolute and energetic manner rather betrayed a weakness, and from conversation with him, we have his word that this was the case. We know that no brain could be more susceptible than his, and that, although wearing the outward garb of resolution, he was, above all others, liable to sink under trial. He used to tell his class how, when a young man and anxious about his future career, a friend touching him on the shoulder in the street would send a thrill of horror through him. During the last two years trivial matters connected with his retirement from the Hospital were a perpetual worry to him, and other matters affected his susceptible

mind. We use the term advisedly and purposely to vindicate Addison's character from the unamiable spirit which we have heard charged against him. A trial in which he was engaged harassed him, and soon afterwards the death of his friend Dr Todd seemed entirely to upset him. He had only lately had an attack of gall-stones, having previously suffered from this distressing complaint, accompanied by jaundice. He became despondent about his health, resigned his office at the Hospital, and soon after retired from his new house in Berkeley square. Probably nothing could have been worse for his health, for being out of harness, he settled down into a state of melancholy from which nothing could arouse him, and closed his career last Friday week. His last communication was a letter which he sent to the pupils of the Hospital, who had written a letter of condolence on his retirement. We have been favoured with this note, and will give it below, as it affords some characteristics of the man. We would say, in conclusion, that in hurriedly writing these few remarks, we have not sat down to pen an eulogy on Addison, but we would say to those who may at any time have been ever vexed with his uncourteous manner, to take the explanation we have offered, and give thanks to God that thay have been blessed with a calmer and less perturbable spirit.

The following is Dr Addison's last letter :—

"March 17, 1860.

"My Dear Sir,—A considerable break-down in my health has scared me from the anxieties, responsibilities, and excitement of the Profession, whether temporarily or permanently cannot yet be determined; but, whatever may be the issue, be assured that nothing was better calculated to soothe me than the kind interest manifested by the pupils of Gny's Hospital during the many trying years devoted to that Institution.

"I can truly affirm that I ever found my best support and encouragement in the generous gratitude and affectionate attachment, as well as my proudest reflections in the honourable and most exemplary conduct, of its pupils. Present my sincere regards and best wishes to every one of them, and believe me, "Yours truly and affectionately,

"E. Galton, Esq." "Thomas Addison."

—*From the* 'Medical Times and Gazette.'

Births, Marriages, and Deaths.

BIRTHS.

Burns.—June 26, at Brompton, near Chatham, the wife of Dr Burns, Surgeon R.N., of a son.

Douglas.—June 20, at Workington, the wife of T. S. Douglas, Esq., M.R.C.S., of a daughter.

Fletcher.—July 3, at Lever street, Manchester, the wife of James Ogden Fletcher, M.D., of a son.

Glissan.—At Leonard square, Finsbury, the wife of J. Glissan, Esq., M.R.C.S., of a son.

Latham.—June 28, at Greenford, Middlesex, the wife of R. G. Latham, M.D., of a daughter.

Sutro.—July 1, at Finsbury square, the wife of S. Sutro, M.D., of a daughter.

MARRIAGES.

Cuddon—Leake. — June 27, at St George's Cathedral, Southwark, Edward, third son of the late James Cuddon, Esq., of Norwich, to Annette Catherine, eldest daughter J. Leake, M.D., of the Old Kent road.

Hulke—Backhouse.—June 28, at St George's, Bloomsbury, Frederick Thomas, fourth son of William Hulke, Esq., M.R.C.S., of Deal, to Charlotte, only daughter of the late Thomas Cuthbert Backhouse, Esq., and granddaughter of the late John Iggalden, Esq., of Russell square.

Nason—Biddle.—June 28, at All Saints, Edmonton, John James Nason, M.B., of Stratford-upon-Avon, to Mary W. Biddle, second daughter of H. Biddle, Esq., M.R.C.S., of Edmonton.

Smith—Campbell.—June 26, at King's College, Aberdeen, Robert Smith, M.D., of Sedgefield, Durham, son of the Rev. Robert Smith, D.D., Senior Minister of Old Machar, to Jane Macdiarmid, eldest daughter of the Very Rev. P. C. Campbell, D.D., Principal of the University and King's College, Aberdeen.

DEATHS.

Dewar.—Recently, Alexander Dewar, Surgeon R.N.

Donnelly.—Felix A. Donnelly, Surgeon R.N.

Eccles.—June 27, at St Thomas's street, Southwark, William Charles Eccles, Medical Student of Guy's Hospital, aged 30.

Francis.—June 28, at St Mary Elms, Ipswich, James Ougham Francis, M.R.C.S, Eng., L.S.A. Lond., aged 63.

Hughes.—Joseph H. Hughes, Surgeon R.N.

Isaacs.—June 16, at Brooklyn, New York, Charles E. Isaacs, M.D.

Macintosh.—July 2, at 6 Bury street, St James's, Andrew Macintosh, M.D., late of H.M.'s Madras Medical Service.

Nicholson.—July 1, at Phœnix street, Somers Town, aged 7 months, Sarah Elizabath, daughter of W. H. Nicholson, Esq., M.R.C.S., late of Old street, St Luke's.

Reeve.—July 3, at his residence, Moreton terrace, Kentish Town, Henry Reeve.

Roberts.—William O. Roberts, Assist.-Surg. R.N.

Somerville. — June 25, at Florence, William Somerville, M.D., formerly one of the Principal Inspectors of the Army Medical Board, and Physician to the Royal Hospital at Chelsea, aged 91.

Strother.—June 27, at Darlington, Durham, Arthur Strother, F.R.C.S. Eng. 1856, M.R.C.S. 1827, L.S.A. Lond., aged 57.

Tanner. — June 27, John Marshall Comins Tanner, of Torquay, Devon, M.R.C.S. Eng., L.S.A. Lond.

Whitmarsh.—John Whitmarsh, Assist.-Surg. R.N.

Young.—June 30, James Forbes Young, of Upper Kennington lane, M.D. Edin., L.S.A. Lond., a Magistrate and Deputy-Lieutenant of the County of Surrey, aged 64.

MEDICAL NEWS.

Royal College of Surgeons.—The following Members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on the 4th inst. :—Thomas Bancks, Stourbridge, Worcestershire—diploma of membership dated April 29, 1834; Charles Percy Croft, Woburn square—Dec 13, 1839; Thomas Sunderland Harrison, Frome, Somerset—Dec. 7, 1821.—The following gentlemen were admitted Members on the 22nd ult. :—William Henry Brecknell, Gateshead; Henry Croucher, Bexley; Augustus Frederick Elliott, Exeter; George Harrison, Grosvenor street, Grosvenor square; John M'Donnell, Stoke Newington; James Mark Morris, West Bromwich; Christopher Williams, Williton.

Apothecaries' Hall.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, June 28th, 1860 :—George Henry Case, Fareham, Hants; William Hicks Farrington, Ottery St Mary, Devon; Frederick Griffiths, Huntingdonshire; William Seton Johnson, Maidstone, Kent; Robert Charnley Smith, Great Ancoats street, Manchester. The following gentlemen also on the same day passed their first examination : — William Batho, King's College; George Sealy, King's College.

King and Queen's College of Physicians in Ireland.—Mr John Richards, Bangor, North Wales, was admitted a Licentiate of this College on the 18th ult., having previously undergone the required examination.

Collegiate Election.—The annual election of Fellows of the Royal College of Surgeons into the Council took place on Thursday last, when the retiring members, Messrs Hodgson, Kiernan, and Partridge, were unanimously re-elected.

Appointment.—Dr Christopher Dresser has been appointed Professor of Botany at the London Hospital Medical College.

The Medical Council of Education and Registration.—At a meeting of the Council of the Royal College of Surgeons of England on the 4th inst., Mr James Moncrieff Arnott, F.R.S., President of the College, was elected as the representative of that institution in the Medical Council of Education and Registration, in the vacancy occasioned by the promotion of Mr Green to the President's chair, *vice* Sir Benjamin Brodie, Bart., resigned.

The Rank of Military Medical Officers in the French Army.—An Imperial decree, dated June 18th, fixes as follows the rank of military medical officers in the French army :—Inspectors of Hospitals, as Major-General. Principal Surgeon of 1st class, as Colonel; ditto, 2nd class, as Lieutenant-Colonel. Surgeon-Major of 1st class, as Major; ditto, 2nd class, as Captain. Assistant-Surgeon of 1st class, as Lieutenant; ditto, 2nd class, as Ensign.

Magnesium a Source of Light. — This rare metal inflames at the temperature at which bottle-glass softens. According to M. Bunsen, the light of the solar disc exceeds that of inflamed magnesium only by 524·7. M. Schmitt therefore recommends the use of the flame as a source of light at night for photographers, especially as the photo-chemical power of the sun only exceeds by 36·6 that of the flame of magnesium. M. Nickles (in the 'Journal de Pharmacie) says that M. Schmitt seems not to have considered the volatility of the metal, which, according to Daville and De Bray, has its points of ebullition nearly the same as zinc.

A Ball in the Chest.—The post-mortem examination of the body of Prince Jerome led to the discovery of a ball which had remained in his chest after a duel which he fought in his youth with a brother of Marshal Davoust.

The trustees of Owen's College, Manchester, in connection with the University of London, have resolved to found a chair of Natural Philosophy, in which science is to be taught mathematically and experimentally. The salary is 200*l.* per annum, with a proportion of the fees. Candidates must apply to the trustees, not to any individual trustee.

Ozone.—M. Schrotter (Secretary of the Academy of Sciences at Vienna) has discovered ozone in the mineral kingdom. A violet-coloured variety of fluorate of lime, from the stratified granite of Welsendorf, in the Upper Palatinate, on rubbing, gives out an odour resembling hydrochloric acid, and on examination by M. Schrotter has been found to manifest energetically all the reactions proper to ozone. Future researches will be laid before the Academy, in whose reports they will be published.

Supposed Discovery of the Origin of the Vaccine Matter.—The French Medical papers have, for the last few days, been repeating that M. Lafosse, Professor at the Veterinary School of Toulouse, has *discovered* the origin of the vaccine matter. The sober truth is, that M. Lafosse has inoculated the pus taken from the sores of horses suffering from grease, upon a cow two years old, and obtained fine vaccine vesicles, three children being subsequently vaccinated successfully with the lymph contained in the latter. Now, every one knows that Jenner considered the cow-pox as originating from the grease. He had inoculated the pus of old greasy ulcers, and not the lymph contained in the vesicles which appear at the outset of the disease, and failed. The lymph has now been tried by M. Lafosse, with the results stated above; but it should be recollected that others have failed in the same experiment. It is extremely probable, as very justly observed by the Editor of 'La France Médicale,' that the success and the failures depend on certain peculiarities which have not as yet been ascertained.

Buffon before the Academy of Sciences of Paris.—On the 18th ult., great sensation was excited at the Academy of Sciences of Paris by the following statement of M. Flourens :—In the archives of the Academy a sealed envelope had been discovered, entrusted to the secretary, by Buffon, in 1748; and as more than a century had elapsed since the deposit of the paper had been made, the Academy was entitled to break the seal. The envelope contained a paper relative to the history of generation, being the analysis of the chapters forming the 'Treatise on Generation,' which forms a part of Buffon's great work, 'The Natural History of Animals.' It would appear that the great naturalist had been assisted in his labours by persons who thought proper to take advantage of his original views without acknowledgment; and Buffon therefore states, in the paper lately unsealed, that he entrusts it to the Secretary of the Academy, in order to established his priority.

Defiling Drinking-Fountains. — A case brought before Mr Burcham, at the Southwark Police-court, indicates the necessity for affording legal protection to the public from offence or injury through defilement of the public drinking-fountains. A young costermonger was brought up charged with washing filthy fish in the drinking fountain attached to the church wall in High street. Obviously, if the fountains be not kept clean and wholesome, they will neither attract nor serve the public. Probably, legislation will now take place on the subject, attention having been thus directed to it.

Natural History of Stone in the Bladder. —A fisherman, presented, says M. Zennaro, of Chioggia, ('Gaz. Med. Ital.,' 1859,) symptoms of

stone in the bladder at the age of fifty-four, and refused all surgical interference. Seven years afterwards, a fistulous aperture showed itself in the scrotum, and the man was obliged to keep his bed. During the following fourteen years, five more apertures formed between the scrotum and penis, the patient suffering, in the meanwhile, great torture. When seventy-five years old, he had suddenly a sharp attack of pain, and, during the piercing cries he uttered, a calculus weighing eight ounces escaped from one of the perineal openings. The urine then freely escaped by this aperture; but the man still refused all interference, and put up with this inconvenient mode of micturition.

REVIVALS AND INSANITY.—Dr Howden, in an able Report of the Montrose Lunatic Asylum, says with regard to some cases in which insanity was stated to have originated in religious excitement: "The number of instances in which insanity is said to have originated in religious excitement has been very considerable; but in seven only could I satisfy myself, after the most careful and candid investigation, that such was really the case. In these the patients' relatives had no doubt whatever as to the origin of their attack; and each of them after recovery—for they all recovered—most unhesitatingly corroborated the opinion of others. Four of them were persons of strong religious convictions before the commencement of the revival movement, and I ascertained that the others had led regular and exemplary lives for some years previous to their illness. It is a common impression, and, as far as my limited experience goes, an erroneous one, that in such cases the terrors of hell and of a future judgment, held up to the excited imagination, act immediately in disturbing the mental equilibrium. The individuals alluded to above, on the contrary, either had, or believed they had, 'found peace;' and it was the overwhelming excitement and joy attendant on this belief that produced insanity. The mind constantly occupied with one subject, neglect of regular hours, want of sleep, late and early attendance on prayer-meetings, foolish attempts to teach others—a vocation for which they were ill adapted—in fact, a direct contravention of the laws of mental and physical health, combined to produce their natural result—mental disease. One gentleman succumbed to the anxiety and distress of mind occasioned by unsuccessful attempts to address an audience. Another was so overjoyed by his conversion that he scarcely eat or slept for a week, and his joy culminated in an attack of most violent mania. A man who became affected by powerful emotional disturbance, was considered by those who had seen such cases in Ireland to be a genuine example of 'striking down,' and he was treated accordingly, until his 'physical manifestations' became of too turbulent a character to be controlled out of an asylum. In some instances the insanity assumed the type of violent mania—one of them perhaps the most extravagant case I have ever witnessed during the brief paroxysms of excitement; and it is somewhat remarkable that in one individual only were delusions of a religious cast present accompanying a deep melancholia. As I formerly mentioned, all of these persons recovered; all of them were convinced in their own minds of the cause of their illness, leaving the Asylum with a firm determination to avoid for the future an excitement which had proved so perilous to them."

APPOINTMENTS FOR THE WEEK.

Wednesday, July 11.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, July 12.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2½ p.m.

LONDON HOME.—2 p.m.

Friday, July 13.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, July 14.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, July 16.

Operations at the Royal Free Hospital, 2 p.m.; Metropolitan Free Hospital, 2 p.m.

Tuesday, July 17.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

Middle-Class and Non-Gremial Examinations: *Cui Bono?* By A. H. Wratislaw, M.A. Macmillan and Co.

Spinal Curvatures and Deformities of the Chest and Limbs. By Mrs Godfrey. Third Edition. London: John Churchill.

The Wife's Domain. By Philothalos. London: John Churchill.

Diseases of the Heart. By W. O. Markham, M.D. London: John Churchill.

The Causes of Death of many of the Animals at the Zoological Gardens, Regent's Park. By Edwards Crisp, M.D. London: Taylor and Francis.

Benefits of the Agricultural Museum. By Edwards Crisp, M.D.

Thirtieth Annual Report of the Belfast District Hospital for the Insane Poor. 1860.

Rational Medicine, its Position and Prospects. By Stephen H. Ward, M.D. London: John Churchill.

Additional Notes on the State of the Medical Profession. By Edwin Lee, M.C.D., &c. London: John Churchill.

Statistics of Midwifery. By Robert Dunn, F.R.C.S.

The Tegumentary Differences of Man. By Robert Dunn, F.R.C.S.

NOTICES TO CORRESPONDENTS.

A REFORMER, who qualifies his signature by adding "when reform was a reality," has written us a letter "*de omnibus rebus.*" He wishes to know, among other things, "What Sir Charles Locock has done to qualify him to represent the University of London in Parliament?"—a very perplexing question truly. He has gained a large practice, and, perhaps, much money; but we are not aware that he is well acquainted with medical affairs, or that he has added any new fact or principle to science. Again,—"Is Mr Green a reformer or an oligarchist?" Perhaps he will kindly propound his question to Mr Green, for we are unable to answer it. Further, "What is the MEDICAL CIRCULAR about to allow the humbug of a Medical Council to go on extracting money for no useful earthly purpose?" The CIRCULAR is doing its duty: this we can say without fear of a contradiction.

OMEGA.—You are right in your opinion.

Dr J. H.—Either gentleman may be relied on.

Mr WELCH.—Yes.

PHILO-CIRCULAR is thanked for his communication.

X. Y. Z.—The law of the case is not yet determined, but we have no doubt that the judgment will be in favour of a liberal construction. We have nothing to add or amend in the commentary on the Act published in this journal when the Act was first passed.

Dr MCGREGOR.—1st. Yes.—2nd. Yes.

A SUBSCRIBER should write to the War-office for information.

Mr J. H. R.—1st. Not without examination.—2nd. It could not be registered.

A SUBSCRIBER (Lynn).—Certainly.

CHIRURGUS cannot do better than read carefully the numerous papers on the operation in the MEDICAL CIRCULAR. Mr Baker Brown has written a book on the subject, which Chirurgus can obtain.

M.R.C.S. ENG.—You are eligible.

A POOR-LAW SURGEON.—The Guardians may grant the fee; but it is not compulsory on them to do so.

H. H.—The Lectures (so called) were never delivered.

THE MEDICAL COUNCIL.—FOREIGN M.D.s.

To the Editor of the Medical Circular.

SIR,—I took the trouble of wading through the 'London and Provincial Directory' to ascertain how many practitioners had taken the M.D. diploma abroad. I find 196 gentlemen had done so. I then took the 'Medical Register' to see how many of these diplomas the Medical Council would recognise: the result—sixty-four only are on that 'Register'—as follows:

Diplomas obtained.—Erlangen, 71; Giessen, 32; Jena, 14; Heidelberg, 22; Bavaria, 1; United States, 11; Tubingen, 2; Havanna, 1; Bologna, 1; Padua, 1; Placentia, 1; Berlin, 11; Brussels, 1; Paris, 1; Wurzburg, 3; Leipsic, 3; Gottingen, 1; Pavia, 3; Leyden, 6; Pisa, 8; Munich, 3: total, 196.

Diplomas recognised by Council.—Erlangen, 3; Giessen, 13; Jena, 1; Heidelberg, 12; Bavaria, 0; United States, 2; Tubingen, 0; Havanna, 0; Bologna, 0; Padua, 0; Placentia, 0; Berlin, 9; Brussels, 1; Paris, 1; Wurzburg, 3; Leipsic, 2; Gottingen, 1; Pavia, 2; Leyden, 6; Pisa, 5; Munich, 3: total, 64.

From the above statement it will be seen that out of 196 diplomas obtained at foreign universities, only 64 were recognised by the Medical Council. This is weeding with a vengeance. What does it all mean? Yours, &c., PAUL PRY.

LETTERS received from H. S. Leverton, R. Griffin, A. M. Jones, &c. &c.

A Lady wishes to meet with a Re-engagement to take charge of an Invalid or Insane Patient. She can offer undeniable references and testimonials of ability and experience.—Apply, by letter, to "H. P.," Post-office, High street, St John's wood, London.

To Surgeons and Chemists.—To be disposed of, a good Ready-money Retail Business and Practice at the West End, established 20 years. Immediate possession may be had. Terms, under 100 guineas.—Apply to "C. F.," Alpha road, Regent's park, N.W.

The London Home for SURGICAL DISEASES OF WOMEN, 16 Stanley Terrace, Notting Hill.—This Hospital is established for the treatment of surgical diseases peculiar to women, and combines the organisation of a hospital with the comforts of a home.

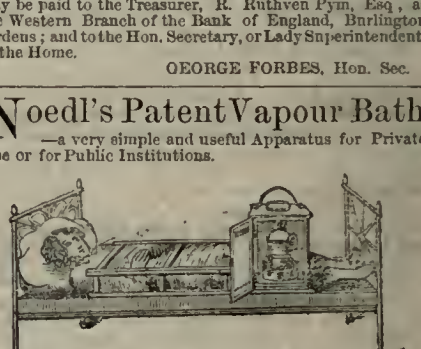
A weekly payment, regulated by circumstances, and varying from 10s. to 40s., must be made by each patient or her friends towards the household expenses, except in the case of those specially recommended by Life Governors.

There are 20 beds, 16 of which are appropriated on the above scale of payments to females of a better class than ordinary hospital patients; and four are reserved for poor patients recommended by Life Governors.

Donations and subscriptions are earnestly solicited, and may be paid to the Treasurer, R. Ruthven Pym, Esq, at the Western Branch of the Bank of England, Burlington gardens; and to the Hon. Secretary, or Lady Superintendent, at the Home.

GEORGE FORBES, Hon. Sec.

Noedl's Patent Vapour Bath —a very simple and useful Apparatus for Private Use or for Public Institutions.



Price reduced to Four Guineas, including japanned outer case.

A liberal allowance to the Medical Profession.

Detailed Prospectuses sent on application.

Manufactured and sold by BENHAMS and FROUD, 40, 41, and 42 Chandos street, Charing cross, W.C.

Huxley's Spiral Abdominal BELT, is constructed on a principle which secures the required support, without being liable to displacement, and is invaluable, when properly constructed, in cases of Pregnancy, Obesity, Ovarian Dropsy, &c. When required, it is fitted with Air-pads for Umbilical, Inguinal, and Femoral Hernia, and Band with Air-pad for Prolapsus Uteri and Prolapsus Ani. These goods, in addition to Stockings, Thigh-pieces, Knee-caps, &c., supplied 30 per cent. lower than the prices hitherto charged, every article being of the very best quality.—Measures required: circumference at a, b, c; depth, from a to c.—Priced and Illustrated Catalogues on application to

E. HUXLEY,
12 Old Cavendish street, Oxford street, W.

Burrows and Co., Wholesale WINE MERCHANTS, LIVERPOOL.
Stores: Lime street.
Offices: 54 Duke street.

The Proprietors beg to call the attention of the trade, noblemen, clergy, and the public, to their extensive stock of choice Wines of rare vintages.

Burrows and Co. are not disposed to comment upon the purity of their Wines, which is daily most laudably acknowledged by the public and eminent Medical men of all countries, as the increasing patronage of the highest families in the land is a sufficient guarantee.

They beg to call particular attention to their pure Tonic Wines as being so valuable to invalids and persons of weak stomachs. A sample case containing three full-sized Wine bottles will be forwarded to any address on receipt of Post Office Order for 6s. 6d., or a dozen for 24s. It is a well-known fact that impure and adulterated Wines are the greatest foes to health, producing acidity in the stomach, and debilitating the digestive organs, while pure wines will accelerate the digestive powers, invigorating, strengthening, and bracing the nervous system.

Their Tonic Wine is admitted to be most essential to invalids, both old and young, and should never be absent from the homes of the weak and sickly. Its properties are duly acknowledged and appreciated by the leading men of the Faculty, both at home and abroad.

To prevent imposition, each bottle is sealed with the name of the firm. All orders to be made payable to Henry Burrows.

CLINICAL OBSERVATIONS
ON
CASES OF PYÆMIA:

HOW ARE THEY TO BE GUARDED AGAINST?—IS PYÆMIA ON THE INCREASE?—MR ERICHSEN; MR PRESCOTT HEWETT.

The prevalence of pyæmia in hospitals is a subject full of anxiety to surgeons; peril also as regards a surgeon's fame, say in private practice, in a case of a little sebaceous tumour of the scalp, or trivial incision of skin or fascia, when he does not like to lose his patient or his name; anxiety and mortification very often, as when he finds he has made half of a good cure of such a case, or a case of excision of a knee or elbow, that it ends in pyæmia. The nature of pyæmia is not at all settled amongst surgeons, but its treatment is improved. Mr Arnott and Mr Guthrie, like Mr Rose, very early showed that the particular form of phlebitis from injury of a vein, where there is a tendency to suppuration rather than to adhesive inflammation of the coats, is the most frequent cause of pyæmia. Mr H. Lee has gone farther, and in repeating the experiments of Lebert and others he has shown that the serum of such pus, especially in certain depressed states of the nervous system, is capable of producing the utmost mischief in form of pyæmia. We say, is capable of producing pyæmia, as there is reason to fear this is not the usual mode in which this disease is generated.

Surgery, like many other of the subdivisions of the art Medical, has its changes and fashions. What is practical and useful in one hospital or school, is often put out of the way for what is not practical, but fashionable and profound, in another. The pathological surgeons at present are men of deep erudition; and to show their erudition, in place of giving us practical surgery they offer the public very unpractical pathology; such dim, unreasoning pathology as tells us that growths with cancer-cells are all incurable; that the infectiousness of cancer-poison has passed into a proverb; that pyæmia is, like this infectious cancer-poison, beyond the reach of art; that syphilis is only to be cured, like small-pox, by fresh infection; and a dozen other things of a like kind, that every day's clinical experience in hospitals helps to negative. Those who deny such learned authorities to be surgeons, allow them to be pathologists and microscopists; but this does not get us over the difficulty that they have evidently no acquaintance with things as seen in hospitals.

We have already said, surgery has its fashions; (*a*) but it is curious, under its many guises, how unchangeable is disease. We are no advocates for the "change of type" theory of diseases:

"Quo semel est imbuta recens, servabit odorem
Testa diu."

The words addressed of old to Lollius are miserably true of disease; it remains the same, only altered by associations of early clinical theories. The word "inflammation" in this way has lost all its original meaning: metastatic abscess has not fared much better; it has scarcely gained, under the new word "pyæmia," clearness and utility.

Pyæmia in its treatment is perhaps a more formidable and more frequent disease than tetanus. Both are curable, if surgeons would follow the dictates of old clinical experience. There are no diseases which so test the "stuff of which a surgeon is made," as to whether he is practical or not. A patient receives an injury, or undergoes some surgical operation, very often of a very simple or trivial kind, a fistula to be slit up, a bit of bone to be sawed. He goes on well for a time, but soon there is a fatal "shiver." Probably pus is now on the road to its perfect formation in the blood itself, in consequence of a change in the fibrine, as in the croupous diathesis, actually as a primary affection; there is adynamic fever, and there is oppression. The patient's countenance changes—it may be be but the veriest shadow of a change, but to the eye of the hospital *habitué* that shadow of a change, that emaciation, that cachectic something, is the shadow or mark of Death's hand already passed over his victim. Mr Guthrie, even as early as 1815, though not very erudite in his pathology, describes the disease with his accustomed force and accuracy; and he found on the Continent, where febrile diseases were endemic, this form of constitutional irritation was very great. The stumps opened again and sloughed, and pyæmia was the result.

What the pathologists and museum curators want in every-day, common-place facts, and practical broad inductions, they endeavour to supply by the microscopic and the factitious. Practical surgeons smile at their dreams of infectious cancer-juice, deafness from marriage of first cousins—their doctrines of crasis, syphilisation, and the like. We have seen in hospitals an entire revolution sweep through the once-venerated dogmas of Rokitansky, and now Virchow's star is in the ascendant. Pyæmia raged like a plague in the Russian hospitals at Sebastopol, but was scarcely known in the French hospitals—all due to different schools of surgery, different "fashions" of treatment. Where we want clear light, the theorists, in striving to be frigid but learned on any given subject, analyse, as it were, the clear light of their sunbeam with a prism; they discuss the shades and varieties of pyæmia, or a tumour that ought or might be cancer, and must be malignant, but which Velpeau, or Brodie, or Erichsen, through the unclouded white light of long clinical experience, pronounces to be a tumour non-malignant, though possibly cancerous.

We have been led into this train of thought by some clinical remarks recently made on the nature of pyæmia by Mr Erichsen.

The prevalence of pyæmia in hospitals is one of those things which, as just hinted at, the pure pathologists can always learnedly explain, but never cure; while the disease itself, the simply practical man can nearly always roughly cure, but he does not care very much to explain. We do not seek to explain this "discordia concors," nor seek to discover the occult reason why at one side of this question we should be inclined to place such hospital-surgeons as Mr Erichsen, Mr Prescott Hewett of St George's, Mr Paget, Mr H. Lee, Mr John Adams; and on the other side, M. Pirogoff, and an equal number of learned surgeons picked out of our own Pathological Society Committees: but every one much accustomed to London visitors and London hospitals must in some hospitals look on pyæmia or phlebitis with much less fear and trembling, and very differently from what he would look on this disease in other hospitals much given to Pirogoff fashions. Pyæmia is no doubt more common in operations on the cancellous tissue of bones; but we have known it to arise after scarlatina or typhoid fever, a bad gum-boil or simple gonorrhœa!

Mr Erichsen, on a careful review of the subject, is of opinion that pyæmia is a very old disease; it was quite as prevalent, if not more so, thirty years ago, as it is this year or last year. Many of the low irritative fevers, congestive slow inflammations, metastatic abscesses, &c. then described in hospital-books were all pyæmia, according to his experience; many bad cases of this kind amongst his notes so far back as 1840, he now thinks, on reading them over again, were cases of what is now known as pyæmia.

Professor Carswell was the first person he recollects using the term in London. The utmost obscurity rested on the subject then; but now he believes it is well established, that deficient ventilation, overcrowding in hospitals, and *deficient or improper food*, are the leading causes of this disease. We have made it a point to inquire by letter of all the leading hospital surgeons of the three kingdoms also as to whether pyæmia has anything to do with anæsthetics: all with one voice say the idea or "fashion" as broached recently is perfectly ridiculous. (*b*) There is no doubt that puerperal fever is carried about by surgeons themselves!

An opinion is very strong in hospitals that pyæmia is sometimes endemic; and probably, like erysipelas, or this one form of puerperal fever (another word for pyæmia and phlebitis), in certain patients predisposed by kidney or other malady, the disease of pyæmia may be carried about by pupils, house-surgeons, &c. going directly from dissecting-rooms to their work as dressers. Such students, as observed by some, commonly administer chloroform in the wards; and in this way, as illogically observed by Mr Syme, chloroform gets all the credit of the pyæmia. In clinical notes of 179 cases of puerperal fever (where there is no doubt of this form of endemic mischief), we find pus in the veins in not less than 117, and pyæmic abscess in joints unmistakable in character in 10! Some observations of the surgeons of St George's, agreeing as they do with those by Mr Erichsen and others by the surgeons of St Bartholomew's, some remarks of Mr Adams at the "London," Mr Solly at "St Thomas's," and some curiously enough of Dr Robert Lee, as to puerperal fever, we may give in the form kindly furnished us by Mr Prescott Hewett. The serious graveness of the subject of pyæmia will be our excuse for this extract.

"Mr Cæsar Hawkins does not think that pyæmia is more common at St George's now than it was some thirty years ago. . . As to the causes, &c. of pyæmia, that it is a most difficult question. But thus much I can say: at times, and for months together, our wards may be perfectly free from pyæmia; and then (without any apparent cause) several cases occur in different wards and different parts of the building at the same time. Operations, compound fractures, injuries of the head, wounds of all kinds, then show the same tendency; but the disease is always found to develop itself much more readily in cases where the cancellous tissue of bone has been implicated.

"Chloroform does not, I think, in any way predispose to pyæmia; at least, we certainly have not found it so at St George's. I may mention in connection with this question, that in private practice I have had several cases of pyæmia in which chloroform had not been administered:

(*a*) A favourite fashionable prescription for gonorhœa, of the *suaviter in modo* kind, endorsed by the initials of an eminent Savile-row Surgeon, is the following: "Mist. mucil., 1 oz.; bals. copaibæ, ½ oz.; acid. sulph. dil., 2 dr; infus. rosæ, ad 8 oz." On the principle of Corydon—*nimium ne crede colori*—the patient is supposed, with this red mixture, not to be too much in a hurry to get well. Some surgeons say balsam and cubebs are an abomination, making the disease worse; still these delicacies are much in fashion, made up with roses.

(*b*) We believe kidney disease has more to do with pyæmia. Amongst recent "fashions," we find an Hospital for "Stone." The present observer is forced to admit that he is not amongst those who seek, on account of journalistic jealousy, to decry such an institution. This hospital, of course, includes as its specialty all the thousand-and-one lurking, insidious forms of urinary diseases. Its motto should be, "Principiis obsta:" stop urinary diseases in their early stage, in the manner so well laid down by Dr George Johnson, Dr Bright, Dr Thudichum, &c., before they have produced that state of the blood that favours dropsy or pyæmia. In a tolerably large experience, of ten years, of the out-patients' department of all our London hospitals—especially the small ones, which, as a royal road to cure all diseases, boast of "free" tickets, night and day, to all comers—we know of no class of diseases so neglected and slurred over as renal diseases. We have several times referred, of course, to the curiously small number of actual cases of "stone" seen in the hospitals, compared to Norwich hospitals, but the terrible mortality attending what are termed our brilliant operations. We wish success to this new institution, if it encourages—as it can scarcely fail to do—a more practical use of the test-tube and microscope; if it prevents the earlier forms or ill-defined milder shapes of Bright's disease from passing into incurable disorganisation, and it lessens the practice of random prescribing, at such "free" hospitals, of strong terebinthinate, acid, or cantharides pills and mixtures, for all such mild forms of urinary diseases, which notably require such remedies rather as warm baths, demulcents, diluents, opiates, &c., in hospital. This institution will meet opposition, as everything good and useful meets mischievous opposition; still the men who are accustomed daily to visit the dead-houses of our large hospitals know what numbers of melancholy cases of diseased kidneys, even in young persons, are found; and we should say that more than half of the adult male applicants at hospitals will be found with kidney disease—probably from drinking inferior kinds of adulterated beer, raw gin, &c. In females, the pressure of the enlarged uterus on the ureters and kidney produces albuminuria, in hundreds of instances overlooked, and is a chief cause of puerperal convulsions, peritonitis, and those states of puerperal fever allied to, if not identical with, the disease we have been considering—pyæmia.

Removal of a sebaceous tumour from the scalp, death from pyæmia! suppuration in the gum, pyæmia, recovery; suppuration in one of the tonsils, pyæmia, recovery; suppuration in the axilla, pyæmia, recovery; suppuration in the cavity of the tympanum, pyæmia, recovery; gonorrhœa, pyæmia, recovery. Such are some of these cases, and the subject, as you say, is of vast importance."

HOSPITAL REPORTS.

GUY'S.—Monday, July 3, 1860.

Stone in the Bladder—Lithotomy—Lateral Operation.—Mr Birkett.

The patient, a man about thirty-eight years of age, a tailor by trade, of spare habits and tolerably healthful, came into hospital from the country some time since. After a few weeks, the lithotrite was applied, and a stone was split, as it afterwards proved, into two unequal parts. Remaining a few weeks in hospital, great irritation ensued, and some fragments came away. By the measure of the lithotrite, the stone was found to be about 1¼ inch in diameter; the fragments caused laceration and injury. To restore his health, which became affected, he went home into the country to recruit. On his return to hospital, after a short time, he became again irritable and feverish, with a dry red tongue and quick pulse, and great constitutional disturbance, under which he at present suffers. The operation of lithotomy was now the only resource, anæsthesia being induced by slow and cautious administration of chloroform: the lateral cut into the bladder was made in the usual way, with a rather large knife. The forefinger and forceps brought away the small segment of the stone, and also, on a second introduction, the larger half, which from its position offered a slight difficulty, the blade of the forceps passing over instead of under the stone. The figure of the stone was diamond or flask-shaped, flattened; in short, it was a miniature model of the bladder flattened, the cervix being elongated, or having a projection, and was 1¼ inch diameter at the widest part, very rough and irregular, with projecting spiculæ. It consisted of a distinct lithic acid nucleus, surrounded by phosphatic crust. It was a neat operation, with little hæmorrhage—quickly performed, considering the irregular surface, roughness of the stone, and the number of fragments to be removed. The patient survived only three days. At the post-mortem examination, an abscess was discovered in the kidney, and a stone the size of an almond was found embedded in the lower extremity of the ureter.

Diseased Ankle-joint—Amputation of Leg at Lower Middle Third, with Lateral Flaps.—Mr Hilton.

The patient, a young woman about twenty-five years of age, in good constitutional health, had diseased ankle-joint, including the ends of tibia and fibula. Suppuration had formed at two or three points, and sinuses established extending to the ankle-joint. After anæsthesia became induced by chloroform, the operation, done in the usual way at the lower middle third of the left leg, gave side flaps which covered neatly the stump. Little hæmorrhage followed: great care taken to detach vessels from nerves in applying ligatures by Mr Hilton.

MIDDLESEX HOSPITAL.—Wednesday, July 4, 1860.

Cataract—Anterior Capsular Cataract—Laceration of Opaque Anterior Portion of Capsule.—Mr Moore.

Opacity of the anterior surface of the capsule of the lens is more common with children, not frequently met with in adults. The patient, a young woman about twenty-five years of age, in good health: first operation. Anæsthesia, induced by chloroform, and dilatation of pupil by belladonna. The needle was introduced through the sclerotic coat in the usual way behind the iris, as for depression; the anterior layer of the capsule of the lens was then freely divided and lacerated, and the needle passed once or twice through its substance by rotatory movement; the lens was brought into communication with the aqueous and vitreous humours, so that absorption or solution of the opaque particles by the aqueous humour takes place. Double convex glasses would, upon cure, be required to compensate for the loss of crystalline lens. In these cases M. Velpeau applies belladonna paint, in the proportion of 3i. of ext. (solution of atropia), diluted with one drachm of water, morning and evening, with intermissions. This practice counteracts many untoward accidents in the progress of cure, from adhesion to the iris of lacerated fragments or opaque bodies. The intermissions are to induce a return of contractility of the iris after dilatation. By this return of contractility, sufficient motion occurs to break adhesions formed, by drawing the pupil backwards and forwards like a curtain. After these intermissions or intervals in the application of belladonna paint, dilatation of the iris is again resorted to by the cautious use of belladonna.

KING'S COLLEGE HOSPITAL.—Saturday, July 7, 1860.

Perineal Fistulæ—Lithotomy—Hare-lip—Resection of Hip-joint.—Mr Fergusson.

Fistulæ in Perineo.—The patient, about thirty-five years of age, emaciated and cachectic, had stricture of the urethra and infiltration of scrotum and perineum from abscess and urinary extravasation. Mr Fergusson introduced a grooved sound into the urethra, and made a median division of the tumefied scrotum about half its length down to and through the perinæum, cutting down to the groove of the sound, dividing the stricture, and opening the urethra upwards and downwards. Upon removing the sound, he introduced a flexible catheter, and then a silver grooved director, through which he further laid open the anterior portion of the urethra from the meatus. Lastly, he introduced a silver catheter into the bladder, to remain in the urethra, being fastened by tapes round a bone collar placed upon the penis, and tied on each side by tapes to the thighs and to a circular abdominal bandage. Mr Fergusson called this the compound operation, and preferred it to laying open the several sinuses.

Lithotomy.

This patient, a boy about fourteen years of age, had been operated upon ten weeks before, and a very large stone extracted, four ounces in weight. The following very extraordinary circumstances are to be related: At the first operation the stone came away in two parts, but was only one stone, of very singular formation. When the two portions were adapted to each other, it formed something like a ball and socket joint, the ball and socket of the stone being perfectly smooth and polished. The socket portion, much the smallest, was extracted first; the other, brought away with some difficulty, was found to be bound down in a cyst to the neck of the bladder by mucous bands, running over a groove extending round the cervix of the *ball* of the stone, as was detected by portions of these bands coming away with it. The boy progressed favourably for a fortnight, and Mr Fergusson conceived he would have a remarkably quick recovery. At evening he became attacked with pain and great uneasiness, to an intolerable degree, about the neck of the bladder, extending all over the abdomen, and Mr Fergusson thought he would die of peritonitis. Upon examination, detected a stone. Mr Fergusson did not think any stone was left after the former operation, and was puzzled to account for its presence. He came to the conclusion that a stone had formed in the lower portion of the ureter, had produced inflammation and abscess, and so become discharged into the bladder. The stone was finger-shaped, and on removal, broken in half by the forceps, having imbedded in its centre a loose, smooth, detached nucleus, enclosed by a stony case or calcareous crust. To explain this state of things, the bladder having a strong tendency to form calcareous deposits, and the stone having, as supposed by Mr Fergusson, passed from the ureter, it became thus quickly encrusted and enlarged, and the outer crust, also very tender, was broken on extraction. Mr Fergusson operated by the lateral section, as he had on the former occasion, and cut in the same line and through the same tissues as before. The operation was performed with wonderful precision and celerity, and could not be excelled, being over, and calculi extracted, in little more than a minute. Mr Fergusson spoke of the lateral section as an old operation in the following terms: "I may be twitted for performing such an old-fashioned operation; it was performed by Cheselden, and is going out of fashion, being superseded by new ones of greater pretensions. I apologise," he said, "for naming this, which perhaps will be excused on my part, as performing a sort of decent tribute to the memory of what will shortly become matter of history—a memorial of what has been done in our day." He wrapt up this sarcasm in a quiet and delicate tone of irony all his own. He further remarked that this operation, performed on children or subjects having small perinæums like the one of to-day, was simple and unattended with danger. (*a*)

Resection of Hip-joint.

The patient, a child about four years old, had been under Mr Fergusson's notice for some time. An abscess formed over the hip-joint, and discharged. A deep-seated sinus was discovered, and on being traced was found to communicate with the joint; the articular cartilage gone, the bone being felt by the probe. Mr Fergusson pushed his finger through the sinus down to the head of the femur, introduced a bistoury, and divided the integuments obliquely backwards on the dorsum of the ileum, thus exposing the head of the bone, and forthwith dislocated it from the cotoloyd cavity, and resected it with saw and nippers. After returning the neck of the bone, and vessels secured, water-dressings were applied. Mr Fergusson, holding up the removed head of the bone, remarked that a great portion of it was gone: it had not come away by bits. This is the process called caries, or necrosis. Physiology does not explain these diseases, and we know nothing about the process of caries. When we say absorption removes it, which is all that is suggested, we must fain be content with this explanation. (*b*) He said, in these diseases Nature had been greatly extolled. He had been much abused for this operation, but had performed it often, and with so much success, he could afford to incur a little abuse. Nor was resection of the hip-joint a more formidable operation than amputation of the thigh or elbow-joint, or so much. He confessed he did not know how to cure these diseases. A farmer boasted of the crop of wheat, the produce of which he spoke of as having grown. True, he sowed the seed; but Nature grew the crop, and in season rendered the produce, which the farmer gathered, and appropriated as his own. In these diseases the Surgeon did neither the one nor the other, and could determine nothing concerning the result; but if Nature be not directed and assisted by the Surgeon in treatment after operation, all will go wrong. She is generous; but if help be not afforded by a proper, straight position, and means to obviate truncal gravitation, which, by movements of the axis of the body to and fro, as with children tossing about, disturbs the limb and prevents a good apposition, the patient will necessarily become victim of deformity.

Hare-lip.

Operated on an infant in the usual way, by needle suture and ligature.

ON THE TREATMENT OF GONORRHŒA WITHOUT SPECIFICS.

By J. L. MILTON.

(Continued from page 238, Vol. XVI.)

I believe, also, that those cases of chronic orchitis and neuralgia which are brought on by gonorrhœa, are much more manageable than has been supposed. Citrate of iron and quinine; a moderate use of mercury and chalk; good diet, with an extra glass of wine, stout, or pale ale;

(*a*) We are informed by Dr Conant, of New York, who is at present in England, that the recto-vesical operation is performed with great success in the hospitals of New York, the lips of the wound being brought together by silver wire sutures, in the same manner as for recto-vesical fissure; this plan preventing extravasation or urinary infiltration within the pelvis, or fæcal matter passing into the bladder, or urine through the rectum. Mr Lloyd, we are also informed, performs this recto-vesical operation for lithotomy at St Bartholomew's Hospital.

(*b*) *Vide* Medical Circular, April 25, 1860, 2nd col., line 23.

plenty of fresh air, and a free use of blisters—will generally effect a fair cure. They will, of course, in some cases only arrest the disease; for no sensible person requires to be told that they cannot regenerate destroyed tissue. Still they open up such an encouraging view, that I protest against removing the testicle until they have had a fair trial, especially as the revelations of Romberg, Civiale, Curling, Brodie, and others, leave no doubt that in many cases the testicle has been excised where a judicious employment of curative means would most probably have rendered any operation superfluous. Besides, it is possible that arrest of the disease by treatment leaves the remaining testicle less liable to take on the same action. In the last case of this kind I attended, I had reduced the diseased gland nearly to its normal dimensions, when some one persuaded the patient to have it cut off—and certainly there was fibrinous deposit enough in it; but three months afterwards, when I again saw the patient, I learned that the other testicle, which up to the time after operation had remained quite sound, was now nearly as bad as that which had been removed.

When *fungus of the testicle* ensues, Mr Symo's plan of paring the edges of the aperture, and then uniting them over the replaced protrusion, generally answers so well, that it would be difficult to find a substitute; and now that this method has received the sanction of Mr Fergusson and other excellent surgeons, it is to be hoped that the old system of castrating patients bit by bit will be put down.

Phymosis and Paraphymosis.—The treatment of these complications may be summed up in a very few words. Phymosis seldom calls for more than suspension of the penis, which may be easily effected by any person possessed of the most ordinary mechanical skill. In the more severe cases, such as are occasionally seen when ineffective attempts have been made to check the disorder with specific medicines, and which never ensue when injections are properly employed, evaporating lotions, containing ether and acetate of ammonia, may be used; I have never seen a case which required more than these. The treatment may be continued just the same as if there were no phymosis, for the prepuce can generally be drawn back so far as to admit the syringe. It is quite a mistake to imagine that this complication proves the presence of an amount of inflammation which would render the use of injections dangerous.

As to *paraphymosis* little need be said. The surgeon should carefully cleanse the penis, and then attempt the reduction of the strangulated part, in which, with a little perseverance, he will generally succeed. Some authors, Fricke among the number, profess to have never failed. I have not been so fortunate, and I have seen much better surgeons than myself who have made ineffectual attempts of this kind. This, however, is not of much importance, as in gonorrhœa, if properly treated, the strangulation, when not neglected, is never severe, and rarely attains such severity as to require cutting of the constricting band. If it should, the evil is easily met.

Balanitis is one of the most easy complications to deal with, although some attempts have been made to bring it within the category of complaints requiring extraordinary vegetable astringents. (*a*) M. Ricord advises cauterization; and if the patient is quite indifferent as to the amount of pain he may suffer, or perhaps rather prefers it, it will answer as well as mild injections beneath the foreskin; but according to my experience it is no better way.

Part III.—On some of the more Uncommon Complications of Gonorrhœa.

We now arrive at the consideration of those symptoms which are more calculated to fetter the surgeon's hands. From their extreme importance, I have been led to illustrate them by a few carefully-selected cases, for which I solicit the reader's most earnest attention, as it is these rebellious forms of disease which have cast so much doubt upon the powers of medicine over this complaint.

Under this head I propose to place all those affections which directly or indirectly interfere with the exhibition of proper remedies. They consist of—1. Strong tendency to *fainting*, and great natural or induced *weakness*. 2. Disposition to *inflammation of the lacunæ* of the urethra. 3. Excessive *sensitiveness of this canal*; strong disposition to *stricture*. 4. Extreme *irritability of the bladder* and rectum. 5. *Perincal abscess*. 6. *Inflammation of the prostate*. 7. Gonorrhœal *rheumatism* or *ophthalmia*. 8. *Hæmorrhagic diathesis*.

1. Fainting from the use of injections.—In speaking of a strong tendency to faint from the use of injections, I allude, not to the mere sense of faintness felt on passing the tube of the syringe down the urethra for the first time, as that is quite a common affair, but to that form where the disposition is so strong and recurs so constantly as to constitute an idiosyncrasy. I have seen it in very strong men.

Case.—An acrobat who had contracted a discharge came under my care. He was a healthy, temperate man, a solid mass of bone and muscle. This energetic method of gaining his livelihood was practised "sub Jove," and he developed his powerful frame to the highest pitch of health and strength it was capable of. Yet this man fainted so suddenly on my attempting to insert a short syringe into the urethra, that he fell like a stone. The insensibility was very prolonged; and he felt so ill after it, that he refused to have any more injections.

The plan in such cases is to give the injection to the patient in a sitting or lying posture. This will overcome the most obtinate fainting, as the following instance may show.

Case.—A very tall, delicate young gentleman applied to me with gonorrhœa. About eighteen months previously he had suffered from an attack, which, with all possible care, was not subdued with copaiba and salines in less than nine months: ever since then the urethra had remained extremely tender, and whenever he had a cold, a drop of pus was seen at the meatus on rising. On inserting the syringe he immediately fainted, and so soon as ammonia was applied to his nostrils the contents of his stomach were discharged; but the impression made upon the disease was so evident, that the patient willingly continued the injections, which were given sitting. At the end of eleven days the discharge was so far diminished that they were given only every second day, and then every third, till the twenty-fifth, which was the last; no discharge having been seen for eight days, yet the faintness was present to the last.

Some months later, during an excursion in Austria, he again contracted the disorder; he was treated with specifics, and derived almost as little benefit from them as before. Soon after his return to England he contracted a fresh infection, and six months subsequently he had another attack. On both these occasions the complaint was removed within a week by means of injections, but the tendency to faint was still as strong as ever when beginning with them. After the last gonorrhœa, I recommended the use of a gum-elastic bougie twice a week. To the very last day of using it, he always averted his sight from the instrument, feeling sure that he would turn faint if he looked at it. This treatment, I may observe, answered the end in view: the patient, though he was soon as imprudent as ever, contracted no more gonorrhœas.

Amongst numberless instances, I might point to this case as strong evidence of the superiority of injections over any other treatment. The patient was in easy circumstances, rested as much as he liked, consulted the first surgeons, and yet on one occasion his disorder, when treated by medicines, lasted nine months, and in another three, leaving each time the urethra very tender and irritable; whereas, when met with injections, one attack was cured in eleven days, one in four, and one in five. These cures, too, were more perfect; and that the disparity was not due to a decline in the virulence of the disorder, is shown by the third outbreak lasting so much longer than the second.

24 Castle street, St Martin's-le-Grand.

OUR NOTE BOOK.

QUININE IN UTERINE HÆMORRHAGES.

In the March number of the 'Charleston Medical Journal and Review,' Dr J. S. Rich, of Georgia, reports several cases of protracted uterine hæmorrhage of an alarming character speedily relieved by the use of quinine, after the failure of all other known means. The following are his favourito methods of administration:

" ℞.—Sulph. quinine, 5j.
Sulph. ferri, 5j.
Mucil. gum Arabic, q. s. ut ft.
Pillulæ, No. xxx.

' ℞.—Sulph. quinine, 5j.
Sulph. ferri, 5j.-ß
Gum terebinth. 5j.

M. ft. in mass. et div. in pillulæ, No. xxx. S.—Two to be taken morning, noon, and night."—'American Medical Monthly.'

PUERPERAL CONVULSIONS CURED BY REPEATED COMPRESSION OF THE CAROTID ARTERIES.

A woman aged twenty-one, residing at Gourdon (Lot), had reached the end of the eighth month of her first pregnancy, and was in perfect health, when on the 25th of last April, after having worked all day, as usual, in a sitting posture, she stumbled as she rose from her chair, and fell backwards, inflicting at the same time a severe contusion upon the region of the sacrum. An hour after the accident, the signs of premature labour became manifest; a midwife was summoned, natural parturition took place, but scarcely had delivery been effected, when violent convulsions set in.

A physician, who was then called in, prescribed leeches to the temples and mastoids, and mustard-poultices to the lower extremities; but instead of being relieved by these measures, the convulsive attacks returned with increased violence, and with so much rapidity as to be almost incessant, being only separated by short intervals of deep coma. When I visited the woman next day, the 26th, her condition was unaltered, and the fits had then persevered with obstinacy for eighteen hours. The sufferer's vigorous constitution, her full, throbbing pulse, the congestion, and turgid state of the face, seemed to indicate the propriety of copious bloodletting, which I accordingly performed, prescribing also the following mixture, to be taken in table-spoonfuls every hour.

℞—Aq. distill. . . 3 oz.
Liq. ammoniæ . 120 minims.
Syr. minthæ . . 1 oz.

This line of treatment proved as unavailing as that which had been previously instituted. It then occurred to me to have recourse to pressure on the carotids, according to the method of M. Blaud, of Beaucaire, which consists in applying compression to both arteries simultaneously, either by flattening them with the thumb and middle finger against the sides of the larynx, thus approximating them to each other, or by directly forcing them back with the finger and thumb against the anterior aspect of the vertebræ. I adopted the former procedure, and I had the happiness to find that, during my very first experiment, the paroxysm became less violent and shorter. The double pressure exercised upon the blood-vessels of the neck soon enabled me to master the subsequent attacks, and to check them suddenly whenever the convulsive fit appeared on the point of occurring. I must, however, acknowledge that, if I was at length successful in conquering the convulsions, the most formidable I had ever witnessed, it was not without difficulty, for I had to resort to compression not less than 150 times during a struggle of twenty-four hours. I should also add that the unconsciousness and coma persisted many hours after the cessation of the fits, and yielded at last but to the combined action of two large blisters applied upon the legs, and of five grains of calomel in three doses, which were taken at intervals of half an hour.

I am utterly ignorant of the cause of these inexplicable convulsions, and refrain from idle disquisition on the subject. But I must lay stress upon a practical point, which appears to me of paramount importance, viz., the result which was effected by reiterated and persevering pressure upon the carotids. In the case of similar attacks, for which, as M. Pajot recently remarked in a lecture at the hospital of the School of Medicine, venesection alone has always proved unavailing, the method which I found successful should be without delay resorted to, and I am confident that it will render the greatest service when other remedial agents have failed. Inhalations of chloroform at the beginning of the paroxysms, and renewed whenever the convulsions return, have also been found beneficial. MM. Pajot and Blaud

recommend them in preference even to bloodletting. Both chloroform and pressure might be simultaneously employed. Thus the practitioner will at least be supplied with some means of treatment for a morbid condition which has hitherto baffled the most ingenious combinations of the therapeutist.—Dr Labalbary in the 'Journal of Practical Medicine and Surgery.'

THE SPIRIT OF THE PERIODICALS.

The 'Lancet' opens with the Lectures on *Paralysis of the Lower Extremities* by Dr C. E. Brown-Sequard. We quote the following conclusions on myelitis :

"To understand well what we have to say of the symptoms of inflammation of the spinal cord, it is important to bear in mind the following facts :—

"1st. That the grey matter of the spinal cord in its normal condition is not at all excitable, and that irritations upon it are not followed by sensations or movements ; while, on the contrary, when inflamed it is excitable and able to give all kinds of sensations, and to produce cramps or partial convulsions.

"2nd. That the white matter of the spinal cord is not composed of motor and sensitive fibres coming from or going to the brain.

"3rd. That a pressure upon the spinal nerves, or upon the spinal cord, able to produce a paralysis accompanied by cramps, may either produce anæsthesia or not, while it causes various sensations.

"It is not our intention to speak here of the acute myelitis accompanied by fever, as in almost all cases of that kind there is at the same time an acute inflammation of the spinal meninges, and also because we only intend to show what the symptoms are in those cases of paralysis of the lower limbs of long standing that depend upon a chronic inflammation of a part of the spinal cord in the middle or lower parts of the dorsal regions.

"The characteristic symptoms of this local myelitis are :

"1st. A constant pain at the part of the spine corresponding with the upper limit of the inflammation of the cord.

"2nd. Whether a constant pain exists in a very marked degree or not, it is almost always found that pressure upon the spinous process of the vertebræ (sometimes even a slight one), when made at the upper limit of the inflammation, causes an acute pain.

"3rd. The passage of a sponge, filled with warm water, along the spine, gives a normal sensation of heat in all parts above the seat of the inflammation, but a burning sensation at its upper limit.

"4th. The passage of a small lump of ice along the spine gives the natural sensation of cold everywhere, except at the level of the inflammation, where the sensation is that of burning.

"5th. Most patients complain much of a sensation as if there were a cord, or some other ligature, tied round the body, at the limit of the paralysis. In a few patients there is but a very slight sensation of that kind. This symptom seems to exist in all cases of myelitis, and to depend chiefly, but not entirely, upon a state of cramp of some part of the muscles of the abdomen or the chest.

"6th. Various sensations, resembling very much those which follow the pressure upon a nerve, such as formication, pricking by pins and needles, and sometimes a feeling of burning or intense cold in the feet, legs, and thighs, less frequently in the abdominal walls. These sensations exist with as much, if not with greater violence, in parts deprived of sensibility, as in parts which are still sensitive. They originate from the irritation of the grey matter of the spinal cord, and are referred to the limbs and abdomen, just as the pressure upon a nerve produces sensations in its ramifications. They are important indications of myelitis.

"7th. Cramps in the feet or calf of the legs are very frequent. There are more or less of them in every patient. Frequently there are cramps also in the large abdominal muscles, besides the circular and linear cramp that gives the above-mentioned feeling of tightening. A cramp limited to a part of one or several abdominal muscles may remain almost permanently for days and weeks, forming a kind of lump, which may be mistaken for a tumour.

"8th. Whether myelitis exists only in a small zone of the spinal cord, or occupies the whole of the dorso-lumbar enlargement, the paralysis of movement exists in all the parts of the body that receive their nerves from the portions of the spinal cord that are below the upper level of the inflammation. The degree of paralysis varies extremely in different patients, but it is nearly the same in the various muscles of the lower limbs in the same patient.

"9th. Paralysis of the bladder and of the sphincter ani is almost always present in inflammation of the lower part of the dorsal region of the spinal cord ; but when the seat of the inflammation is higher up in the dorsal region, there is rather a spasm than a paralysis in the sphincters of the bladder and anus. Often then there is retention of urine, owing to the paralysis of the bladder while the sphincter vesicæ is more or less in a spasmodic state.

"10th. One of the most decisive symptoms of myelitis is the alkalinity of the urine. There is no patient attacked with myelitis in the dorsal region of the cord whose urine is not frequently alkaline. At times, especially after certain kinds of food, the urine is acid, but the alkalinity soon reappears.

"11th. Anæsthesia, or at least a diminution of sensibility, always exists in myelitis, except when the grey matter is not the seat of the disease, which is very rare. Usually, the inflammation begins in the central parts of the grey matter, and then a diminution of sensibility is one of the first symptoms. That peculiar kind of sensibility of muscles which serves to direct our movements is especially impaired in the very beginning.

"12th. When the dorso-lumbar enlargement is inflamed, reflex movements can hardly be excited in the lower limbs, and frequently it is impossible to excite any. On the contrary, energetic reflex movements can always be excited when the disease is in the middle of the dorsal region, or higher up."

Mr Braxton Hicks contributes to the same journal what is called a *New Method of Version in Abnormal Labour*. We extract the description of it :

"The method I have found successful, and very easy of application, is conducted thus :—We will suppose the simplest condition, a case where the uterus is passive, membranes unbroken, the liquor amnii plentiful, the os uteri expanded sufficiently to detect the presentation, which is cephalic, and in the first or fourth position (occiput to left side) ; the patient is in the ordinary position, the trunk curved forwards as much as possible, to relax the abdominal muscles. Introduce the left hand, with the usual precautions, into the vagina, so far as to fairly touch the fœtal head, even should it recede an inch. (This generally requires the whole hand.) Having passed one or two fingers (if only one, let it be the middle finger) within the cervix uteri, and resting them on the head, place the *right* hand on the *left* side of the breech at the fundus uteri. Employ gentle pressure and slight impulsive movements on the fundus towards the right side, and simultaneously on the head towards the left iliac fossa. In a very short time it will be found that the head is rising, and at the same time the breech is descending. The shoulder is now felt by the hand in place of the head ; it in like manner is pushed to the left, and at the same time the breach is depressed to the right iliac fossa. The fœtus is now transverse ; the knee will be opposite the os, and, the membranes being ruptured, it can be seized, and brought into the vagina.

"Having now the labour at command, the case must be treated according to the circumstances which called for turning. In obedience to the law above stated, when the fœtus is placed transversely, a slight impulse will determine the final position of the head. When the leg is seized, therefore, it is advisable to place the right hand beneath the head in its new position on the left side, and gently press it towards the fundus. The same law renders it very easy to convert the cephalic, shoulder, neck, or even natural transverse, into a breech case. In either of these conditions it is merely necessary to push up the head, and, removing the left hand from the vagina without bringing down the knee or foot, place it on the breech in the right iliac fossa, so as to depress it into the cavity of the pelvis. No extra force should be used, for it will be found to obey a very 'gentle persuasion.' Indeed, the change is completed sometimes spontaneously, and the foot is at hand before it is expected. The breech now presenting, it is advisable to retain it till labour is fairly set in, by a firm bandage placed externally, and, should it be required, a pad on either side of the fundus. It should now be treated as an ordinary pelvic presentation.

"We have in the above case supposed the fœtus to have been placed with the back to the left side (first and fourth positions). Should it, however, be certainly ascertained to be placed in the opposite direction (second and third positions), the only alteration required is to make the pressure and impulses in the opposite directions, following the same rules. But suppose the exact position cannot be made out : in that case it should be considered as being in the first and fourth, and treated as above directed ; and for the following reasons :—1st. The fœtal head presents in that position (back to left side) in from sixty-five to eighty per cent. ; consequently the practice would be correct in that proportion. 2nd. Should the child be turned over on its back, one side is almost certain to be the most dependent ; consequently a knee or a foot will be within a finger's reach. Should the lower limbs not be near, it can be readily converted into a breech case, whereby the foot or breech will be close to hand. Suppose, again, the liquor amnii has escaped—although it certainly does make the operation more difficult, still, as the cases to be quoted will show, it is easily managed even then, the principal impediment being the activity of the uterus ; should that render it troublesome, suspend it for the moment, either by chloroform or opium, and I believe the escape of the waters will be found to be no objection to operation. With respect to other conditions which may retard or interfere with it, they must be treated in the same manner and on the same principles as apply to the ordinary method, and require the same judgment on the part of the operator.

"In considering, secondly, the general advantages of this operation over the ordinary method, I disclaim all intention of unnecessarily depreciating an exceedingly valuable and ancient operation—one which has saved numberless lives, and one with which, at present, we cannot dispense. Still, if it can be shown that in a considerable number of cases requiring version, the operation can be accomplished as quickly, or even more so, without the necessity of introducing the hand into the uterus, with the exception of one or two fingers passed a little way into the os, I am sure that such a modification of this more or less hazardous operation will recommend itself without any panegyric on my part. For in that case it will readily be perceived that we shall avoid—

"1. The addition of the hand, and perhaps arm, to the uterine contents ; and the irritation, present and future, caused by it.

"2. Entry of air within the uterine cavity.

"3. Liability to rupture of uterus.

"4. Much of the pain and distress felt in the ordinary plan.

"5. The removal of the coat, and baring the arm of the operator ; and, as a minor consideration,—

"6. The fatigue and pain endured by the operator while the hand is in utero.

"I think the removal of these objections a matter of considerable importance, even if option were given us in all cases ; but more especially so when we add to this the power the plan I have suggested gives us—namely, of being enabled to turn under circumstances totally impossible by the older method. I feel confident that all impartial practitioners will, after a fair trial, adopt it—I will not say to the total exclusion of the other, but certainly upon every possible occasion in preference ; for there is one thing upon which much stress can be laid, which is, that the unsuccessful attempts to accomplish the new method, instead of increasing the difficulty of delivery by the older plan, tends rather to make

the latter more easy; at any rate, the fœtus can easily be returned to its original position.

"Prof. C. Esterle has shown great skill and patience in endeavouring to detect during the seventh and eighth months of pregnancy the position of the fœtus, and deserves great praise for practically showing the possibility of version at that time; but as such opportunities are rarely to be found in ordinary daily practice, and as it scarcely can be expected his skill and experience are to be met with except in such as devote their time especially to that subject,—and as, coupled with other reasons, it is a practical fact that the majority of the malpresentations and complications of labour do not come to the knowledge of the practitioner till labour has set in, or till, as in hæmorrhage, active interference is necessary,—I think that I am not overrating the value of the above easily-applied and safer method of version; for the finger inside the cervix gives a sure indication as-to progress of the pressure on the breech above.

"It may be noticed as an advantage that the membranes need never be ruptured, as was generally practised, though not always, by the older method.

"The third point I proposed for consideration was the question—To what cases is the above method more peculiarly applicable, and to what conditions is it exclusively so?

"From the foregoing remarks, it will be readily seen that it can be applied at the earliest period a malpresentation is detectable. As soon as the finger can enter the cervix, so soon can version be performed, converting all forms into breech presentations. In malposition of the head, perhaps it may be found capable of improving its position without having recourse to complete podalic version; in puerperal convulsions, diminishing the great risk in such cases from the addition of the hand to the contents of the uterus; in narrow brims, when version is decided upon, it will save the pressure upon the os uteri against the projecting parts of the brim. To these points I shall allude in a future communication, and shall for the present confine myself to the advantages this method gives us in *placenta prævia*—at least, in every form of partial insertion. I have as yet had no opportunity of testing its applicability in absolutely central insertion, and perhaps we can scarcely hope for any peculiar advantage in that condition, which becomes so formidable if the os continue undilated. Although in most writings it is said the hæmorrhage which in these cases has already occurred is generally sufficient to dilate the os, still many will present such a prolonged rigidity of that part, that death may take place before entry of the whole hand can be effected; and it has so happened that this form has in my own experience been by far the more frequent. These cases are the more serious because of the difficulty of obtaining a firm compress on the bleeding part. The contracted cervix generally has been seen where the hæmorrhage has begun some time before the full term (at the seventh or eighth month), when the lower portion of the uterus has not fully expanded.

"The following cases will illustrate the advantages of the method above described, whereby, as soon as the finger can enter the os, it is practicable to bring down the knee or foot, and by that means have the command of the hæmorrhage and labour at the same time; for the conical form of this natural plug is just suited to the requirements of the case. By gentle traction on the limb, the os is completely and circularly filled up; and as it dilates, the size of the plug, as it descends, increases, whereby a continuous pressure can be kept up, its force varying at will according to the requirements of the case. Having then secured this plug, by keeping hold of the limb, we can afford to wait till, on the one hand, the system has rallied to bear the completion of the labour; or till, on the other, the os has dilated to permit the evacuation of the fœtus. Thus we gain an early command of the labour at a time long prior to that permitted us where the hand must be introduced; while we gain much valuable time, save much blood, and husband the patient's strength. But, having so done, my opinion is, that hastening delivery would be highly improper. The only thing that could justify us is the suspicion that hæmorrhage was going on internally. As far as I have seen, this has not occurred; nor is it at all probable, in this condition of cervix, which is pressed upon by the plug for some distance—at least, far above the source of the bleeding."

We need not transfer the cases.

Mr Baker Brown also contributes some Reports on certain *Diseases of the Rectum*, the symptoms of which have been ascribed to uterine disease. We quote one of the cases as representative of the six reported, and as indicative of the character of disease described:

"Case 1.—L. P.——, aged twenty-five, single, admitted into the London Surgical Home Dec. 22, 1858. She complained that she had suffered for a long time from heat and pain in the womb, with pains in the back, and a general feeling of uneasiness in her bowels. She looked ill and worn, and was suffering much from dyspepsia. She had been treated by leeches to the uterus, for dyspepsia, and for the uneasiness in her bowels, but without deriving the least benefit. On examining the uterus, no disease could be found; menstruation was regular; there was slight leucorrhœa. On inquiry if she had more pain at the time of, or after, an action of the bowels, she replied, 'Yes, alwaya; that then she had a sharp shooting pain darting through the womb, and that she was obliged to lie down because the pain and uneasiness were so great in her bowels; in fact, that she dreaded going to the watercloset.' On passing my finger into the rectum she complained of acute pain, and I found a deep fissure just within the sphincter, and opposite to it a small pendulous polypoid body, the pea-like end of which dropped into the fissure.

"*Treatment.*—A dose of castor oil was ordered early in the morning on the following day, and after it had acted freely the rectum was well washed out with warm-water enemas; the fissure was then divided by Copeland's blunt-pointed straight bistoury, the polypus tied, and the rectum plugged with lint soaked in sweet oil. Two grains of opium were given, and generous diet ordered.

"Dec. 25th.—The bowels were opened by a castor-oil enema; afterwards the nurse applied sweet oil on her finger to the whole cut surface, and repeated it once daily.

"Jan. 6th, 1859.—Discharged, quite cured. I have heard of her since as continuing perfectly well.

"*Practical remarks.*—This case well illustrates the proposition which I have just advanced. I would also wish to observe that a very large number of fissures of the rectum are produced by these little polypoid bodies, as they will be found in almost every case if carefully sought for. It will be observed that the dressing of lint and oil was never repeated. This has been my invariable practice for the last twenty-five years, having been taught the great practical fact by my esteemed friend, the late Dr Copeland, that it is never necessary to interfere with the parts by the painful process of reintroducing the lint, if care be taken that the first dressing be left in for forty-eight hours; after that time there is no fear of union by first intention, but, on the contrary, a healthy granulating process is set up, which continues till the end."

The Lectures on *Experimental Pathology* by M. Claude Bernard are continued in the 'Medical Times and Gazette.' The special subject of the lecture is the analogy existing between the action of morbid causes and that of poisons. We quote some paragraphs:

"Our purpose is, therefore, to examine, in the natural order of succession, the phenomena which take place within the living body, when foreign substances have been ingested, in order to learn the mode of action which enables it to produce baneful or salutary effects (as the case may be) throughout the whole system. We have found, for instance, that woorara paralyses all the motor nerves, puts a stop to all motion, suspends the act of respiration, and thus brings on suffocation. The practical result is, that by artificially insufflating air into the lungs during a sufficient length of time, the animal is kept alive till the poison has been eliminated, and all danger is past; now, the same takes place with all poisonous substances which do not produce actual disorganisations of the tissues: strychnia is in the same case as the former poison, for, if all the external excitement which perpetually provokes reflex action, and thereby brings on convulsions, which end in death—if all these irritating causes, which inevitably act upon the animal left in the open air, are cautiously removed, all danger is avoided, and the animal slowly recovers, if the dose of poison has not been too large. Place a frog under a glass bell, in a cellar, after poisoning it with the alkaloid, if left there during a sufficient time, the animal is found to recover perfectly; while another frog, *cæteris paribus*, rapidly dies in violent convulsions, when repeatedly excited. The effects of cold may also be brought forward as an instance; when moderate, they benumb, but do not freeze the tissues: a frog's heart may be brought to stop under the influence of cold; but give it a more favourable medium, and it will recommence beating: if frozen, however, there is an end of all vital properties, its tissues having been disorganised.

"Such is the process of reasoning brought to bear upon physiological questions; an entirely similar method ought to be followed in clinical researches, for nothing resembles so much the action of poisons as that of morbid causes of an ordinary description: the analogy holds good even in those cases in which the disorder is wholly local, and does not end in death. Corvisart, in his celebrated work on Diseases of the Heart, relates the case of a young girl who, in order to commit suicide, swallowed a very large dose of arsenic; some symptoms of poisoning followed, but the patient recovered, and, several months later, died of consumption. In making the autopsy, a large pseudo-membranous cyst was found in the stomach; within this cyst was enclosed a solid mass of arsenic, which might have sufficed to poison nine or ten persons; this was the residue of the primitive dose, a very small portion of which had been absorbed, while the remaining part, incased in this accidental cavity, rested within the stomach without producing other effects than those of an ordinary and inoffensive tumour. Now, if the cyst had been a spontaneous morbid production, instead of resulting from the ingestion of a foreign substance, the consequences would have been identically the same, unless inflammation, suppuration, and resorption had taken place within the tumour.

"If we examine some of the diseases which most frequently produce death, we shall equally be obliged to have recourse to general effects, in order to explain the mechanism through which the ultimate result is attained: numberless patients die of peritonitis, and in a very short space of time too; how does this take place?—for peritonitis, at first sight, does not seem to interfere with any of the higher functions of life. Inflammation of the lungs or pleura frequently proves mortal in a few days; and in such diseases the respiratory functions are of course impeded; yet mere asphyxia is evidently not the cause of death in acute cases of pneumonia; and, in affections which rapidly prove fatal, the animal, although deprived of food, cannot evidently be supposed to die from mere inanition in so short a space of time. It therefore becomes necessary to proceed to a rational investigation of all the diseased tissues, in order to ascertain the mechanism through which death has been produced: both nerves, muscles, glands, and other tissues—both the solids and liquids of the body require to be examined. If, for instance, the substance of the liver is submitted to chemical analysis, it is found to contain no more glycogenic principles; the total disappearance of which is, in our opinion, one of the most ordinary causes of death; for animals kept fasting for several days together still retain a certain amount of sugar in the blood. It therefore seems that life may be extinguished in two different ways: firstly, by the introduction of deleterious principles into the blood; and, secondly, by the total absence of indispensable elements in that fluid. From such instances, it is hardly difficult to judge what degree of scientific accuracy we may expect to find, in ordinary post-mortem examinations: local lesions are exclusively sought for, while the general disturbance passes unperceived; and, even supposing its existence to have been suspected during life, how difficult it becomes, in the human subject, to ascertain the fact after death! Twenty-four hours must have elapsed before we are allowed to touch the corpse: now, although in animals recently slain the natural properties of healthy tissues persist during a

certain space of time, we are perfectly aware that, after a few hours, they are no longer to be found: such, for instance, is the case with respect to the galvanic excitability of muscles and nerves in birds and mammiferous animals. If, therefore, the effects of woorara, digitalis, and other poisons, which act upon these very tissues, had been exclusively studied in the human species, we should never have been able to ascertain by comparison the precise nature of the injury."

A Clinical Lecture by Mr Le Gros Clark is published in the same journal, to which also Dr James Arnott communicates an article on the *Treatment of Rheumatic Affections* by congelation. He thus reports a case:

"A woman, between fifty and sixty years of age, employed as a cook in a gentleman's family, was, after an exposure to cold and dampness, affected with pain, swelling, heat, and slight redness of both ankles. She walked with great difficulty, and her sleep was much disturbed by an increase of pain during the night. There was no fever, nor other symptoms of constitutional disturbance. I saw her nine weeks after the commencement of the disease, had learned that the colchicum, iodine, quinine, and other remedies, which she had taken, had proved of no avail. On the contrary, her sufferings had increased, and it was proposed to send her into the country for change of air. On the 26th of February last, recourse was had to congelation. About three-quarters of a pound of ice, enclosed in a small canvas bag, were, by means of a flat iron, broken into a fine powder, and rapidly mixed with about half their weight of common salt. The mixture was then poured into a piece of gauze, and applied to both sides, successively, of each ankle, while the foot rested on the edge of a basin. The gauze bag covered a circular space of skin of between three and four inches diameter, and was kept in contact with it for about six minutes. During the last half of this period, the skin was white, hard, and insensible. When this congelation had ceased, a small quantity of powdered ice was placed across the ankles in order to prevent the smarting which would have otherwise accompanied the returning sensation, and the patient was desired to keep the ice applied for a quarter of an hour, or longer than this, if the smarting should return on its removal.

"Circumstances prevented my seeing the patient until the third day afterwards, when she expressed in very energetic terms her thankfulness for the relief which had been afforded. There had been no return of pain after the congelation, and consequently no interruption of her rest at night. All that she now felt was a sense of stiffness of the joints. There had been heat and tingling of the skin, particularly on the second day after the frigorific had been used; but this she had quickly removed by sponging the part with iced water. As the congelation had not been kept up so long as it sometimes is, there had been no vesication produced, and, consequently, none of that tenderness of the skin which follows vesication. The stiffness and weakness of the joints continued for some time, but not in such a degree as to prevent her walking; and had the disease been of shorter duration, these effects of it probably would not have existed. On the other hand, when the disease has continued for a very long period, and produced organic change in the joint, though all suffering may be removed, the stiffness will probably be permanent.

"The congelation did not last four minutes; for being desirous to avoid vesication of the skin, I should have preferred repeating the milder application to causing this annoyance from one of greater duration. In determining the proper period during which the part should be kept congealed, it is necessary to take into the account the strength of the frigorific mixture employed. A large quantity of well-pounded ice and salt, applied when the materials are acting strongly on each other, will produce a more deeply-penetrating and a more lasting cold than a smaller quantity not so well prepared. The only instance which I have known of healing by the first intention being impeded after an operation performed under congelation, proceeded from its having been too long continued when produced by a very powerful frigorific; but even under these circumstance there would probably have been no impediment, had an appropriate mode of dressing the wound been adopted.

"To the prevalence of two errors must the imperfection in the treatment of rheumatism be chiefly attributed. One of these is the undue influence which certain theories of the nature of the disease have been permitted to exercise; the other is the false view that has been taken of the disposition which rheumatic inflammation has to extend from one part of the fibrous system to another, or of what has been termed metastasis.

"The theory of the nature of acute rheumatism at present in vogue is a plausible one, but it ought not to be relied upon to the degree that would render those lessons of experience which are apparently contradictory to it less impressive. That an acid exists abnormally in the blood, there can, reasoning from chemical analysis alone, be little doubt; but whether this acid be the cause of the disease, or only one of its numerous effects, or what the importance of each of these effects may be, are points to be yet ascertained. What has been termed by the late Dr Todd the eliminating mode of treatment, and which mainly consists in the administration of large doses of some alkaline substance, accords with this theory; but the well-attested advantages proceeding from what are known as the bark, opium, and lemon-juice modes of treatment are adverse to it. So, also, though the supposed common causes of rheumatism, cold and moisture, are in favour of the idea that the emunctories of the skin are closed by their influence, the immediate occurrence of this disease, and of the analogous disease, gout, after sprains, wounds, and urethral irritations, would lead to a different conclusion. One of the most severe attacks which I have met with of rheumatic fever immediately followed the bite of a horse; and one of the severest attacks of gout was the consequence of sudden dilatation or rupture of stricture of the urethra.

"The common opinion respecting the metastasis of these diseases is founded partly on imperfect observation, and partly on imperfect theory. Inflammation of the heart sometimes precedes inflammation of the joints in rheumatism; and is so common an event during the continuance of the disease, that Dr Watson has only known two cases of rheumatic fever occurring previously to puberty in which the heart was not affected. That rheumatic inflammation of the heart often takes place about the same time that inflammation ceases in a joint, is indisputable; but this coincidence no more shows the connection of cause and effect, than the occasional coincidence of dreams and events shows that dreams are prophetic. Rheumatic inflammation extends to various parts of the fibrous system, just as common inflammation attacks successively various parts of the respiratory mucous system; and, doubtless, the part last affected may act in some degree as a counter-irritant in removing the inflammation previously existing in other parts. If it be true (and the idea is, to a certain degree, supported by the pathological researches of Dr Garrod) that the articular inflammation is produced by the deposition of a *materies morbi*, it must follow that, as inflammation so produced would impede this secretion or deposition, whatever is calculated to moderate or remove it, will, instead of repelling the poison into the blood, not only promote its deposition in the joints, but, by preventing a febrile disturbance of the system from the violence of the local affection, facilitate its excretion by the skin and kidneys. If we take it for granted that rheumatism is a blood disease, we must admit, with Dr Graves, that the poison, in certain favourable conditions of the system, may pass off by the emunctories without exciting local disturbance—just as electricity may pass from the clouds to the earth without injury to buildings on its surface."

Mr Hulme reports an interesting case of *Malignant Disease of the Right Eyeball*, supposed to have been congenital; and Dr Osborne contributes an article founded on a case of *Poisoning by Strychnia*, which we extract:

"Prior to the discovery of Marshe's test for the detection of minute quantities of arsenic in organic mixtures, many cases of arsenical poisoning, probably, occurred which were never brought to light; but whether cases of poisoning by strychnia have been overlooked for want of a delicate process for its extraction, or whether errors in diagnosis occurred, I cannot venture to assert. It is possible, however, that there was a greater difficulty in procuring strychnia by the public formerly than now.

"A few months since a case of poisoning by strychnia occurred in this town, and Mr Lawrence, who was called in, made a correct diagnosis of the case, as it ultimately proved to be by the result of the analysis which I was requested by that gentleman to undertake.

"Mr Lawrence kindly invited me to the post-mortem examination which he performed, and we placed in three jars, the stomach with its contents, a portion of the small intestines, including the duodenum, and a portion of the liver. By keeping the parts separate from each other, we prevented the possibility of transferring any portion of the poison from one part to another. On opening the stomach, about eight ounces of fluid, mixed with a quantity of partly-digested food, was present. The mucous membrane of the stomach presented no appearance of congestion, as is usually observed when death takes place after a full meal; but it exhibited a pale colour, except at the pylorus, which was congested.

"In conducting the analysis I was kindly assisted by Mr Lawrence, and proceeded at once to search for strychnia. One-half of the contents of the stomach and the organ itself were submitted to the chloroform process, as recommended by Messrs Rogers and Girdwood, using sulphuric acid for the solvent. The duodenum and its contents were submitted to the same process, using hydrochloric acid for the solvent; but so much colouring matter was taken up by the acids, that a further process was necessary ere the strychnia could be obtained sufficiently pure for the application of the colour tests. Owing to the difficulty and time occupied in getting rid of the organic matter, I used acetic acid for the solvent for the other half of the stomach and its contents; also for the liver, substituting ether and potash for ammonia, as recommended by Dr Letheby, when the strychnia was obtained at once in a state of purity for the application of the colour tests.

"After washing the potash solution with ether it was treated with chloroform, and the strychnia obtained equally pure by that solvent, thus showing the superiority of acetic acid over the two former acids, at least in the case under consideration; and I trust the observation affords a sufficient excuse for publishing the process which I found to be the most direct for obtaining a satisfactory result.

"It may be necessary to state that in the alcoholic stage of the process we were surprised to find the extract only slightly bitter to the taste (a small quantity only being applied to the tongue), and in order to prove whether the strychnia was taken up by the sulphuric and hydrochloric acids, we resolved upon trying its effect upon animals. For this purpose a kitten was procured, and a small quantity of the fluid extract (deprived of spirit) administered. The first symptom observed was that the hair of the animal stood on end, and within the space of about an hour it died, with all the symptoms of poisoning by strychnia. It may be remembered that Dr Marshall Hall suggested a physiological test for the detection of strychnia; and although Mr Lawrence expressed his satisfaction at the result of the colour tests, he suggested the advisability of trying the strychnia, which I had extracted in a pure state, on a frog; a small quantity being administered, well-marked tetanic symptoms were produced."

The 'Dublin Medical Press' contains an article on the *Chemistry of Pepsine*, by Mr Harry Napier Draper, from which we make some extracts:

"*Composition of the Gastric Juice.*—The best analyses of the fluid which is secreted by the gastric follicles show that it does not contain more than 1·72 per cent. of solid matter, and that while some small portion of this consists of alkaline and earthy chlorides and phosphates, by far the greater part is a peculiar organic body to which the name of *pepsine* has been given. Besides these, the gastric juice contains a free acid. It

would seem at first sight no very difficult matter to decide what this acid really is; but although the question has engaged the attention of many chemists, it can scarcely be looked upon as satisfactorily decided. Opinions have fluctuated between the hydrochloric and lactic, and the nature of the difficulty of forming exact conclusions may be thus shortly stated. The secretion contains, as already mentioned, alkaline chlorides; and supposing lactic acid to be also present, the fluid would, if distilled, give hydrochloric acid, for the reason that slight elevations of temperature cause the decomposition of the chlorides by lactic acid. There are, however, two facts which lead very much to belief in the lactic acid theory. The first of these is, that Professor Graham has long since demonstrated by a process not involving the necessity for distillation that this acid is present in the normal condition of the fluid. The other is, that by a change occurring within the stomach itself, lactic acid is known to be produced. This circumstance I shall again have occasion to advert to.

"*Action of the Gastric Juice.*—It was at one time supposed that the gastric secretion possessed the power of acting upon all the constitutents of the food—that is to say, of acting equally on the nitrogenous, the starchy, and the oleaginous portions. This idea, however, has, since the researches of Frerichs and others with reference to the saliva, been abandoned, and it is now a generally-accepted truth that the proper secretion of the digestive cavity dissolves only the azotized matters which are brought into contact with it. The amylaceous constituents of the food are by means of the saliva, with which the process of mastication impregnates them, converted into *glucose*—a substance which, as far as we are aware, requires no further preparation to be assimilated. The fatty matters are at the same time merely finely divided, and form a kind of emulsion with the chyme, undergoing digestion only after admixture with the biliary and pancreatic secretions. For the proper solution of the food in the gastric juice, heat and motion are two essential conditions. If the temperature of the stomach be lowered, digestion is much impaired; but then, on the other hand, if it be elevated above 120°, the function is altogether checked. The action of gastric juice upon nitrogenized matter has often been carefully observed, not only in cases where the secretion has been obtained by fistulous openings into the stomachs of dogs, but, as in the well-known case of St Martin, in the human subject. If a piece of cogulated albumen, for example, be suspended in a phial containing gastric juice, and the phial be placed in water which is kept at a temperature of 100° Fahr., after a short time the surface of the albumen becomes decomposed, and its edges become rounded. By slightly shaking the phial, the pulpy matter which invests the mass is removed and dissolved in the fluid, exposing a fresh surface to its action; and if this be continued for a few hours the whole will be dissolved. Such a solution of albumen is very different in its constitution and properties to the solution obtained by dissolving albumen in a dilute acid; for while the gastric solution readily passes into the circulation, it has been demonstrated by Bernard that the latter is carried off with the urine. Attempts have been made to estimate the probable amount of the gastric fluid which is secreted in the twenty-four hours, from the assumption that a fixed quantity of the secretion is capable of digesting a certain weight of anhydrous fibrine or albumen. Not only must, in my opinion, such a mode of calculation be deemed fallacious, seeing that there is no evidence that the secretion of the dog, which has always been the subject of the experiments, resembles that of man with sufficient accuracy to admit of the deduction from one of facts which should apply to the other; but I find that the statements of different chemists as regards the solvent power itself differ so widely, that we must cease to regard their results as even approximations to general truth. Thus, for instance, according to Lehmann, about twenty parts of the gastric juice of the dog are required for the digestion of one part of albumen. From these data the amount daily secreted by a healthy man must be from sixty to eighty ounces. But if we are to believe Boudalt, who is one of those who have most recently experimented in this direction, 100 grammes of canine gastric juice will dissolve and digest forty grammes of dried fibrine—a widely different, and, I think, quite irreconcilable result.

"*Nature of Pepsine.*—Pepsine, the organic constituent of the gastric juice, was first isolated and examined by Wasmann. He found that if the mucous membrane of a stomach were treated with cold water and the infusion evaporated to dryness, there remained a viscid, brownish mass, having the odour of glue. The properties of a solution of this substance may be thus shortly stated.

"It is precipitated by the addition of alcohol, tannin, or acetate of lead, forming in the latter case a compound of tolerably definite constitution—peptate of lead. It possesses the power of digesting nitrogenised substances if they are subjected to its action under fit conditions of heat and motion.

"If the peptate of lead be decomposed by sulphide of hydrogen, a solution of pure pepsine is obtained.

"This solution, which is neutral, is of itself incapable of effecting digestion; but if a small quantity of an acid, as lactic or hydrochloric, be added, solution proceeds rapidly. The pepsine seems, therefore, to *dispose* the acid to dissolve the substance, somewhat simulating, in fact, the action of a ferment. Indeed, the ferment theory would seem to be borne out by the action of pepsine upon grape sugar, which it converts into lactic acid. Here I must not omit to allude, in passing, to the manner in which the starchy portions of the food are digested. The action of the ptyalin in the saliva first converts the starch into grape sugar, which is capable of being assimilated without digestion, and by the further action of pepsine upon the grape sugar a sufficiency of lactic acid is produced to carry on the digestion of nitrogenised food. The changes which take place may be thus represented:—

One equivalent of starch = C_{12} H_{11} O_{11} becomes
One equivalent of glucose = C_{12} H_{12} O_{11} which is finally changed into
Two equivalents of lactic acid = 2 (C_6 H_6 O_6).

"*Artificial Pepsine.*—The difficulty of conveniently obtaining the gastric juice of animals for medicinal purposes, and the disgust which many patients not unnaturally felt at its use, soon led to its being altogether discarded, and it is only very recently that, under its new form, it has been reintroduced as a remedy. It occurred to M. Boudalt that if he could separate the active constituent from the inert and useless substances associated with it in the gastric juice, he would be able to produce not only a much less disagreeable medicine, but one of greater certainty of action. This he now effects in the following manner:—The stomachs of sheep are inverted and washed under a very gentle stream of cold water, and with a blunt knife the pepsine-secreting follicles are scraped off and beaten in a mortar with a small quantity of distilled water. The liquid filtered from this, being next treated with a solution of acetate of lead, gives a copious white precipitate—peptate of lead—which is collected on a filter, and after being freed by washing from an excess of the lead, salt is diffused through a small quantity of water. The suspended precipitate is next decomposed by a stream of sulphide of hydrogen, sulphide of lead and pepsine being produced. The former is separated by filtration, and the latter remains in solution. Now, if this solution of pepsine were simply to be evaporated to dryness, all due precaution not to exceed a temperature of 100° being observed, the product would be a gummy, very deliquescent mass, prone to decomposition, and altogether unfit for medicinal use. To obviate these inconveniences and give the pepsine a permanent form, M. Boudalt mixes with the solution, when evaporated to the consistence of a thick syrup, starch powder in certain fixed proportions. This constitutes the 'neutral pepsine' recommended by the inventor in cases where dyspepsia is complicated with abnormal acidity of the stomach. But for cases where there is no undue ascidity a pepsine powder is prepared, to which *lactic acid* is added in such proportion as will give the degree of acidity which canine gastric juice is found to possess. There are also combinations of pepsine with morphia, strychnia, and iron; olla podrida, which I cannot but look upon as being not only unchemical, but calculated to lead to false deductions as to the value of pepsine itself.

"Pepsine should be taken between thin slices of bread, not either before or after, but—in imitation of the natural secretion—*at* a meal. As any excess of temperature beyond 120° Fahr. totally destroys its digestive property, hot fluids should never be taken either immediately before or after its exhibition; and as it is decomposed by alcohol, if spirituous liquids be used at all they should be very much diluted."

Mr Draper is sceptical as to the alleged beneficial use of pepsine, in the small doses given, whilst such large quantities are secreted by the stomach under natural conditions. The Author shows that much of the pepsine sold is absolutely inert.

Schiller as a Surgeon.—Schiller commenced the study of Medicine at Stuttgart in 1775, in the Academy erected by the Duke of Wurtemburg for the benefit of officers' sons. For two years he pursued his Medical studies with great zeal, and wrote a Latin treatise on the 'Philosophy of Physiology,' which was never printed. In 1780 he composed his essay on the Connection of the Animal and Spiritual Nature of Man, which was published in the *Monatsschrift* of Berlin in 1821. In the same year he received the appointment of Surgeon to a regiment in the Wurtemberg army, and performed his duties most satisfactorily. Schiller's intimate friend Scharffenstein has transmitted a ludicrous description of the young Surgeon as he appeared on parade in the full glory of regimentals. His body was squeezed into a uniform cut in the Prussian style. On each side of his face were three thick stiff rolls intended to represent curls; a heavy queue was surrounded by a little military hat, which scarcely covered the crown of his head, and his long neck protruded from a tight horse-hair stock. But the most wonderful part of the costume was the leg and foot attire. The feet were forced into gaiters covered with felt, and two cylinders of great size were compressed into narrow stockings. Schiller studied Medicine rather from compulsion than from choice, and finding that it seriously interfered with his literary labours, he determined to abandon it altogether. This course, indeed, seems to have been forced on him by the Duke, who after the publication of the 'Robbers' sent for him and ordered him to confine his writings to Medical subjects. Feeling this to be impossible, Schiller left his regiment, in consequence of which he was banished from Stuttgart, and was compelled to live under an assumed name in the adjacent towns.

Successful Herniotomy four days after Parturition.—M. Kuhn has published, in the 'Gazette Hebdomadaire,' the case of a woman who was confined of her sixth child whilst affected with inguinal hernia of only a few months' existence. On the fourth day after parturition, symptoms of strangulation showed themselves, and M. Kuhn, finding the taxis extremely painful, operated at once, and succeeded in reducing. The woman did perfectly well.

Small-pox and Vaccination Hospital.—A General Court of the Governors of this Institution was held this week at the hospital. Since the foundation of the hospital, in 1746, it has afforded relief to 273,699 patients; during the year 1859, to 1,185; and during the past six months, to 669, being the greatest number admitted for a similar time since its institution, and several were refused admission for want of accommodation. Under these circumstances it was resolved at the last General Court, that in consequence of the frequent return of epidemics of small-pox and of the crowded state of the hospital, steps should be forthwith taken to provide a separate building or wards to receive the more urgent cases, and thus afford additional accommodation to the public and security to the patients. In accordance with this resolution, applications for plans and estimates were made, and eventually a tender accepted from Mr John Perry for building two additional wards to the hospital for the sum of £3,358, and these wards are to be proceeded with at once. 147,734 persons have been vaccinated at the hospital since the year 1799, and 197 during the last six months, and 120 Medical Practitioners have been supplied gratuitously with 600 charges of vaccine lymph since the commencement of the present year. The receipts for the year 1859 were £2,680 15s. 7d., and the expenditure £2,210 11s. 3d., leaving a balance at the banker's of £469 17s. 4d.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B — The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, JULY 18, 1860.

THE NIGHTINGALE FUND.

We suppose it must be admitted that there is a collapse of the design to establish a grand Institution for the Training of Nurses under the superintendence of Florence Nightingale. The best wishes of mankind followed her steps in her pilgrimage to the Crimea; her tenderness and assiduity, her judgment and benevolence, in discharging the duty she had undertaken, won for her the enthusiastic affection of all the men and women of England, whose eyes dimmed with tears as they perused the recital of her self-devotion; and when she returned to the quiet of her home, a general desire was expressed to perpetuate the memory of her heroism by raising a fund, the proceeds of which should be applied to some purpose of public utility in harmony with the character and labours of this courageous and estimable woman. A Committee was appointed, subscriptions were contributed, and a design was formed to establish a large Hospital for the Training of Nurses; but, unfortunately, at a critical period of these arrangements it became known that Miss Nightingale's health had been irreparably injured by the trials to which it had been subjected, and that should she happily survive for any length of time, she would, nevertheless, be unable to undertake the superintendence of a large Institution.

Whether the gentlemen who undertook the responsibility of collecting the funds felt that to found a Hospital for such a purpose without the advantage of Miss Nightingale's directing judgment and large experience would be to entail failure on the scheme, we know not; but we may remark, that if such a notion guided their reflections, it was quite a mistaken one, and has itself led to the failure of one of the most benevolent and useful designs that have been conceived in recent times. The personal attention of that lady to all the details of management would not have been necessary; and we are sure that there are other ladies, her colleagues in duty in the Crimea, who would gladly have embraced the opportunity of working out the project. It is idle to suppose that the Hospital could not have succeeded without the hourly supervision of the lady whose name it would bear—a name that would have proclaimed the benevolent intention it embodied, and rallied round it a host of generous and active friends.

The fault has been in relying too much upon a *name*, and not venturing enough for a *cause*; a want of conviction, though, perhaps, not of heart, that is the certain forerunner of defeat in all undertakings requiring long-continued energy and determination to ensure their success. Some of those gentlemen, we fear, had not the leisure to devote to the work; and others who had, waited upon those who had not, until the glow of eagerness cooled down, and the project crumbled under the mouldering influences of lassitude, disappointment, and delay.

It is certain that the announcement of the illness of Miss Nightingale damped the spirit of those who were promoting the design, and the subscriptions ceased to be collected; thus the idea of establishing a new Hospital especially devoted to the Training of Nurses gradually disappeared, and the proposal to work out the design upon old foundations took its place. This abandonment of the original plan is deeply to be regretted: it is equivalent to an utter defeat of the design of commemorating in an honourable manner, and for the satisfaction of the grateful impulses of the present generation, the noble woman whose name will be the glory of her sex as long as English history shall be written.

It being determined that there should not be a new Hospital, a struggle commenced among the friends of the several existing Institutions as to which should have the benefit of the funds that had been collected. At one time it was projected, under the partial influence of the Horse Guards, to connect the Training Institution with one of the Military Hospitals; but, for very obvious reasons, this notion fell to the ground. After much delay, St Thomas's Hospital has been fixed upon; and that Institution undertakes to instruct fifteen probationers, and to find them board and lodging, receiving only in return a reimbursement of the expenses incurred by the arrangement. St Thomas's is one of those shady places where the idea of a Training Institution will be most appropriately hidden from public view. The design, ashamed of itself, and mortified with the neglect it has received, seems to have fled to the cool retreats of this subterranean Institution to pine away in secret sorrow, and prepare itself for a premature tomb. The funds, perhaps, will suffice to maintain the semblance of the idea originally propounded; but in reality the nurses will be incorporated with the regular staff, and the money will go as a matter of account into a trust fund, but be applied to the general benefit of the Hospital. The idea of a Training Institution will utterly evaporate, and there is no place where it could do so with less probability of exciting the notice or the commiseration of the public than in the quiet wards of St Thomas's.

So far as the forms of an institution can give reality to it, not even these will be preserved under the present arrangements. There will not be a staff apart from the present resident Medical Officer, Matron, and Sisters, to direct the nurses, and the only appearance of separateness will be the occasional visits of the Committee and a Lady Visitor. We do not understand even that there will be an addition of new Governors to represent the Fund at the Board, and to keep a watchful eye over its appropriation. In short, the Training Institution will be practically incorporated with the Hospital, and so will lose all its distinctive characteristics. We do not say that any other engagements could be made consistently with the good administration of the Hospital, and we do not charge the Governors with accomplishing a job for their own advantage or honour, as has been implied; but we do say that the Committee have not done their duty by the Fund, and have let a grand opportunity slip away of founding an Institution that would have been productive of incalculable blessings to suffering humanity.

SUMMARY OF THE WEEK.

THE COLLEGE OF PHYSICIANS *v.* THE SOCIETY OF APOTHECARIES.

The proposal of the College of Physicians to create a new order of Licentiates in Medicine practising Pharmacy, has excited the jealousy of the Society of Apothecaries, who foresee the utter annihilation of their educational authority should such a proposition be carried out. They have therefore resolved to do their utmost to prevent its realisation. A case has been prepared by them and submitted to Counsel; and the opinion given is, that the College of Physicians have no power to carry out their intention. The value of the opinion, of course, depends upon the accuracy of the statements in the case; and experience informs us that there is never any difficulty in framing a new case out of the same elements, and in getting a conclave of Counsel to upset the opinion already pronounced. The College of Physicians seem to be disposed to try this chance. They, too, are preparing a case for submission to Counsel, and no doubt they will obtain a decision favourable to their wishes, or, at least, sufficiently colourable that they may be tempted to test their right in a Court of Law. It is probable, however, that should the College persevere, the Society of Apothecaries will be the body who will first move the Courts. How often must we deplore the anarchical state of our Profession, and the wretched Corporate rivalries that spring out of such a condition! It would appear that the great Profession of Physic was instituted for

the exclusive advantage of the Corporations, and that the Members were only of consequence as they enriched one body or another, or battled for the maintenance of sectional rights. The conventional distinctions granted by these Institutions enlist the entire body of the Profession in the contest, and hence we have the misfortune to see Graduates arranged against Physicians, Apothecaries against Doctors, Members against Fellows, the public looking on meanwhile, and pitying the men who can indulge in such fierce warfare for such unintelligible objects. So far as this present squabble is concerned, our opinion is favourable to the principle enunciated by the College of Physicians. We desire to see the old Society closed as an educational institution, and limited to its ordinary trading functions. The knell of Apothecaryism is sounded. At the same time, we shall not encourage the College of Physicians in an attempt to create a hybrid class—Physicians by association, but not in name; and unless they offer more favourable conditions to the General Practitioners, shall counsel the course of abstention from the struggle. The General Practitioners do not desire to be tacked on as an inglorious appendage to the skirts of the College of Physicians. The bulk of the General Practitioners are quite as good Physicians as the bulk of the Physicians themselves. We observe that the 'Lancet' falls back this week upon the "One Faculty" scheme as a mode of extrication from the difficulties by which we are beset. The 'Lancet' has many times given worse advice. We like to see this journal recur occasionally to its old principles; for it gratifies us to find that we are not wholly alone in the broad views we wish to take of Medical legislation.

THE TITLE CLAUSES OF THE MEDICAL BILL.

Another case has lately been tried, at Bristol, which has ended in a break-down of the Medical Act. A man of the name of Jacques, practising under the *alias* Blake and Co., Physicians and Consulting Surgeons, calling himself "Doctor," and having the title "Surgeon" over his door, was summoned before the Justices to answer the charge of infringing the Medical Act. Evidence in support of the charge having been heard, the magistrate decided that "a man might use every title named in the Act, if he did not use it for the purpose of implying that he was recognised as a practitioner under the Act." We have said that this was a break-down of the Act: this expression was hardly correct; it was a break-down of the case of those who wished to put the Act to a greater strain than it would bear. It is very vexatious, however, to find that the Act is inefficient against unqualified pretenders.

DR MACLOUGHLIN.

Last week Mr Brady brought the case of Dr Macloughlin under the notice of the House of Commons. It appeared that Dr Macloughlin having felt aggrieved at some alleged injustice done him in promoting juniors over his head, went on half-pay; he was afterwards called to active service, and declined to go; he was then cashiered. Mr Brady made the attempt to reinstate him. It was, however, generally felt by the House that the insubordination o which Dr Macloughlin had been guilty did not justify a lenient course towards him, and they allowed the decision of the Board to remain.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

Two brothers, William and John Hunter, having obtained the highest honours and rewards, native and foreign, in the same field and in the same profession, is a circumstance which demands no indifferent or hasty retrospect. At the same time it must be recorded that another brother, the eldest of the family of the Hunters, who had been trained to the law as Writer to the Signet at Edinburgh, became so captivated with the books he found, and the pursuits of anatomy in the dissecting-room, on a visit he made in 1742 to William Hunter in London, that he also devoted himself to the study of physiology and anatomy. His ardour in the prosecution of these studies was such, that impaired health resulted from unremitting application to anatomy in the dissecting-room, and this brother died, from spitting of blood, when he was twenty-eight years of age, at Kilbride, in Scotland. He is described as having been of uncommonly pleasing address and quick parts, and Dr William said, "that if he had lived to practise physic in London, nothing could have prevented his rising to the top of his Profession." Had he lived, the circumstance of three brothers being rivals in the same career of distinction and honour would have occurred, and perhaps the more amiable temperament and seniority of the latter of the three might have moderated the rivalship and mitigated the spirit of emulation, which on many occasions broke out into envy and jealousy between William and John Hunter. This attachment to the Medical Profession was hereditary in the family, and the fame of the Hunters survived, and was represented by the career of a not less distinguished physician and eminent anatomist, their nephew, Dr Matthew Baillie, and the distinguished authoress Miss Joanna Baillie was his sister.

John and William Hunter explored the paths of physiology and natural science, and carried their inquiries where not even a track existed to guide their ambitious aims, entirely at their own cost, with unexampled perseverance and labour. John, more especially, by connecting the art of surgery with natural history and natural science, elevated its teaching to the level of philosophy. He found a large province unexplored, and, with the fresh and vigorous perceptions of an original mind, he eagerly investigated the relations of functional actions with matter and organization, thus erecting a framework upon which to establish new doctrines and general principles. The circumstances attending the early life of John Hunter were widely different from those of William: John was the youngest child of a large family; at his birth his father being seventy years of age.

John, the son of John and Agnes Hunter, was born at Kilbride, in the county of Lanark, on February 13th, 1728. His grandfather on the mother's side, a highly respectable citizen of Glasgow, of the name of Paul, occupied the position of Treasurer of the City of Glasgow. Disputes have arisen about the correct date of his birth, his biographer and relative Sir Everard Home having given July 14th, 1728, which date is observed by the College of Surgeons of London in their celebration of John Hunter's anniversary. The testimony given of his birth by his friend and pupil Dr Adams (who has also published a biography of John Hunter), obtained through the Rev. James French, minister of Kilbride, from the parish register, conclusively decides the first date to be correct. John Hunter's early life was left to the exclusive care of a mother who became a widow when he was ten years old. The doting affection of a mother to an only child, remaining to claim her solicitude, permitted indulgence in every possible way. Village pastimes and recreations, in the absence of the restraint which tuition requires, induced a taste for dissipation incident to country amusements and want of regular occupation. When at the age of seventeen, being placed at a grammar-school, he was totally unfit, from the desultory life he had led, for the application necessary to obtain a classical education or a knowledge of languages; and throughout life John Hunter was deplorably ignorant of the first elements of tuition, and his orthography would certainly not have sustained the competitive examinations of our day. The restraint this discipline imposed became intolerable, and the fascination of country amusements confirmed the distaste he felt at the confinement required by study, in the absence of any emulation from the example of brothers or sisters. Both his sisters were married; and he incurred a fate which marked the career of some men, who, notwithstanding, arrived at eminence. Men of enterprise, when once awoke to the necessity of diligence, by assiduous application, will quickly arrive at an enviable and honourable position. Amongst those who, in defiance of early neglect, have left lasting testimonies to their genius and merits, we may name the philanthropist Howard, the circumnavigator Captain Cook, Dean Swift, and, in our own day, Horne Tooke and Lord Byron. These examples, however, form exceptions to a rule that application and study are essential to attain fame and fortune, the absence of which nothing will compensate.

The youngest sister of John Hunter had, contrary to the wishes of her friends, made an unfortunate marriage with a Mr Buchanan, of London, who had commenced business at Glasgow as a cabinet-maker. Of specious address and fascinating manners, fond of music and a good singer, Buchanan gave himself to society and dissipation, and soon became embarrassed in his affairs. For his sister John Hunter entertained great affection, and, in his seventeenth year, he paid her a visit, to condole with her misfortunes, and, if possible, to help in preventing the ruin in which Buchanan was becoming involved. This incident gives origin to the statement, "a wheelwright or carpenter he (John Hunter) certainly was." (*a*) If true, this can in no degree diminish, but rather enhances, the high merit to which he in after life attained. It is very possible the mechanical skill obtained as a cabinet-maker may explain the wonderful delicacy and proficiency he acquired in making anatomical preparations. How many of our cleverest men of science might envy an accomplishment which could only be arrived at through such a noviciate! If John Hunter served an apprenticeship to his brother-in-law, who was a carpenter and cabinet-maker—as one of his biographers, Jesse Foot, states—when that business failed he was necessarily thrown out of employment. A rumour prevailed that he was compelled to leave Glasgow, on account of a fray he had with some soldiers of the Pretender's army in defending himself from an attempt to steal his shoe-buckles. If so, the youth manifested the same spirit of adventure and resentment which frequently characterised the man, a paroxysm of the last having caused his death. Nevertheless, his incredible labour, assiduity, and perseverance in dissection might, not unlikely, date from the practice of the art of cabinet-making. "In originality of genius and powers of investigation John appears to have surpassed his brother William — industry and perseverance equally belonged to both." (*b*) Dr Adams says, speaking of William, "that, with the mildest manners, and, I firmly believe, with the most upright, and for the most part the kindest intentions, he seems

(*a*) 'Life of J. Hunter,' by Jesse Foot, p. 10.
(*b*) 'Oxford Encyc.'

unfortunately to have considered warm controversy, if not necessary, at least venial, for those who write to become considerable in anatomy or in other branches of natural knowledge." (c) In the state of difficulty John Hunter found his sister's husband, it is probable that he occasionally assisted, by working, to relieve their embarrassment; and in country towns a carpenter and cabinet-maker are usually combined. Buchanan becoming more and more involved, ultimate insolvency induced him to relinquish cabinet-making, and to become a teacher of music and clerk to an Episcopalian church.

(To be continued.)

REVIEWS.

A pile of pamphlets and small books has long been petitioning for a notice, and the cry shall now be responded to. The first pamphlet that meets our eye is the *Annual Report of the Belfast District Hospital*, a very succinct and able statement of the statistics of that well-managed institution. We observe a few significant figures in the tables: thus, during the year ending March 31, 1860, no fewer than sixteen persons, of whom fourteen were females, were admitted into the Asylum from insanity caused by "religious excitement." To what extent is this attributable to the "revivals" in the North of Ireland? We do not find any explanation of these remarkable figures in the body of the Report—an omission that is very unsatisfactory. Dr Stewart, the Resident Medical Officer, has introduced a brass band for the amusement of the patients with much advantage, and he has also afforded them the relaxation of walks in the fields—a liberty which they seem to have enjoyed. We congratulate Dr Stewart on the success of his enlightened administration.—Mr Gay's anniversary Oration before the Medical Society of London on the *Aspects of Medical Science* is a very creditable production. The style is elegant and flowing, and the Author treats his subject in an elaborate and critical manner. —Another Oration, read before the Hunterian Society by Dr Stephen Ward, entitled *Rational Medicine*, and treating of its position and prospects, is philosophical in tone and deserves our commendation.—Mr Robert Dunn has reprinted a paper read before the Obstetrical Society on the *Statistics of Midwifery*, collected from private practice. These statistics afford a fair sample of cases as they occur, and are better qualified to form a foundation for rules of practice than the statistics of cases observed in hospitals alone. Mr Robert Dunn has had extensive experience, the number of cases he has recorded amounting to 4,049 — the total maternal mortality 27, as follows:

"2 deaths from *flooding*, 1 *before* delivery was effected, and 1 four hours *after* it, from internal hæmorrhage; 3 deaths from *exhaustion*, soon after child-birth. In 2 of these there was excessive hæmorrhage *before* delivery, and in the other none, either before or after, but an advanced stage of phthisis: 2 deaths after craniotomy, 1 in whom there existed a tumour at the neck of the womb—the patient sank from exhaustion undelivered, after the head was perforated; the other from sloughing of the bladder and vagina: 1 death from inflammation of the uterus; 3 deaths from puerperal peritonitis; 5 deaths from puerperal fever; 2 deaths from phlegmasia dolens, 3 from puerperal mania. Total 21.— 2 deaths from disease of the liver; 1 death from disease of the lungs; 1 death from disease of the heart; 1 death from disease of the brain; 1 death from scarlatina. Total 6.

"In regard to plurality of children, there were 2 cases of triplets, in one of which each of the children had a separate placenta, but none of them lived. Forty-five cases of twins, in the great majority of which both the children were in connection with one placenta. I met with 3 cases of *monstrosity*."

(c) 'Adams' Memoirs,' p. 133.

Again he says:

"*Of still-born children*, in the 4,049 cases, after subtracting the 228 premature births, there were in all, from whatever cause, 170; including in this number, putrid cases, funis, and preternatural presentations, forceps, and craniotomy cases, as well as deaths from pressure in tedious and difficult labours. Of the last there were 30 cases. Of preternatural presentations I had upwards of 60 instances. Out of 11 cases, in which there was a prolapsus of the funis, 8 were born dead; and of these still-born children, in 3 instances a coil of the cord came down with the head, in 2 with the head and arm, in 1 with the foot, and in 2 with the shoulder. Out of 25 breech presentations, 9 were still-born, and of these 5 of the children were putrid. In breech presentations I have, more than once, lately had an opportunity of testing the value of the *ready method* of Dr Marshall Hall, in cases where animation has been suspended, and in the happy results which followed I can bear a willing testimony to its practical importance and value. I had 3 face presentations, and one of the children was still-born; 11 cases of face to pubes; 2 of head and arm, both dead; 3 of shoulder, and 2 still-born; 3 of hand, and 3 of footling cases.

"I met with one case of natural labour which puzzled me, and I sent for my friend, Dr Waller. The patient was in strong labour when I arrived, and I imagined at first that the child's head was actually entering the world. It did not, however, and upon careful examination, and in attempting to pass my hand around it, I found it was not the head. It turned out to be an *unruptured hymen*, in which Dr Waller detected a small opening, not larger than to admit a crow-quill. A free crucial incision was made, and through this, after the next pain, the os uteri was readily felt, considerably dilated. The pains followed up, and the patient had a safe delivery and a good recovery. I attended her in two or three subsequent labours, which presented nothing abnormal. I need scarcely say, that her husband was well pleased with the results of her first accouchement. I found that he had been aware of an existing impediment to sexual intercourse.

"I must confess that I have had but slender experience in the use of the forceps, not having applied them myself more than twenty times during the twenty years I am now reviewing, and never on any occasion, *save once*, without the presence of a medical friend or my assistant."

What question is there that demands the serious consideration of obstetricians more than the use of the forceps? Dr Pettigrew told the same Society that he used them in one case in seven; and here is Dr Dunn, with, we apprehend, a much larger experience, stating that he scarcely ever resorts to them! Further on Mr Dunn says:

"I had 10 cases of craniotomy: 4, in consequence of distortion of the bones of the pelvis; 5, of impaction of the head; and 1, owing to a tumour at the neck of the womb. Two proved fatal to the mothers; one from sloughing of the bladder. One poor woman had been in labour for two days, and in the care of a midwife, before I was called to her, and was then in a state of great prostration. She died on the third day after delivery. The other was a case of some obscurity. The patient had been subject to gushes of bloody water from the fifth or sixth month after gestation, and to frequent diarrhœa. Her health gave way, though she went her full period. I could not make out the presentation—I thought it was *placental*, and so did other medical friends, as a spongy substance completely filled up the mouth of the womb. Dr Blundell, however, after a careful examination, declared this to be a tumour, and said that he could, with his finger, reach the head of the child, which was still covered by the membranes. These were ruptured, and the head, after some difficulty, opened. But then humanity said, *desist*, for the poor creature was completely exhausted and sinking fast. Cordials and stimulants were useless. She died undelivered. At the autopsy there was found, within the cavity of the womb and at its neck, an *encephaloid tumour*, as Dr Blundell had foretold.

"In two instances craniotomy was had recourse to, for a second time, on the same woman, and in subsequent pregnancies premature labour was induced. In six other cases I brought on labour at the seventh month, by rupturing the membranes; but in no instance, save one, did the child survive. Of placenta prævia I had three cases, and since 1850, and subsequent to the promulgation of Dr Simpson's views and mode of procedure, I have had three more. In about thirty instances I found the placenta adherent, and requiring the introduction of the hand; in four I met with the hour-glass contraction."

Some excellent practical observations follow on hæmorrhage.—The same Author has recently published a pamphlet on the *Tegumentary Differences which exist among the Races of Man*, which is an attempt to prove that these differences are produced by accident, climate, &c. &c. Mr Dunn's reasoning does not satisfy us, though some of the facts, which are well known, are strong and plausible. —A pamphlet styled *A Few Remarks on the False Assumption of Medical Titles* may simply be consigned to the tomb of the Capulets, where it will do no harm.—Mr Edwin Lee favours us with *Additional Notes* on the State of the Medical Profession. The Author, as a reformer and an iconoclast, understands the wants of the Profession, and writes with vigour.— *Spinal Curvatures and Deformities of the Chest and Limbs* is a work by a lady, Mrs Godfrey. This is said to be a third edition, though it is the first that has reached our hands. The Author's mode of treatment consists in what her "patients call *the power of the peculiar touch*." This, of course, it is impossible for us to comprehend or explain, not having come under her peculiar manipulations. There is very much said about *my system* in the book, but no explanation of it is given. We gather, however, that Mrs Godfrey objects to mechanical aids, and is favourable to Ling's movement cure. She points out the evils arising from errors of management in relation to posture, exercise, gymnastics, &c. &c., the meaning of which is that all these things are good if directed by Mrs Godfrey's "peculiar touch." —*The Wife's Domain*, by Philothalos, contains much useful advice conveyed in a sober and reasonable style.—Mr Dale contributes to our medico-political literature a pamphlet on the *Present State of the Medical Profession*, which embraces much practical information about hospital administration and the scholastic curricula.—Dr Cockle has supplied a want very gracefully in this, the first part of a series of Lectures upon the historic literature of the *Pathology of the Heart and Great Vessels*. It will requite perusal; but the form in which it is produced is too unassuming—a fault we do not often condemn.—In a small pamphlet, Mr Lee has given the Profession his view on the *Radical Cure of Varicocele* by subcutaneous incision. His practice may not be known to all our readers. We may state that it consists in placing a needle under the vessels, both below and above the part to be divided, and then winding ligatures, in the form of figure 8, round the ends of the needles and over the vein. He says:

"When this is accomplished, there is no necessity to wait until the vein is obstructed by coagulum before performing the operation of subcutaneous section; and accordingly, at the suggestion of my colleague, Mr Bowman, I have now on many occasions divided the vein immediately after the introduction of the needles. The small quantity of blood situated between the needles at the time of the operation is allowed to escape, the sides of the vein fall together, and the whole heals by first intention.—at least, it has done so in all the cases upon which I have operated. But even should suppuration occur at the seat of the wound, the vein being closed above and below, no morbid secretion can find its way into the circulation."

The following observations should be borne in mind:

"It is sometimes difficult to be sure that the needles introduced pass fairly under the vein; but this object may, in the great majority of cases, be certainly obtained by a little manœuvre. The

vein is first pressed out of its bed with the finger, and the needle is then introduced, so that its point may fall into the bed of the displaced vein. The needle being then left at rest, the vein is allowed to regain its natural position, and in so doing it rolls over the point of the needle. The vein is then pressed with the finger in the opposite direction towards the head of the needle, and its point may be brought out without danger of injuring the vessel.

"When a needle is passed in this way fairly behind a vein, and left there for two or three days only, it is almost impossible that it should excite any mischief in the interior of the vessel, while the pressure it exerts effectually prevents either hæmorrhage or absorption.

"In operating upon large veins, it is a point of primary importance that the needles should always pass fairly behind them; for if they transfix the vessels, an interval may be left between the needle and the side of the vein farthest removed from the surface. Independently of the chance of exciting inflammation by puncturing the coats of the vessel, the channel may then not be completely closed, and a passage to the general circulation may be left for any morbid product that may be present.

"The case is, however, different with regard to small veins: when a needle pierces one of these, its small cavity must necessarily be very nearly, if not quite, obliterated. The same care, therefore, is not necessary in operating upon veins of a small size. Clusters of varicose veins in the legs may, for instance, be pierced by a needle, and tied with impunity. If an '8' ligature is placed round the ends of the needle, the small veins which may happen to be punctured are subsequently as completely closed as if the needle had been made to pass under them.

"After the introduction of this operation for varicose veins in the lower extremities, it was not long before an opportunity presented itself of treating the varicose veins of the spermatic chord in the same manner. It was evident, in this case, that it would be impossible to avoid puncturing the veins occasionallly when the needles were introduced; but, from the comparatively small size of these, no danger was apprehended; nor has any evil, as far as I am aware, resulted."

The Acclimatization of European Troops for Service in India, by Dr James Bird, deals with a subject of considerable interest at the present time. The suggestions of the Author, who has had great practical experience, deserve attention.—Dr Edwards Crisp's work on the benefits likely to accrue from the formation of an *Agricultural Museum* in London is a little out of our line, though we fully recognise the advantages he describes. His second pamphlet, on the *Cause of Death of many of the Animals at the Zoological Gardens*, is more to the purpose of a Medical Journal. The Author observes:

"I may express my *belief that the nature of the diseases of man will not be thoroughly understood, nor appropriately treated, until the deviations from normal structure are fully investigated in plants and in the lowest grade of animals:* a doctrine, I believe, not promulgated before, and one that will be laughed at by many; but I have the greatest confidence that this mode of throwing light on the dark and uncertain nature of the art of medicine will hereafter be adopted.

"For the purpose of pointing out what I believe to be the importance of this matter, I trust I may be pardoned for quoting a short extract from my work on the Spleen, written in 1852:—'Nearly all the great discoveries in physiology have been made by experiments upon living animals, in a state of health; but why should not their diseased conditions be turned to account? Why may not brute pathology hereafter clear up some of the doubts and difficulties of our art? The examination of one of the lower animals that has been kept in confinement is attended with these great advantages:—the exact nature of the food, and the deviations from the natural state of the animal, can be readily ascertained; and if the animal is small (a bird *e.g.*), the morbid parts are revealed at once, and the chain of causes is more apparent than in larger quadrupeds, the investigator always taking into account the peculiarities of structure.'"

We trust that Dr Crisp will follow up this subject. It is a new and very interesting field of research.—*On Diabetes and its Successful Treatment*, records the experience of Mr Camplin in the use of bran bread. Mr Camplin himself has been a sufferer from diabetes, and in relating his case he remarks:

"Having before this seen Dr Prout occasionally, and now telling him of my dilemma, he suggested a kind of bran cake, which was immediately prepared according to his directions: it was by no means a pleasant composition, but that was not the worst, for the bran acted powerfully on the bowels, and it could not be continued in that form. We have all heard that 'necessity is the mother of invention,' and I immediately set a mill-maker to work to make me a mill which should grind the bran into a very fine powder; this means, and careful sifting, overcame the difficulty, and enabled me to succeed in the preparation of a kind of cake which was continued for some years, and with the best effects.

"I had before this been more rigid in my diet than directed by the doctor, who, to use his own expression, 'tolerated things which he did not advise.' My protracted sufferings, however, now determined me to put away everything saccharine or amylaceous to the utmost possible extent, and I therefore gave up wine, at the same time that the bran cake enabled me to discard entirely the use of bread. I now soon became decidely convalescent, and have never had my diabetic symptoms return with violence."

As the dietectic part of the treatment of this affection is of great importance, we have pleasure in extracting the following sentences, which convey Mr Camplin's personal experience:

"To return to the early history of my case.

"Fat meat and eggs were more especially directed for me, and were taken without any immediate ill effects; but I am of opinion that they produce great biliary derangement, more especially the eggs, the free use of which has been laid aside long since.

"Fish is a most important article of diet for the diabetic, but does not require particular notice, as its use only requires the ordinary cautions for those in moderate health.

"I have never found it necessary to disallow the use of milk; the sugar contained in it certainly does not pass into glucose readily, or under ordinary circumstances; and this induces me to notice, that, as to farinaceous substances, their disposition to pass into sugar is not to be estimated simply by their proportions of gluten and starch, and it does not seem to me that anything but experiment will determine the degree in which they do this. Some kinds of bread injure more than others; and in my own person brown bread has often produced greater sweetness in the saliva than that made of fine flour; and it is my opinion that unfermented flour in the various forms in which we use it is less liable to pass into sugar than bread. I have not, however, had opportunity to test this on a sufficiently large scale to be certain of the fact.

"With regard to vegetables, I have almost confined myself to the cruciferæ, as they can be obtained in London during the greater part of the year; the young cabbage is, perhaps, at once the cheapest and best for ordinary use. Cauliflowers, broccoli, Brussels sprouts, &c., give considerable variety. Sea-kale is excellent, but rather too expensive: the late Dr Pereira recommended sour krout to me; but having fresh vegetables at hand, I have never tried it. Since my recovery I have taken French and scarlet beans, without injury; but should consider the cabbage tribe highly preferable for the actually diabetic. Spinach is generally considered allowable, and indeed recommended; and those who reside in the country might add to the list other plants of the same natural order, such as the Chenopodium bonus Henricus, and the younger leaves of the common beet, both of which I have tasted, and found them very agreeable. My friend, Mr Ward, in conversation with him on the subject, suggested that the leaves of the Beta cicla and maritima may be used as pot-herbs; and perhaps the list might be still further enlarged.

"As to tea or coffee, I have no hesitation in giving the opinion that, in a majority of cases, tea is to be preferred. Milk may be taken with it freely; cream sparingly.

"As a beverage at meals, water or toast-water may be used, and, instead of wine or malt liquor, a small quantity of brandy and water, not above a table-spoonful of the former. Wine is better excluded, except claret, which is too expensive for common use. There are several other wines which may be allowable as being free from sugar, but of them I have no experience. The pale French brandy is, no doubt, the best; but I have tried the English eau-de-vie made in imitation of it, and found it to answer very well; and Dr Bence Jones informs me that he has sometimes directed rum, which, being without sugar, is, *quoad hoc*, as eligible as brandy. Sponging with tepid water, followed by friction, has been so beneficial, in more than one case in which I have been consulted, as to call forth the highest encomiums. For myself, I have only practised sponging with cold salt and water in the summer, and an occasional warm bath in the winter: these I have used with great advantage.

"Warm clothing—leather waistcoat, and gutta percha soles to the boots, in winter, are very important. It would be superfluous to descant on the advantages of change of air and occupation; but I may mention that, when restricted to the use of the bran cake, at home, if I left town for a time, and took the prepared bran with me, I seldom used it beyond two or three days, and never felt the worse for taking the liberty of substituting bread under the influence of change of air and scene. When I returned home I continued the bread, until warned by a partial recurrence of symptoms to have recourse to my bran cake. This took place several times before I was able altogether to discontinue its use."

This is a very useful little *brochure*.

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, JUNE 23RD, 1860.

Royal College of Physicians, London.

Mr GREEN took the Chair, at one o'clock p.m.

Present—Mr Nussey, Dr Acland, Dr Bond, Dr Embleton, Dr Storrar, Dr Alexander Wood, Dr Andrew Wood, Mr Watt, Mr Syme, Dr A. Thomson, Dr A. Smith, Dr Leet, Dr Apjohn, Dr Corrigan, Sir James Clark, Sir Charles Hastings, Mr Lawrence, Mr Teale, Dr Christison, and Dr Stokes. —Dr Francis Hawkins, Registrar.

The Minutes of the last meeting were read and confirmed.

1. Moved by Dr Christison, seconded by Mr Nussey—"That the letter from Sir Benjamin Collins Brodie, which announces his wish to resign his office as President of the Council, is received with sincere regret; that the Council tender their best thanks to him for the various and eminent services which he has rendered to the Medical Council; and that they cannot refrain from adding that he will carry with him the esteem and respect of every Member of the Council, into all the other departments of his honourable career."

The motion was put and carried by acclamation.

2. Moved by Dr Corrigan, seconded by Sir Charles Hastings, and agreed to—"That a copy of the foregoing Resolution be forwarded to Sir B. C. Brodie."

3. Moved by Dr Andrew Wood, seconded by Mr Teale, and agreed to—"That the Resolution of the General Council of August 6th, 1859, No. 5,—'That the General Medical Council have observed that Amendments of the Medical Act have been introduced, at the instance of Bodies represented in the Medical Council, into Bills brought into Parliament without previous communication with the General Medical Council; and that the Council consider it desirable that, in future, such Amendments should be first communicated to the President of the Council'—be amended, by adding 'to be by him communicated to the Members of the Council.'"

Dr Alexander Wood brought up the second Report of the Committee on Special Claims for Registration.

REPORT:

"The Committee had under their consideration the following cases:

"Frederick Theophilus Webster.—This gentleman claims to be registered under Clause XLVI of the Medical Act as 'a Surgeon in the service of a Charitable Institution;' he being Surgeon to several Benefit Societies. Mr Webster was appointed by the Guardians to the office of Medical Officer in the St Alban's Union, there being no other candidate, but the appointment was not confirmed by the Poor-Law Board. Mr Webster supports his application by testimonials, which fully prove both character and ability, and a letter has been received from Messrs Farrer, Ouvry, and Farrer, the Solicitors to the Council, in reference to it. Mr Webster's claim is opposed by Mr Hutchinson, who resides close by him, and who formerly supported the claim of a gentleman no better qualified. On the whole, the Committee are disposed to recommend that Mr Webster be registered."

"Antoine Rischanck claims registration on a Surgical Licence from the Medical Faculty of Vienna. There was produced to the Committee a letter from the Dean of the College of Doctors of the Medical Faculty of Vienna, stating that Mr Rischanck 'absolved the Medical and Chirurgical course of Study, formed for the purpose of educating Country Surgeons; he studied for three years, and passed his examination on the 28th January, 1838, as Patron of Surgery and Midwifery (Surgeon and Accoucheur); he took his oath, and possesses a Diploma of the same date.'"—(Recommended for registration.)

"Albert Günther, M.A., Dr Phil., Tubingen. —Diploma in Medicine and Surgery from the Medical Council at Stuttgart."—(Recommended for registration.)

"Theodore Günther, Emil Becher, and Charles Milner obtained their degrees of Doctors of Medicine at Tubingen, after regular examination, and are recommended for registration.

"Jonathan Sibley obtained his degree as M.D. from the University of New York, after examination."—(Recommended for registration.)

"Frederic Hancorne Prytherch and James Godfrey obtained their degrees, after regular examination, at Heidelberg."—(Recommended for registration.)

"Michael Lambton Este, in addition to his titles already registered, wishes to be registered as M.D. of Erfurt—Diploma produced."—(Recommended to be registered.)

"Daniel B. Bascombe claims Registration, as M.D. of the University of Pennsylvania. The Dean of the Medical Faculty has failed to satisfy the Council that his degree was obtained after regular examination; it is therefore recommended that the consideration of this case be delayed, but that power be given to the Branch Council for England to register Dr Bascombe, should they be satisfied meanwhile that he was duly examined."

The following qualifications are recommended to be rejected:—"William Hitchman, M.D., of the Protestant University of Bavaria—without examination; Theodore Bloomenthal, M.D. Wurzburg, obtained after the passing of the Medical Act; William Leger Erson, claims to be registered as a Licentiate of Midwifery of the Combe Lying-in Hospital.

"ALEX. WOOD, Chairman."

---

4. Moved, separately in each case, by Dr Alexander Wood, seconded by Sir Charles Hastings, and agreed to—"That Theophilus Webster, Antoine Rischanck, Albert Günther, Theodore Günther, Emil Becher, Charles Milner, Jonathan C. Sibley, Frederic Hancorne Prytherch, James Godfrey, and Michael Lambton Este be Registered."

5. Moved by Dr Alexander Wood, seconded by Sir Charles Hastings, and agreed to—"That the recommendation of the Committee respecting Daniel B. Bascombe be adopted."

6. Moved, separately in each case, by Dr Alexander Wood, seconded by Sir Charles Hastings, and agreed to—"That William Hitchman, Theodore Bloomenthal, and William Ledger Erson be not registered."

Dr Smith presented the following Report from the Finance Committee, appointed June 13, 1860:

"The Committee having taken into consideration the matters referred to them, respecting the Financial Affairs of the General Medical Council, report, that the Minutes of the General Council and the Executive Committee, and the Cash Accounts of the General Council, are kept in accordance with the recommendations of the Finance Committee appointed in 1859.

"With the view of bringing all the matters referred to the Committee under the notice of the Council in the most concise manner, they have been arranged as follows:—

1st. "Matters referred to the General Council by the Executive Committee and the Branch Council for England (see Resolution 7).

2nd. "Resolutions suggested by the Committee (see Resolutions 8 and 9).

3rd. "Recommendations of the Committee,—to be referred to the Executive Committee."

---

7. Moved by Dr Alexander Wood, seconded by Mr Watt, and agreed to—"That in striking the Annual Percentage Rate in accordance with Sect. XIII of the Medical Act, the words 'all monies received' be understood to mean, all monies received by the respective Branch Councils, from whatever sources derived."

8. Moved by Dr A. Smith, seconded by Dr Andrew Wood, and agreed to—"That the Scale of Fees adopted on the 3rd of August, 1859, for attendance on the General Council, the Executive Committee, and the Branch Councils, and also for travelling expenses, which was approved of by the Commissioners of Her Majesty's Treasury, be adhered to, until altered by the Council."

9. Moved by Dr Burrows, seconded by Dr Andrew Wood, and agreed to—"That the non-resident Members of the General Medical Council shall be paid Hotel Expenses for every Sunday while in London on the business of the Council."

10. Moved by Mr Lawrence, and seconded by Mr Nussey—"That the Resolution proposed by Mr Syme, No. 3, in No. 21 of the Minutes of the General Council, be rescinded."—Negatived.

Dr Christison presented the following Report on the mode of Conducting the Business of the Council:—

"The Committee appointed on the 20th of June, to extract from the Minutes of Council such regulations as have been passed by the Council for conducting the business of the Council, and to report such alterations and new regulations as may appear to the Committee to be advisable, have to report, that the Minutes contain the following Resolutions passed by the General Council for Conducting Business:—

"1. The General Council shall meet each day at 2 p.m., and shall not sit after 6 p.m. (August 3, 1859, p. 4.)

"2. It is expedient that the proceedings of the Council be recorded in writing, in a book to be kept for that purpose. (August 10, 1859, p. 9.)

"3. That the Minutes of each Meeting of the Council, as well as all Notices of Motions, be printed, and transmitted to each Member of the Council. (November 23, 1858, p. 3.)

"4. That the Minutes of the several Meetings of the Council shall contain simply such Resolutions and Amendments as have been proposed and adopted, or negatived, with the name of the Proposer and Seconder, and without any comment or observation of Members annexed. (November 24, 1858, p. 1.)

"5. That a Programme of the subjects which it is the intention of Members of the Medical Council to bring forward, be forthwith prepared by the Registrar, be printed and distributed by him from day to day, as may be required, and that a Committee be appointed to aid the Registrar. (August 3, 1859, p. 4.)

"6. That any Motion or Motions lying over from the previous day take precedence of new matters, except by special permission of the Council. (August 6, 1859, p. 1.)

"7. That in all cases where a division has taken place, any Member of the Council may require that the names of the majority and minority shall be entered on the Minutes. (August 11, 1859, p. 2.)

"8. The Business Committee shall report as to the form in which New Members shall take their place, both in the Branch Councils and in the General Council. (June 16, 1860, p. 2.)

"9. That whenever a Branch Council shall refer to the General Council the name of any person which it is deemed desirable to remove from the Register, the Registrar of the General Council shall be authorised to obtain the opinion of Counsel on the facts and bearings of the case, before it is submitted to the General Council; and that such opinion of Counsel shall accompany the statement of the case when it is brought before the General Council. (August 10, 1859, p. 9.)

"The Committee have considered whether it is desirable to alter or add to these Regulations. They do not propose that the Council should alter any of the Regulations already passed. They think it undesirable to attempt at present to construct a complete code of Regulations for conducting the business of the Council; that much may be safely left to evident convenience and well-known usage; and that it will be sufficient to provide, by additional Regulations, for those points in the conduct of business which have become the subject of serious difference of opinion among the Members.

"These are two in number: first, the mode of dealing with Motions and Amendments; and second, the reception of Protests.

"(1.) As to the mode of dealing with Motions and Amendments, the Committee find that three usages prevail in various public bodies, in the three divisions of the United Kingdom. One of these has been adopted, and extended into precise Rules, by the London University Convocation. As these Rules have been found by the Convocation to answer well in practice, and appear to the Committee well fitted to bring out the sense of such Meetings as those of the General Medical Council, they are now recommended for adoption, as follows:

"*a.* No Motion or Amendment shall be withdrawn, after being put from the Chair, except by leave of the Meeting.

"*b.* Any number of Amendments may be moved.

"*c.* If there is but one Amendment, the Amendment shall be the first question put to the Vote; and in any case where a Motion and more than one Amendment shall be before a Meeting of the Council, the first question put to the vote shall be 'That the original Motion be amended.'

"*d.* In the case of there being but one Amendment, if such Amendment be lost, or, if in the case of there being several, it be carried that the original Motion be not amended, the original Motion shall then be put to the vote.

"*e.* If it be carried that the original Motion be amended, the Amendments shall be put to the vote in the order in which they shall have been moved.

"*f.* No Discussion and no Amendment shall be allowed after the first question has been put to the vote.

"This mode of procedure differs from the mode recommended from their experience by the Scotch Members of Council, only in so far as it is the practice in the Bodies with which they are connected to put the last Amendment first. The Committee do not consider it material which of the two ways of putting the vote is adopted. But they think either of them better fitted to bring out the true sense of a Meeting of such a body as the Council, than the third which has been brought under the Committee's notice; according to which, no Amendment can be put to the vote at all, or even so much as minuted, unless the previous Amendment, or the Motion itself, be withdrawn.

"(2.) As to Protests, the Committee consider it very undesirable that these should appear on the Minutes, when they can be avoided. But, on mature consideration, they are of opinion that the right of a minority to protest, and to have their Protest entered in the Minutes, is a right which cannot be refused, without risk of substantial injustice to the minority, and eventual damage to this Council in its relations to the public.

"R. CHRISTISON, Chairman."

---

11. Moved by Dr Christison, seconded by Dr A. Smith, and agreed to—"That the Report of the Committee on the mode of conducting the business of the Council be received, and printed in the Minutes."

Letters having been read which had been received from the Devonport Registration Association, relative to the Registration of Edwin Bishop,

12. Moved by Dr Storrar, seconded by Dr Christison, and agreed to—"That the decision of

the Branch Council for England on appeal in this case be not interfered with."

A Letter having been read from Dr Scott, of Boulogne, relative to the Registration of J. M. Cookesley,"

13. Moved by Dr Alexander Wood, seconded by Dr A. Smith, and agreed to—"That Dr Scott's Letter be remitted to the Branch Council for England."

Dr Andrew Wood presented the following Report on the Forms to be observed on the Introduction of New Members of the Medical Council :

"The Business Committee, to whom was committed the duty of preparing a Report as to the forms to be observed when New Members take their place on the Branch Councils, or on the General Council, beg to report that in their opinion it is desirable that the following regulations be followed, viz. :

"1. That it be the duty of the President, on receipt of intimation of the resignation or death of any Member of the General Medical Council, to cause notice of the same to be sent to the Registrar of each of the Branch Councils.

"2. That the President, on receiving from any of the Bodies entitled to send representatives to the Medical Council, or, in the case of Members nominated by the Crown from the Privy Council, an official notice of the election or nomination of a new Member or of new Members, announce the same to the Registrar of each Branch Council.

"3. That the Registrar summon the person so elected or nominated to the first Meeting of the Branch Council to be held after such announcement, and before the new Member present himself at such Meeting, the President's notification of his election or nomination be read, that he then be introduced to the Meeting by some Member of the Branch Council.

"4. That the same forms be observed in the case of persons who have or have not taken their seat in the Branch Council, when they take their seat for the first time in the General Council.

(Signed) "Andrew Wood, Chairman."

---

14. Moved by Dr Andrew Wood, seconded by Dr Embleton, and agreed to—"That the Report of the Business Committee on the Forms to be observed on the introduction of new Members into the Branch Councils and General Council be received and adopted."

15. Moved by Dr A. Smith, seconded by Dr Corrigan, and agreed to—"That the Registrar be instructed to have the Standing Orders of the General Medical Council printed, and circulated among the Members of the Council."

16. Moved by Dr Andrew Wood, seconded by Dr Corrigan, and agreed to—"That the best thanks of this Council are eminently due, and are hereby offered, to the Royal College of Physicians of London for their obliging and courteous accommodation during the present Session of the Medical Council."

17. Moved by Dr Andrew Wood, seconded by Mr Teale, and agreed to—"That a gratuity of Ten Guineas be given to the Servants of the Royal College of Physicians of London."

A letter having been read from Mr Nussey, intimating his resignation of the office of Treasurer of the General Medical Council,

18. Moved by Dr Storrar, seconded by Sir Charles Hastings, and agreed to—"That the Council record their grateful acknowledgment of Mr Nussey's most valuable services."

19. Moved by Dr Andrew Wood, seconded by Dr Embleton, and agreed to—"That Dr Burrows be elected Treasurer, in room of Mr Nussey."

20. Moved by Dr Andrew Wood, seconded by Dr Embleton, and agreed to—"That the Executive Committee consist of the President, Sir James Clark, Dr Burrows, Mr Nussey, and Dr Acland."

21. Moved by Dr Andrew Wood, seconded by Mr Teale, and agreed to—"That in the event of a vacancy, or vacancies, occurring during the recess in the Executive Committee, they be empowered to elect a successor or successors."

Mr Green having quitted the chair,

22. Moved by Dr Burrows, seconded by Dr A. Smith, and agreed to—"That Dr Stokes take the Chair."

23. Moved by Dr Acland, seconded by Dr Corrigan, and agreed to unanimously—"That Mr Green be elected as President of the General Medical Council."

Mr Green then took the chair, as President.

24. Moved by Dr Andrew Wood, seconded by Dr Embleton, and agreed to—"That the Council now resolve itself into a Committee of the whole Council on Education."

The Council having resumed, Mr Teale brought up the following Report of the General Committee on Education :—

"The Committee on Education, composed of the whole Council, have held several Meetings during this Session of Council, the Minutes of which are herewith presented.

"The Committee recommend the Council to defer for the present the consideration of the subject of the 'Visitation of Examinations,' regarding which the Minutes contain a full Report from a Sub-Committee.

"The Resolutions agreed to by the Committee, which they recommend the General Council to adopt, are as follows :

"I.—General Education and Examination.

"The Medical Council are of opinion that it is desirable,

"1. That all Students pass an Examination in General Education before they commence their professional studies.

"2. That, as far as may be practicable, Testimonials of proficiency granted by the National Educational Bodies, according to the following list, be accepted, with such additions as the Medical Council may from time to time think proper to make :—A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council ; Oxford Responsions or Moderations ; Cambridge Previous Examinations ; Matriculation Examination of the University of London ; Oxford Middle Class Examinations, Senior and Junior ; Cambridge Middle Class Examinations, Senior and Junior ; Durham Middle Class Examinations, Senior and Junior ; Durham Examinations for Students in Arts in their second and first years ; Queen's University, Ireland, two years' Arts' Course for the Diploma of Licentiate in Arts ; Preliminary Examinations at the end of the A.B. Course ; Middle Class Examinations ; Martriculation Examinations ; Dublin University Entrance Examination ; an Examination by any other University of the United Kingdom, equivalent to the Middle Class Examinations of Oxford and Cambridge.

"3. That the Examination on General Education be eventually left entirely to the Examining Boards of the National Educational Bodies recognised by the Medical Council.

"4. That Students who cannot produce any of the Testimonials referred to in the Second Resolution, be required to pass an Examination in Arts, established by any of the Bodies named in Schedule (A) of the Medical Act, and approved by the General Council ; provided that such Examination shall be, in every case, conducted by a Special Board of Examiners in Arts.

"5. That without professing to lay down any complete scheme of General Education for persons intending to become Members of the Medical Profession, the Committee recommend that the scheme of Examination in Arts of the Licensing Bodies be, as nearly as practicable, similar to that of any of the National Educational Bodies above specified.

"6. That after October 1st, 1860, all Medical Students be required to be registered.

"7. That the list of Students registered be closed within fifteen days after the commencement of each Session or Term.

"8. That no Student beginning Professional Study after September, 1861, be registered, who has not passed an Arts Examination, in conformity with Resolution 2 or 4.

"9. That the several Bodies in Schedule (A) of the Medical Act, either jointly or severally, open a Register for Students commencing their Studies in Medicine, in the form annexed.

"10. That the said Register be opened on the first day of each Session or Term, and remain open for fifteen days ; and that within seven days after its close, the Officer in charge be required to transmit a duly-authenticated copy thereof to the Registrar of the Branch Council of that division of the United Kingdom to which the Body or Bodies belong.

"11. That the Registrar of the Branch Council lay the list before the Branch Council, in order that the Branch Council may take whatever steps may seem necessary to secure its accuracy ; and that it thereafter be transmitted, with any remarks by the Branch Council thereon, to the Executive Committee.

"12. That the Executive Committee shall arrange these returns, and publish annually an alphabetical list of the names contained in them.

"13. That the Licensing Bodies shall have power to admit exceptions as to the time of Registration, if satisfactory to them, and shall transmit lists of such exceptions to the Branch Council of the part of the United Kingdom in which such exceptions have been granted, with the grounds stated.

"14. That the various Educational and Licensing Bodies be requested to transmit to the Registrar of the General Council, Returns, embodying any alterations which they may from time to time introduce into their Courses of General Study and Examinations, which qualify for the Registration of Medical Students.

"II.—Professional Education.

"15. That the age of Twenty-one be the earliest age at which any Professional Licence shall be obtained.

"16. That four years of Professional Study be required, after the Examination in General Education.

"III.—Professional Examinations.

"17. That the Professional Examinations be divided into at least two distinct parts ; that the first be not undergone until after the termination of two years of Study ; and the final Examination not until after the termination of four years of Study.

"18. That the first Professional Examination be conducted partly in writing and partly *vivâ voce* ; and that such parts as admit of it be made as practical and demonstrative as may be possible.

"19. That the second Examination be conducted partly in writing, partly *vivâ voce*, and practically as far as may be convenient and attainable.

"20. That the Professional Examinations be held by the several Licensing Bodies (except in Special cases) at stated periods, to be publicly notified.

"21. That Returns from the Licensing Bodies under Schedule (A) be made annually, on the 1st January, to the General Medical Council, stating the number and names of the Candidates who have passed their respective final Examinations, and the number of those who have been rejected."

"The General Medical Council having, in the course of last year, expressed their opinion on the manner in which the General Education of Medical Students ought to be obtained, and stated the principles which appeared to them proper for the regulation of Professional Examinations, consider it undesirable, during the present Session, to enter upon any details upon the so-called higher Degrees and Qualifications.

"But, at the same time, they would record their opinion, that it is not desirable that any University of the United Kingdom should confer a Degree in Medicine, whether that of Bachelor or Doctor, upon Candidates who have not graduated in Arts, or passed all the Examinations required for the Bachelorship in Arts, or the Examinations equivalent to those required for a Degree in Arts."

---

25. Moved by Dr Corrigan, seconded by Mr Lawrence, and agreed to—"That the foregoing Report be adopted."

The Council then adjourned.

Confirmed—Joseph Henry Green.

MINUTES OF MEETING, June 23, 1860.

Royal College of Physicians, London.

Mr Green, President, took the chair, at half-past six o'clock p.m.

Present—Dr Embleton, Dr Andrew Wood, Dr Alexander Wood, Mr Watt, Dr A. Smith, Dr Apjohn, Dr Corrigan, Mr Lawrence, and Mr Teale.

The Minutes of the last meeting were read and confirmed.

Poplar Hospital.—The fifth anniversary of this Institution was celebrated this week at Lovegrove's Brunswick Hotel, Poplar. The subscription list amounted on the occasion to upwards of 1,000*l*.

GENERAL CORRESPONDENCE.

RECIPROCITY OF PRACTICE IN PALL-MALL.

To the Editor of the Medical Circular.

Sir,—Will you allow me to state the following circumstances in your spirited journal? As Mr Headland is again in the field, the Profession is very much interested in what is going on at the College of Physicians at present; it will show you what reciprocity of practice is! I spent five years at the University of Dublin, and took several prizes in Medicine; I am an M.D. of Glasgow University—I resided there two seasons for Medicine; I spent a year at Oxford—(as you have shown it to be) the most insignificant school of medicine in the three kingdoms, but the best school for classics; I took out a year's Practical Midwifery at the Rotunda in Dublin, the best obstetric school in the world; I have two other diplomas, the Hall and College. I have left no opportunity untried to perfect myself as a physician. I went twice to attend the hospitals of Paris and Vienna.

I have been for the last two years Physician, as you know, to a London Dispensary, where I was appointed under a proviso that I should, after a time, join the London College of Physicians; this I did not do, the expense hitherto was so great: but under the recent "year of grace," some one of my medical colleagues at the dispensary—who lives near Brighton!—suggested that as he had joined that august body in London, I ought to do so too, and the Committee of the Dispensary moved and carried a resolution to that effect. Now comes the part that interests your readers who are anxious for that distinction. I sent in my paper to the College, signed by three of the best men perhaps in London; but I heard by a side-wind that I was sure to be rejected, as I was supposed to be favourable or belonged to *a* medical journal; the College were determined not to admit any "Fellows," especially any troublesome Fellows, who might bother them in medical journals. The Dispensary Committee waited a month for the decision; still no answer. Dr Pitman was written to in vain. Then my appointment at the Dispensary was voted to be "forfeited," especially as the College of Physicians would give no reasons for a decision come to, it now turned out, a week before—(learned by accident)—and I had to force Dr Pitman to say whether it were a fact or not that my claim had been rejected. I had not been balloted for at all. I have written again and again, in vain, to be told the reasons which influenced the Board of Censors and Dr Mayo. This, I think, is utterly shameful: five gentlemen will give no reasons, and profess to have none. If this Dr Pitman, their paid secretary, would indicate honestly that it was because I was known to belong to a medical journal, or if he would indicate any reason under Heaven, the Dispensary Committee would reconsider their vote of dismissal; but Dr Mayo, like the King of Naples, seems made of flint. I still beg and entreat of them to state their reasons.

I next offered to go in for examination, to save my dispensary appointment. I was then mystified, or told that I should be an M.D. of Oxford, London, or Durham—save the mark!—but Glasgow would not do. Now, the Medical School at Oxford you have well described as most insignificant. But mark the next stumbling-stone—the examination. I know Italian, French, and German very well; but it was hinted or stated by Dr Pitman, that my examination would consist chiefly of Greek!! which I learned some twenty-five years ago (I am fifty years of age)—ay, and took premiums in, too! But what a farce! what a commentary on what is called "reciprocity of practice!" I would be examined in Greek and pure pathology, and then I should be fit for the dispensary. Now at fifty years, at my age, I would require to "grind" in Greek for six months at least to please Dr Pitman and Dr Mayo; and my hard-earned M.D. at Glagow, that cost me at least 200*l*., is to me so much waste-paper. Even if I did grind in Greek, I am told by one or two Fellows of the College I am sure to be rejected, as having anything to do with journalism: and yet, every public appointment in London requires this degree of Pall mall.

I know another poor fellow, a respectable M.D., with a wife and large family of children, who has gone through identically the same course of snubbing and unfairness at Pall mall, though this "year of grace" was pretended to be a make-weight to make all smooth, and do away with the old cruelty, want of reciprocity in practice: this poor fellow's hospital appointment and bread for his children depend also on whether he knows Greek, Aristotle, or the terrible rubbish of Aristophanes. He is one of the best practical physicians in London, but an occasional writer in journals.

This letter has already stretched to a great length, but it would be incomplete without the following case or corollary—one case out of a dozen of a similar kind—the result of Dr Mayo's conduct, aided by Dr Pitman:

A young lady under my care a year ago, for bad hæmoptysis, with threatened phthisis, a sort of half dispensary patient, got quite well after some steady attention by me to her case. I flattered myself (as indeed it was), that it was a capital cure. More recently (this month) she was frightened, as some one said consumption would still be sure to follow; so she came to me again; but now she learned that I had lost the dispensary, it turned out I was no physician at all. In this strait, she looked about, and she was told of a true physician—one Dr Coffin; and she is now in ecstasies with yarrow-tea and lobelia, under the care of the herbalists' king, Dr Coffin. This fact has been stated to Dr Mayo; it is a fine commentary on the whole matter, and a disgrace to Dr Mayo's College.—Yours, &c., M.D.

P.S.—Is it any wonder that quackery thrives, when honest men struggling as physicians are treated in this manner—every wretched obstruction that old-fashioned Colleges can devise placed in the way of the honest man? Was it any wonder that Jenner hated the very name of this College, as seen by his lately-published correspondence? Some previous magnate of this College also, when Harvey put forward his doctrine of the circulation, was so much of Dr Pitman's mind, that he said in public that he would not give 2d. for Harvey's bills (prescriptions) or discoveries! Men like me do not want to go inside the door at Pall mall; but I ask you, Sir, as the only honest man of our present Medical Editors, is it fair that I am not eligible as M.D. for the poorest dispensary or hospital in London, because College bedels must do all the literary work of the Colleges for the newspapers, and it is thought I might interfere—which I never dreamt of doing—with their proceedings? If Mr Headlam's present Bill should pass, these things will be more provokingly perpetuated.

POOR-LAW MEDICAL REFORM.

To the Editor of the Medical Circular.

Sir,—I should feel obliged by your affording me space in your journal to inform the Poor-law Medical Officers that since the withdrawal of the Bill on Poor-law Medical Relief, I have been in frequent communication with Mr Pigott and the Poor-law Board, and I regret to say there is no hope of any assistance from the latter, as red-tapism reigns paramount, and does not like reform.

I had a long interview with Mr Pigott last Friday in London, and went through every clause in the proposed Bill, when we decided to expunge the coroner's clause, and also that relative to sanitary measures, as a bill on the former subject is now before the House, and we thought it better for the present to leave the health of the community with the Local Boards of Health and the Guardians, and see the working of the Bill just passed the Commons, entitled, "Nuisance Removal and Disease Prevention Bill."

The payment clauses in the proposed Bill will doubtless be severely criticised by those gentlemen who will not gain by them; but I have inserted a clause to exempt all present Medical Officers, who desire it, from coming under its operation, and thus leave them in the enjoyment of their present salaries. To attempt to raise all men to the highest standard now enjoyed would be to ensure a certain rejection of the Bill, and, therefore, I have limited myself to asking for that only which we have a reasonable right to expect will be conceded to us. On trying a variety of modes of calculation, I find the only one that works fairly is that now proposed—viz., 5s. per case up to the first 300 in number, above which 2s. per case only should be paid. In addition to this, a further sum, to be called mileage, is to be paid for all patients requiring to be visited at their own homes; and in order to insure a uniform rate of payment for all the patients in each district, the same mileage shall be paid for each, whether the patient lives next door to the Medical Officer or at the furthest extremity of a district: thus, if the furthest inhabited house in a district be four miles from the residence of a Medical man, then two shillings per case for mileage shall be paid on all those requiring to be visited at their own homes. The Medical Officer of a Workhouse will be paid for his patients on the same plan; but instead of mileage for each case in the Workhouse, he will have one shilling per mile for each visit to the Workhouse. All visits under one mile to be reckoned as one mile, &c. &c. The extra Medical fees are left, as in the last Bill, to be arranged by the Medical Council and Poor-law Board. I have now before me the calculations of nearly all the Unions in England and Wales, and I hope in a short time to complete the rest. These I desire to lay before the Members of Parliament in the form of a pamphlet, and thus show the entire working of the proposed system; but it will depend upon the Profession whether I am to do this or not: at present I have but a few pounds in hand, and must leave the Bill to its fate unless Medical men will come forward speedily and give me the means to set the printers at work. A favourable impression, I am assured, has been made on Parliament, and I know we have in Mr Pigott a zealous advocate of the cause; he works well for the Medical men, because he knows in so doing he will benefit the poor, and what is for their welfare he feels assured is for the benefit of the Ratepayer, and the time will come when the Guardians will view the subject in the same light. In the hope of inducing the Poor-law Board to see the necessity of aiding us in this much-needed reform, I sent them a summary of the calculations of the present and proposed payment in each Union in five whole divisions of the kingdom, with also separate calculations of each Medical Officer's salary in 209 Unions scattered through the Divisions. Hoping the tediousness of looking over these papers might be a little relieved by a few foot-notes, I appended several, of which I give you examples:—"Wolverhampton.—In this Union (the President of the Poor-law Board represents Wolverhampton) the salaries average but 2s. 2d. per case, out of which the Medical Officers have to find the medicines for their patients. The Registrar-General, in his Quarterly Return for April, 1860, writes of this place: 'Several hundreds of the inhabitants are every year disabled by sickness; funerals are a staple trade,' &c. Macclesfield.—In this Union the Guardians pay the Medical Officer of the Workhouse but 3½d. per case, out of which he has to find medicine: the Doctor ought to be a Homœopathic Practitioner. Hexham.—The Medical Officer has a district extending four miles from his residence, and yet he has a salary which, divided amongst his patients, gives an average of only 6½d. per case, out of which he has to find medicines, horses, &c. No wonder 'Punch' writes 'Pill-grinders for Paupers.' Birmingham.—The Guardians find the medicines for the Workhouse at a cost of 1s. 11d. per case; and yet they only pay their six District Medical Officers, who find their own medicines, a salary which averages 1s. 8½d. per case." I offered to send the Board a continuation of my calculations, but on the 5th of this month I received the following communication: "The Board do not desire to impose upon you the trouble of sending to them any further calculations, and they return with this letter those already forwarded for the information of the Board."

Before this is in print, I hope you will have seen by the daily papers that the Bill has been introduced; if not, it doubtless will be before long; but it has to be put into legal form, which may delay it a short time. The expense of this will, I fear, leave me penniless.

I am, &c., Richard Griffin.

Poor-law Medical Reform Association,
12 Royal terrace, Weymouth,
9th July, 1860.

P.S.—As soon as the Medical Officers see the Bill is introduced into the House, I hope they will petition in its favour, and do all they can with their Members.

MEDICAL TITLES.

To the Editor of the Medical Circular.

Sir,—There seems to be a notion prevalent among a certain class of the Profession that none can be a Physician unless he be a graduated Doctor of Medicine of a University: hence their desire to have the charter of the Royal College of Physicians altered to the effect that a person may become a Licentiate in the College of Physicians without being able to call himself a Physician; a gross absurdity in terms, as you remark; for if this can be effected, it will be as likely that a person may be a Licentiate of the College of Surgeons without being a Surgeon.

But this notion proceeds on the ground that none can make Physicians but Universities. Now, let me say that the title of Doctor created by a University is but of recent date comparatively. "It seems to have been established for the Professors of the Roman Law in the University of Bologna, about the middle of the twelth century. Antony à Wood says that the title of Doctor in Divinity began at Paris after Peter Lombard had compiled his Sentences, about the year 1151." (*a*) Then let me ask, who were the Physicians before the twelfth century, before there were University Doctors? It may be answered, the "Masters of Physic" of the Universities. But let me ask again, who were the Physicians before there were Universities? The first University in Britain was Oxford, which is said to have been founded in An. 872, and the title of Doctor was not adopted in the English Universities earlier than the time of John or Henry the Third. (See Hist. and Antiq. Univ. of Oxford, 4to, Oxf., 1792, vol. i, p. 62.)

Now, Sir, let the Doctors tell us who made the Physicians before there were Universities; who made the *Iatroi* of the Grecians, and the *Medici* of the Romans; who made the Physicians of the civilised nations of Europe before there were any Universities. Let me say still further, that when the title of Doctor was created by the Universities, and for long after, it was kept to its original meaning—that is, "a teacher,"—and it was given to none but to teachers. The University Degree of Doctor of Medicine pronounced the person as qualified to teach the science of Medicine, and was given to none but to Professors of the Universities at first; but after the sixteenth century this rule seems to have been broken through, and soon the Doctors became so numerous that all could not be teachers, and the title so common that it did not distinguish the teachers from those who did not teach, so that the title of "Professor" was created to distinguish the latter. But what became of the ancient *Medici*, the Physicians, all this time? The Physicians, you will observe, previous to all these innovations, were the teachers as well as the practisers of Medicine. (*b*) The title of Doctor of Medicine was created to distinguish between the teachers and practising Physicians; but now the title of Doctor of Medicine being applied, not to the teachers but to the practisers of Medicine, and having become so numerous, and their title so common, they wish the ancient Physicians to be annihilated, and themselves to have the exclusive claim to the title of Physician. Now, you will observe farther that the ancient Physicians had the exclusive claim of practising Medicine (by charter), and that the University Doctor held only the honorary title of Doctor, and had no right to practise until he became a Licentiate of the College of Physicians. The Medical Act, however, gives the Doctor of Medicine a legal right to practise which he had not before. But I have to remark farther, that the moment the Doctor of Medicine descended from his chair and became a practiser of Medicine, he put himself again in the place of an ancient practising Physician, and his title of Doctor became no longer the distinguishing title of a teacher; Professor was substituted, and "Doctor" now distinguishes all practising Physicians. But now they tell the pure Physician, "You have no right to the title." He answers, "The English language has so appropriated the title, and custom and judical decision has legalised it; and if the Physician has no right to the title of Doctor, the Doctor has no right to the title of Physician. The Physician has as good claim to the exclusive title of Physician as the Doctor might think he has to his own." Such is the history. Inch by inch the privileges of the ancient Physician have been encroached upon, and now they want him extinguished altogether. But if the title of Physician be extinguished, it is but justice he should have the rights, privileges, and title of the practising Doctor, who has assumed his place.

Please let your readers know as much of this history as you think proper, and you will oblige your obedient servant, MEDICUS.

P.S.—I see that the Committee of the Medical Council, in their Report on their proposed Amendments of the Medical Act, propose that Sect. XL be altered so as to prevent non-graduate Licentiates of the College of Physicians from using the title of Doctor. I hope it will have the effect of also preventing the Doctors of Medicine, not Licentiates of a College of Physicians, calling themselves Physicians.

(*a*) The title of Doctor of Medicine must have been later in being created.

(*b*) The title of Physician does not flow from the Doctor of Medicine, but that of Doctor of Medicine flows from the Physician.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

Wednesday, July 4, 1860.

Dr Rigby, President, in the Chair.

Dr Harley exhibited (for Dr Newman, of Fulbeck) a fœtus of about four months, which had been retained *in utero* for some weeks after its death.

Dr Drage gave a description of a case of

EXTRA-UTERINE PREGNANCY.

An opening formed between the fœtal cyst and the vagina, through which a number of bones were extracted. The woman ultimately recovered.

Mr Joseph Thos. Mitchell read a paper on

SOME OF THE EXIGENCIES CONNECTED WITH PRETERNATURAL LABOUR.

The Author commenced his paper by referring to the ill consequences which often follow the too strict adherence to the axiom in midwifery, that "meddlesome midwifery is bad midwifery." He set this forth by alluding to the history of cases that had come under his notice, in which the lives of some women had been placed in jeopardy, and the future comfort of others had been permanently destroyed, as well as of other cases, in which children had been born dead, whose lives would most probably have been saved had early manual or instrumental aid been applied. He then alluded to his strong objection to the use of the crotchet in cases of craniotomy, and his custom in such cases to rely alone on the craniotomy forceps for delivering, relating a case that occurred in an extremely narrow pelvis, in which the practitioner obstinately refused to use the embriotomy forceps, and would depend alone on the former instrument, by which he extensively lacerated the vagina, in consequence of its often slipping off from the head during the operation, which case terminated in the death of the woman, undelivered; the uterus having been ruptured, and the child having passed into the abdomen, when in all probability, had the embriotomy forceps been used, delivery would have been safely effected, as it had been on a former occasion. He next referred to the culpability which rests on every practitioner who undertakes to attend on any woman in her second or subsequent labour, who had previously been delivered by embriotomy or by the forceps, when the child had been born dead, without inducing premature labour between the seventh and eighth, or at the eighth month of gestation, as the nature of such former labours might seem to indicate. He related a remarkable case in which a practitioner had neglected so to act, and the complicated difficulties which followed, requiring the dismemberment of a very large child at the full period of gestation. The abdomen and chest were eviscerated, and then the lower half of the body was removed at the fourth dorsal vertebra, by which alone room could be obtained to reach the arms and head. The patient did well. She afterwards came under the Author's care, and was delivered safely at premature periods on four different occasions, twice with great difficulty at seven months and a half gestation, and subsequently twice at six months and a half, on each occasion by inducing labour by puncturing the membranes, for which purpose he adopted a peculiar instrument, which he exhibited to the Society, and which instrument he had found useful also in rupturing the membranes in cases of placenta prævia attended with extreme circumstances. The instrument was made by Messrs Millikin and Lawley, of the Strand. In the course of the relation of this case, the Author stated that, on the occasion of the third labour, at seven months and a half gestation, when the head presented, delivery was effected by the forceps, and a child was born that lived fourteen hours; and on that of the fourth accouchement, at the same period, when the arm presented, the woman could not be delivered except by dismemberment of the child. From these circumstances he deduced the conclusion that it was not wise to adopt the modern recommendation of delivery by turning in cases of small pelvic brims, whenever delivery can be effected by the forceps, as by that means a far greater chance would exist of delivering a living child than when turning is adopted. By the latter mode, the protracted pressure unavoidably made on the funis, as the head is passing through the brim, is almost certain to occasion the death of the child; and in cases also where delivery can be effected by craniotomy, it is accomplished with less distress to the mother than by turning. The Author also referred to the fatal consequences to children which often follow doubtful or incorrect diagnosis of presentations in early labour, especially in cases where delivery can only be effected by turning, which he showed in the history of a case in which there was the presentation of the abdomen, with the child doubled up, the head resting on the sacrum, and the hips on the pubis. In this position the practitioner allowed the case to remain for nearly three hours, not knowing the character of the presentation, and what it necessitated, the woman all this time suffering under violent expulsive labour, by which the child was killed; whereas, had turning been adopted at the commencement of this period, which would then have been a perfectly easy operation, the os uteri being then fully open, the child would, doubtless, have been born alive.

Dr Priestley thought that the Society was much indebted to Mr Mitchell for his practical paper, and he believed it would be very advantageous if other gentlemen would record their mistakes and occasional failures, instead of only relating their successful cases. He quite agreed with Mr Mitchell in his denunciations against the crotchet, which he considered a most unsatisfactory instrument; and hence he very generally resorted to the use of craniotomy forceps in the place of it. He considered that Mr Mitchell had increased the difficulty of delivery in one of the related cases by amputating the lower half of the child's body, by which means he had deprived himself of the power of properly employing traction.

Dr Rigby stated that the crotchet certainly did not fulfil the wishes of those who were obliged to employ it. This instrument was always apt to slip; and when it did so, there was great danger of its injuring the soft parts of the maternal passages, or the fingers of the practitioner.

Dr Tanner mentioned that, in two cases of more than usual difficulty, he had found Dr Oldham's small hook of great service in aiding delivery. He confirmed the remarks of the previous speakers with regard to the crotchet.

Dr Waller said that his old teacher always alluded to the crotchet as an atrocious instrument. For his own part he never used it, except by passing it up outside the head; and then sometimes by fixing it in the orbit, he got a good and serviceable hold. He mentioned a case of great difficulty where he had used the craniotomy forceps successfully, when the crotchet was quite useless.

Dr Barnes did not rise to defend the crotchet, but still he had had more success with it than many other Fellows of the Society seemed to have had. In Dublin the most eminent obstetricians use the crotchet, and with success. He had employed Dr Oldham's hook, and found it answer very well. He thought that the Author was wrong in assuming that turning ought to be discarded in cases of contracted pelvis. He believed there were instances when the only resource was craniotomy or turning—the forceps could not be used: in these he had succeeded in

safely effecting delivery, both for mother and child, by turning.

Dr J. Braxton Hicks read an Appendix to a paper on

CONCEALED ACCIDENTAL HÆMORRHAGE.

This was an addition of eleven cases to the ten already described; the majority not having been published, the Author was indebted to the gentlemen whose names were mentioned with each report. These cases, it was observed, might be concealed totally till death or the termination of labour, or temporarily for a longer or shorter time. During the non-appearance of hæmorrhage externally, the diagnosis of the case was as difficult as when wholly concealed. After reporting the cases, an analysis was given, showing that fifteen died and six recovered; and that it was much more fatal at full term than at any other period. The diagnostic symptoms were then pointed out, —namely, 1st, severe fainting or collapse; 2nd, the enlargement and doughy feel of the fundus uteri, the outline of the fœtus being lost, and very frequently a sensation as if about to burst; and, 3rd, in nearly every case the absence of true labour-pains. These, taken together, were held sufficient to point out the true nature of the accident. When no pain was present, the state was very liable to be mistaken for ordinary syncope; and the Author urged that in all cases of severe and protracted faintness during the latter months of pregnancy or labour, the state of the uterus should be carefully watched. It was also advised that the same treatment as is now adopted in all ordinary accidental hæmorrhage should be employed as early as possible in this form, though the usual good results could scarcely be expected, because, although the contents of the uterus were thereby diminished, yet as the effused blood, being bound down by the placenta, prevented the uterus from contracting at that part, the bleeding sinuses were kept patent. This was borne out by the analysis of the twenty-one cases.

Dr Tanner stated that he had recorded a case of concealed accidental hæmorrhage, which had escaped the notice of the Author of the paper. The communication was to be found in the 'Medical Times' of October 18, 1851. In this instance the separation of the placenta was due to a violent fall; and the patient would doubtless have died, had not the labour been hurried, and the delivery effected by the forceps. As it was, large quantities of stimulants were required, and the infant was still-born.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—Tuesday, July 10.

DR MACLOUGHLIN.

Mr Brady moved for a Select Committee to inquire into the dismissal of Dr Macloughlin from the Government Medical Service. The hon. member, after detailing the requirements of the Medical Services, said Dr Macloughlin entered it under the existing circumstances, and was sent to Portugal, where he rendered most efficient services, not only to their own soldiers, but to the French prisoners during the Peninsular war. He trusted the Government would grant him the Committee, as Dr Macloughlin had laboured for a number of years in the service of the army. The hon. Member read testimonials from Sir Jas. M'Grigor, Sir Robert Grant, and others, to the ability of Dr Macloughlin, and said that after returning to this country he was recommended by the late Duke of Wellington and Sir Robert Grant for promotion, but in consequence of having no private influence he could not obtain that recognition for promotion which his services deserved. Notwithstanding all he had done, a Mr Lyons, without experience or a particle of qualification, was raised over the head of a man who had faithfully served his country. Dr Macloughlin, indignant at the treatment he received, remonstrated with the Horse Guards, and, contrary to his wishes and inclinations, he was placed on half-pay, upon which he remained for six years without ever being called upon to serve. At the end of six years he was called upon to serve, but under what condition? Why, that he should serve under about 200 others, junior to him, who had been appointed to active service during the time that Dr Macloughlin had been on half-pay. He then declined to enter into active service unless his previous services were acknowledged. He (Mr Brady) found that in consequence of Dr Macloughlin declining to go on active service, he was dismissed by the Commander-in-Chief from the Service. In this case the articles of war were altogether ignored and set at nought; and although Dr Macloughlin had complained of his superior officer from 1814 to 1824, the articles of war were entirely disregarded.

At this stage of the proceedings an hon. Member moved that the House be counted, upon which some members came into the House, and as soon as the required number was made up they as rapidly departed, leaving the House as empty as it was before.

Mr Brady resumed. He contended that Dr Macloughlin's dismissal was not only unjust, but illegal. The Commander-in-Chief stated, through the medium of Sir Charles North, that he saw no reason why Dr Macloughlin should not be reinstated, if Lord Panmure, who was at that time Secretary-for-War, would assent. That assent was withheld, and Dr Macloughlin, who had made a renewed application to the War Office, was still without redress. He therefore begged leave to move that a select committee be appointed to investigate the case.

Sir G. Bowyer seconded the motion.

Mr S. Herbert said all the persons who could have given evidence on this case were dead, and he therefore thought that a committee ought not to be appointed. It was admitted that Dr Macloughlin refused to enter upon active service when called upon to do so. Such insubordination would be disgraceful to any officer in the army, however respectable he might be; and the authorities acted rightly in dismissing Dr Macloughlin from the Service. Mr Alexander, as well as the present Surgeon-General, protested against Dr Macloughlin's reappointment, on the ground that it would be an exceedingly bad precedent. If Lord Panmure, while Secretary-for-War, acted unfairly in refusing to listen to the appeal of Dr Macloughlin for redress, he had certainly many *particeps criminis*, for amongst those who took the same view as the noble lord were Sir Henry Hardinge, Lord Francis Gower, Sir E. Parnell, Sir Thomas Fremantle, Mr Fox Maule, and Mr Vernon Smith. He hoped the House would not agree to the motion.

The motion was negatived without a division.

Births, Marriages, and Deaths.

BIRTHS.

Currie.—July 6, at Queen's terrace, Bayswater, the wife of Samuel Currie, M.D., Deputy Inspector-General of Hospitals, of a daughter.

MacFarlane.—March 14, at Sydney, N.S.W., the wife of the Hon. John MacFarlane, M.D., of a daughter.

Newham.—July 6, at Western House, Winslow, Bucks, the wife of Thomas Newham, M.D., of a daughter.

Scott.—July 9, at Portland villas, Plymouth, the wife of R. T. C. Scott, Esq., of Melby, Zetland, Staff-Surgeon R.N., H.M.S. 'Impregnable,' of a daughter.

MARRIAGES.

Allinson—Farnfield.—July 4, at St Margaret's Church, Lee, John Allinson, Esq., M.R.C.S., of Spital square, London, to Anne Charlotte, eldest daughter of S. Farnfield, Esq., of Wood street, Woolwich.

Tayler—Heale.—July 10, at Cross Church, Winchester, Captain Francis Tayler, of the Royal Military College, Sandhurst, to Eliza, second daughter of J. N. Heale, M.D., of Winchester.

DEATHS.

Carson.—June 17, at the residence of Mr Milroy, in Hamilton, the Hon. Samuel Carson, M.D., Member of the Legislative Council of Newfoundland.

Gallagher.—At Lamhaquqoe, Peru, Hugh Moss Gallagher, M.D., L.R.C.S. Ireland, of Letterkenny, County Donegal.

Moffit.—July 5, at Howdon-on-Tyne, Northumberland; William Moffit, L.S.A. Lond., aged 64.

Rodham.—July 3, auddenly, Richard Rodham, of Sunderland, formerly of Wreath, Yorkshire, aged 43.

Schofield.—May 21, at Brockville, Canada, Dr Peter Schofield, aged 74.

Torr.—June 29, at Barnstaple, Devon, Thomas Berry Torr, M.R.C.S. Eng., L.S.A. Lond., aged 55.

Van Oven.—July 9, at 22 Manchester square, Barnard Van Oven, M.D. Jena, M.R.C.S. Eng., L.S.A. Lond., aged 64.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, July 5th, 1860:—Matthew Blackman, M.R.C.S., Ramsgate; Danvers Ward Bush, Weston, near Bath; Edward Strickland, Kirby Moorside; Edgar Beckit Truman, Poultry, Nottingham.—The following gentlemen also on the same day passed their first examination:—Samuel Armstrong, Woodbridge, Suffolk; Charles Addams Buckmaster, King's College; Stonard Edye, Exeter; H. Dowling Ellis, St Bartholomew's Hospital; Chas. Walter Elwes, University College; Edwin Broughton Fenn, Ardleigh, Essex; Henry Grenfell, King's College; William Froude Langworthy, St Bartholomew's Hospital; Thomas Martin; Manchester School of Medicine; William Henry Julius Murrell, St Bartholomew's Hospital; John Dee Shapland, University College; Thomas Starkey Smith, University College; William Stephenson, St Bartholomew's Hospital; Henry Sutcliffe, University College.

Soiree at the College of Physicians.—On Wednesday evening a brilliant and crowded *conversazione* was held at the College of Physicians. Many objects of scientific interest were exhibited. Amongst them we would especially notice the excellent microscopes of M. Nachet, of Paris, who also contributed an ophthalmoscope, which is said to be the most perfect example of this instrument yet made.

Middlesex Hospital.—The annual Distribution of Prizes took place in the Board-room of this Hospital on Thursday, the 21st ult.,—the Right Hon. J. T. Coleridge in the chair. The proceedings opened with a report from Mr Nunn, the Dean of the College, who gave a very favourable account of its condition, and expressed the thanks of the professors to the governors of the hospital for their liberality in making the extensive enlargements and improvements, which are now nearly completed. The names of the successful candidates were then read by the Hon. Secretary to the College; after which the Chairman gave an address full of excellent advice to the students, founded in great measure on his personal experience in his own profession, which was cordially and warmly applauded by a crowded audience. Thanks to the chairman were then moved by the Hon. Capt. Maude, and carried by acclamation. *Summer Session*, 1859.—Prizes and Certificates of Honour awarded to First Year's Students.—Mr F. W. Spurgin, first prize; Mr J. Harper, second prize.—Materia Medica: Messrs J. Harper, F. W. Spurgin, and T. Gambier.—Botany: Messrs F. W. Spurgin, W. N. Marshall, R. P. Tyley, and A. D. Hunt.—Practical Chemistry: Mr F. W. Spurgin. *Winter Session*, 1859-60.—Messrs W. Eagles and W. D. Spanton, prize (equal).—Anatomy: Messrs E. Morgan, W. Eagles and W. D. Spanton (equal), R. Frean and A. J. Newman (equal), and C. P. Langford.—Physiology: Messrs W. Eagles and W. D. Spanton (equal), C. P. Langford, R. Frean, and E. Morgan.—Chemistry: Mr. R. Frean. *Summer Session*, 1859.—Prizes and Certificates of Honour awarded to Second Year's Students.—Mr T. Jones, first prize; Mr R. Wrixon, second prize.—Midwifery: Messrs T. Jones, R. Williams, R. Wrixon, and W. J. Bonnor.—Forensic Medicine: Messrs T. Jones, W. J. Bonnor, R. Williams, and R. Wrixon. *Winter Session*, 1859-60.—Mr F. W. Spurgin, first prize; Mr W. R. Elsdale, second prize.—Medicine: Messrs J. Harper, F. W. Spurgin, W. R. Elsdale, and J. M. Phillips.—Surgery: Messrs F. W. Spurgin, W. R. Elsdale, J. M. Phillips, and J. Harper.—Anatomy: Messrs F. W. Spurgin, J. M. Phillips, J. Harper, R. P. Tyley, W. N. Marshall, and J. E. Bennett.—Physiology: Messrs W. R. Elsdale, W. N.

Marshall, F. W. Spurgin, J. Harper, J. E. Bennett, and J. M. Phillips.—Prizes to Third Year's Students.—Mr F. H. Watts, first prize in Clinical Surgery; Mr J. Walker, second prize ditto.—Mr T. Jones, Governor's Prize, for the best Reports in Clinical Medicine and Clinical Surgery.—Mr J. Harper, prize offered by the Medical Society for the best paper of the Session.—Messrs F. B. Bell, T. Dane, F. B. Fowler, S. Hayward, T. Jones, T. H. Muncaster, C. H. Rason, J. Walker, R. Williams, and F. H. Watts, Honorary Certificates of general Good Conduct and Diligence.

Militia Surgeons.—Mr Sidney Herbert received a deputation at the War Office on Friday, the 6th inst., when the subjoined requisition, signed by 47 colonels of regiments, and 109 members of the House of Commons, was presented. The following members attended:—Lord Burghley; Colonels the Hon H. B. Bernard, Sir E. Lacon, Sir James Fergusson, Dickson, Vandeleur, and Forde; Major Edwardes, Sir H. Stracey, Capt. Gladstone, Capt. Esmonde, and Mr Beamish. Several other noblemen and gentlemen of the House of Commons had promised to attend, but in consequence of two previous postponements they were prevented doing so. Lord Burghley introduced the deputation, and, after reading the requisition, made some forcible remarks upon the justice and economy of placing the surgeons of militia regiments upon the staff of their respective regiments. He informed Mr Sidney Herbert that, besides those who had signed the requisition, 71 more members of the House had promised to vote for any motion which might be introduced for that purpose, and 30 more colonels were favourable to the step. He then introduced the following militia surgeons: G. B. Childs, Esq., Royal London; J. F. Nicholls, Royal Wiltshire; Dr Barr, and Dr M'Cormack, which latter gentleman, as the representative of the militia surgeons generally, entered very fully and forcibly into the anomalies and injustice under which the service suffers, and showed, from returns carefully prepared, the great saving to the country that would be ensured by placing these gentlemen on the staff. Mr Herbert gave the statement a most careful and patient hearing, but declared his unwillingness to come to any decision at present, as the case was of too important a nature to do so; he, however, promised in a few days to give his answer to Lord Burghley. The deputation, having thanked Mr Herbert for his courtesy and attention, then retired. The following is a copy of the requisition above referred to:—"To the Right Hon the Secretary of State for War. We, the undersigned members of the House of Commons, and colonels of militia regiments, beg respectfully to direct the attention of the Secretary of State for War to the present unsatisfactory position of militia surgeons. In consideration of the valuable services rendered from time to time by these officers during the embodiment of their regiments, and in consequence of the continued duties required of them during the disembodiment of their corps; being also compelled by Act of Parliament to reside at their respective headquarters, and unable (as they have proved before the Royal Militia Commission) to obtain any public appointment, or any amount of private practice, owing to their liability at all times to be called away for active service; a majority of these gentlemen having also served during two embodiments, extending over a period of from four to five years, which in the regular service would entitle them to permanent half-pay; and as the remuneration at present granted to them is insufficient in amount and uncertain in its character; and having carefully considered their case,—we respectfully urge upon you the justice and propriety of introducing into the contemplated Bill for improving and reorganizing the militia a clause placing these officers upon a more permanent and remunerative footing."—(Here follows a list of colonels of regiments and members of Parliament who have signed this requisition.)

Insolvent Debtors' Court, July 7th.—In Re J. O. Wray.—The insolvent, a young man who described himself as a patent medicine vendor, trading as "Henry and Co.," appeared for judgment. The case was before the Court on the previous day, when a novel point of opposition was raised. Mr Sargood opposed on the part of a young man, and Mr Dowse supported. It appeared that the insolvent, who is now only twenty-five, had purchased in 1856 a business in Dorset street, Dorset square, of a Mr Henry. He had carried it on as "Henry and Co.," and had adopted pamphlets issued in the name of "Dr Henry," in which relief was promised to thousands, and the doctor was described as "A.M.," and also as a member of the College of Surgeons. Mr Sargood contended that the petition must be dismissed. His client had paid a fee which he was ordered to refund. Seeing the way in which the insolvent had appeared before the world, it was not sufficient to say he had dealt in quack medicines. Mr Dowse instanced the case of a young man named Sutton, who was required to amend his description, and his petition had been sustained. Mr Commissioner Nichols, on the former hearing, said he would consider the point, and now he said the petition must be dismissed; and if the insolvent should again petition, he must take care and insert the appendages he had used to the name of "Henry," or his petition would share the same result. The protection petition was ordered to be dismissed.

The Liverpool Poisoning.—On Monday morning last the prisoner Thomas Winslow, charged with poisoning the late Mrs James, of Liverpool, by the administration of antimony, was again brought before the local stipendiary, Mr T. S. Raffles. Mr Walters, prosecuting solicitor, stated that, in consequence of the investigation having assumed a much more serious character than was at first anticipated, it was desirable to have a further remand, as poison had been found in each of the bodies which had been exhumed, and it would be necessary to obtain the evidence of the most expert and scientific analysts. To do so would require a fortnight. Mr Raffles remanded the prisoner in the meantime for seven days. The bodies which have been exhumed are those of Mrs Townsend (sister of the late Mrs James) and her two sons Samuel and William.

A Fatal Passion for Hanging.—A lady, inhabiting a pretty little house near Paris, possessed of ample means, of a charitable disposition, and very fond of reading, writing, and purchasing books, was found hanging the other day. She left a document of an extraordinary character, in which she stated that, no sooner had she determined upon hanging herself than she executed the deed. She always had a remarkable predilection for people who had been hanged, and she left in her library a manuscript in which she had inserted accounts of all celebrated persons who had been hanged; and in another MS. all the proverbs and sayings concerning hanging were collected. "Hitherto, however, the idea of hanging myself had not entered my head, but becoming *ennuyed*, and having lost my taste for everything, even for my favourite pastime of reading, the idea of suspension has occurred to me, and as soon as I have completed this note, I shall put it into execution. I desire that the rope I employ may be divided between my two neighbours, and that all my property be realised: First of all, a pension of 40*l.* must be reserved for my old servant, and then all that remains must be so disposed of as to produce ten equal portions, which are to be distributed to the first ten poor families, one of the members of which may happen to hang himself, dating from the day of my death. This is my sole will and testament."

Quarterly Return of the Mortality of the Metropolis.—In the thirteen weeks ending Saturday, June 30th, the total number of 14,894 deaths was registered in London. The mortality was high, for in the corresponding quarters of the four years 1856-9 the numbers ranged from 13,252 to 14,541. That this result was due to unseasonable cold will become apparent when it is stated that, whereas the mean temperature of the air in any of those four quarters was not lower than 52·3°, and in those of 1858-9 exceeded 54°, the mean temperature of the quarter now terminated was only 50·5°. As a consequence of the cold, the deaths from pulmonary diseases, exclusive of phthisis and whooping-cough, rose from 1,974 in the June quarter of 1859 to 2610 in the last quarter. Phthisis was also fatal: it increased from 1993 deaths to 2133. Whooping-cough was rather more fatal than it had been in the same quarter of 1859, but in a much less degree than in those of 1857-8, when the mean temperature was much higher. As might be expected under atmospheric influence, to which all persons are exposed, and of which all more or less are susceptible, the mortality from diseases generally was increased. But there was a perceptible decrease in the aggregate of zymotic complaints, which in two previous spring quarters caused 3604 and 3135 deaths, and last quarter 2917. Though fatal cases of small-pox (240) were numerous, yet they scarcely exceeded those of the same period in 1859. Of the 240, exactly a fourth part occurred at twenty years of age and upwards. Measles, from which 568 young persons and 3 adults (at twenty years and upwards) died, was more fatal than any other zymotic disease. Scarlatina carried off 356 persons, and diphtheria 107; they were both considerably less fatal than in the same quarter of last year. Diarrhœa also exhibited a marked decrease on that of previous springs; and no death from cholera was returned. 5 persons died from privation, 89 infants from want of breast-milk, 15 persons (chiefly young) from purpura and scurvy, 32 from delirium tremens, 24 from intemperance. Deaths from heart disease rose to 685; those from bronchitis to the unusual number of 1456. There were 80 suicides in the quarter.

APPOINTMENTS FOR THE WEEK.

Wednesday, July 18.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, July 19.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2½ p.m.

London Home.—2 p.m.

Friday, July 20.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, July 21.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, July 23.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, July 24.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

A Poor-law Surgeon.—The Bill has not yet been introduced: we cannot tell whether the clauses relating to the appointment of two Medical Officers to one district will be in the Bill or not.

B. B. (A Metropolitan Medical Officer) wishes to know if "the new Poor-law Medical Relief Bill has received the sanction of the Profession?" We hope the Medical Officers will wait patiently until the Bill is before them. There will be plenty of time to study its provisions. We think it quite time that something was done. Read Mr Griffin's letter in this week's Circular.

M.R.C.S.—1st. No.—2nd. Dr Acland, Dr Rolleston, and Dr Ogle.

Mr John H.—1st. Yes.—2nd. Forwarded.

Medicus.—The new theory of natural selection is really a very old one, the name alone being new. The subject is ingeniously treated by its advocate. The theory means, that certain individuals of a race being placed in favourable conditions not enjoyed by other members of the race, will develop in some extraordinary way, until, in succeeding generations, they become importantly different from the original type. This is essentially the doctrine of external causes acting upon and modifying race.

Gamma.—We are unable to comply with your request.

Mr Wood.—It shall be attended to.

Mr H. Evans is thanked.

A. Z.—Case received. The publisher will write to you.

A Student.—Yes; from the date of apprenticeship.

Mr Wilson.—Send to Millikin and Lawley's in the Strand.

Dr J. B. Nicolson's communication has been received.

Mr Henry W.—The College has no power in such circumstances.

O. F.—Yes.

Mr G. K. H. Paterssen.—Note received. A private letter shall be sent.

M.R.C.S. (Bradford).—Your request shall be complied with.

Letters received from Dr E. Cronin, E. Lyon, C. Enright, B. F. Matthews, Dr R. Crothers, S. W. Sproulle, R. G. Buckley, Dr Nottingham, R. P. Roberts, J. A Young, W. Meadowcroft, B. W. Brwon, &c. &c.

Chlorodyne. — R. Freeman,

Pharmaceutist, Kennington road, London, S., informs the Profession and Trade that he has FOR YEARS MADE, and extensively used in his business, Chlorodyne; and that he is supplying it in one-ounce stoppered bottles at 1s.6d. each, and in four-ounce bottles, 6s. each. He guarantees it to be uniformly and properly prepared, and superior to any other makers', though their charge be ever so exorbitant; and he trusts that the lowness of price at which he offers it will allow the Profession to use it in common practice and at public institutions, so that its extraordinary beneficial effects may be enjoyed by the poorest sufferer. Sold by all Wholesale Druggists.

Important to the Medical PROFESSION.

GLOVER and Co., Wholesale Druggists, are supplying GENUINE DRUGS, CHEMICALS, and PHARMACEUTICAL PREPARATIONS of first-class quality at a very low figure.—Price Lists may be had on application,

GOODGE STREET, LONDON.

Flour — (Essex) — Warranted

free from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs), 11s.; Households (recommended for bread-making), 10s. 4d.; Seconds, 9s. 8d.; Wheat Meal for brown bread, 9s. 8d. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 97 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any rail station 200 miles. German Yeast.

Diphtheria, Clerical Sore-Throat,

Loss of Voice, and other diseases of the mucous passages of the throat, successfully treated with Solution of Caustic by Tompson's Patent Hydro-Pneumatic Inhaler (easy of self-use), without pain or inconvenience. To be seen at the Industrial Exhibition of Society of Arts, Adelphi (Art. 155), and the Agents, Milliken and Lawley, Surgical Instrument Makers, 161, Strand, adjoining King's College, London.

Kamptulicon Floor Cloth,

warm, noiseless, indestructible by damp, extensively used at the Houses of Parliament, Somerset House, British Museum, Museum of Patents, South Kensington Museum, and the Great Eastern, and especially adapted for Hospitals, &c.—E. GOUGH and Co., Original Manufacturers and Patentees, 12 Bush lane, London, E.C.

Pure Country Milk and CREAM.

—Messrs EDMONDS and BAYNES, OXGATE FARM, WILLESDEN, have received the most flattering testimonials from several eminent Members of the Medical Profession in favour of the purity and freshness of their MILK and CREAM, which they undertake to supply Twice Daily to any part of the West-end. Orders received as above, or at the Office, 16 Marchmont street, Russell square; and at St Petersburgh place, Bayswater, W.

CREAM being now recommended as a substitute for COD-LIVER OIL, Messrs E. and B. beg to inform the Profession that they can supply it in any quantity with punctuality.—A prospectus free by post.

Galvanic Institute,

52 Euston road.

These rooms have been opened under the superintendence of registered qualified Medical Men, for the legitimate application of Galvanism in the treatment of Nervous Diseases, Paralysis, Rheumatism, Asthma, Indigestion It will also assist in affording the means of taking this branch of practice out of the hands of the unqualified. Hours of attendance twelve to five (Sundays excepted).

Ordinary Medical Attendant, Mr J. Smellie, Surgeon

TO THE PROFESSION.

Messrs M'Gowan & Danks

(THE PRINTERS OF THIS JOURNAL)

Are prepared to forward Estimates, to those requiring the same, for any description of Work connected with the Printing Business.

Messrs M'G. and D. are enabled, from the facilities which they possess, to execute whatever may be entrusted to them with economy and despatch.

Letters addressed to No. 16 GREAT WINDMILL STREET, HAYMARKET, will meet with immediate attention.

*** There is at the present time an opening for the Printing (and Publishing if wished) of a Weekly Periodical.

WATER BEDS. EDMISTON AND SON,

5 CHARING CROSS (LATE 69 STRAND),

Beg to call the particular attention of the Managers of Hospitals and Dispensaries, and the Medical Profession generally, to the price and quality of their Hot or Cold Water Beds.

WATER BEDS, according to size, £4 4s., £5 5s., and £6 16s. 6d.

Water Cushions, all sizes, from 7s. 6d. to 30s. Cotton Elastic Stockings, 4s. 3d.; Silk, 5s. 3d. Knee-Caps, Leggings, Anklets, &c. Day and Night Urinals, from 3s. 6d. to 12s. 6d. Injection Bottles, Bed Sheets, Accouchement Belts, &c.

India-Rubber Chamber Utensils for Lunatic Asylums, 7s. 6d. each, or 75s. per dozen.

INDIA-RUBBER MATS AND SOUNDLESS ELASTIC FLOOR-CLOTH.

Water Beds can be had on hire. Terms 7s. 6d. per week.

LONDON: EDMISTON AND SON, THE POCKET SIPHONIA DEPOT, 5 CHARING CROSS (LATE 69 STRAND).

LEVER ESCAPEMENT.

Benson's Watches. "Perfection of Mechanism."—'Morning Post.'

Gold, 4 to 100 guineas. | Silver, 2 to 50 guineas.

Send two stamps for Benson's Illustrated Watch Pamphlet.

Watches sent free to any part of the Kingdom on receipt of a remittance.

33 and 34 LUDGATE HILL, LONDON, E.C. ESTABLISHED 1749.

London, June 22nd, 1860.

Leeches Wholesale and for EXPORTATION.

GEORGE HERMANN'S LEECH DEPOT,

32 Wilderness lane, Salisbury square, Fleet street, London E.C.

BEST HAMBRO' SPECKLED, 14s. per 100.
BEST GREEN, ... 7s. ,,
SMALLER GREEN, ... 5s. ,,

G. H. don't keep the smallest sizes (best known as Leeches for Hospital use).

The SAME (if desired) sent Carriage Free to all parts of the United Kingdom, 1s. 6d. more per 100.

Testimonials as to quality may be had.

Gazogenes.—Messrs MATHIEU, FRIQUET, and CO.

beg to inform Chemists, Druggists, and all concerned, that from the 15th of July next they will be the SOLE AGENTS for the celebrated BRIET'S PATENT GAZOGENE, or Soda-Water Apparatus; and that they will be ready to execute orders from the above date on the most reasonable terms.—Address, MATHIEU, FRIQUET, and CO., 5A Little James street, Bedford row, London, W.C.

Notice.—To induce a trial of SOUTH AFRICAN WINES,

at 20s. and 24s. per doz., bottles included, the consumption of which has now reached 420,000 doz. per annum ("Vide Board of Trade Returns"), a Case containing four samples, sealed and labelled, will be forwarded on receipt of THIRTY POSTAGE STAMPS, viz.,

Half-pint bottle of best South African Sherry.
Half-pint bottle of best South African Port.
Half-pint bottle of best South African Madeira.
Half-pint bottle of best South African Amontillado.
COLONIAL BRANDY, very superior, 15s. per gallon.
BEST GIN, full strength, 11s. 3d. per gallon.

Price lists free on application.

Address—Mr ANTHONY BROUGH, Wine and Spirit Importer, 29 Strand, London, W.C.

S. Bowles (late Windsor and Co.),

PHIAL and BOTTLE MERCHANT, Dealer in Druggists' Sundries, &c., 6 James street, Covent garden, W.C. The cheapest house in London for every description of MEDICAL GLASS of the best quality.

Samples and prices forwarded free on application.

REDUCTION OF THE DUTY.

WINES AND SPIRITS OF ALL SHIPPERS.

Her Majesty's Wine MERCHANT

— (ESTABLISHED 1811) — JAMES MARKWELL, — CELLARS, 35 to 40, and 45 Albemarle, and 4 and 5 Stafford streets, London; and of Bordeaux, Hockheim, Oporto, Xeres, and Pesth. Ports, from 30s.; Sherries, 28s.; Madeiras, 42s.; Moselles and Hocks, 40s.; Sparkling Hocks and Moselles, 48s.; ditto St Péray, 54s.; ditto Burgundy, 60s.: Clarets, 23s. Chablis, 30s.; Côte Rotie, 48s.; Champagne, 44s.; Sauterne, 40s.; ditto Yquem, 80s.; Essence of Turtle Punch, 56s.; Old Tom, 11s. 6d. All kinds of Foreign Spirits and Liqueurs. Particulars and direct Shipments of Montilla, Vino di Pasto, Amontillado, Oloroso, Xeres-Viejo and Manzanilla.—J. M. is AGENT for the celebrated American Bitters (Stoughton and Sickle's). Longworth's Sparkling and Dry Catawba; Monongahela and Bourbon Whisky; Schappes; Peach Brandy; Gin-Slings; Brandy Cocktails, &c, &c.—J. M. is always ready to give full value for Old Bottled Wines, to any amount. — Stock, 16,000 dozen. — Cash or reference. Bankers: Sir CLAUDE SCOTT, Bart.

Wines Reduced.—

EXCELLENT DINNER CLARET, 24s. and 30s.
SHERRY, PALE or GOLD, 24s. and 30s.
CHABLIS, first quality, 36s.
STILL HOCK and MOSELLE, 36s., 42s.
SAUTERNE, 42s.; BURGUNDY, 36s., 42s.
SPARKLING CHAMPAGNE, 42s.; SPARKLING HOCK and MOSELLE, 42s.
OLD BOTTLED PORT, 42s., 48s. per dozen.

Carriage paid by rail. Price Lists on application.

MARSHALL AND SON,

IMPORTERS OF FOREIGN WINES, PURVEYORS TO THE QUEEN,

20 STRAND, LONDON,—W.C.

Reduction of Duty.—

HEDGES and BUTLER having reduced the Prices of their Wines in accordance with the new Tariff, are now selling capital Dinner Sherry, 24s., 30s., and 36s. per dozen; high-class Pale, Golden, and Brown Sherry, 42s., 48s., 54s. Good Port, 30s. and 36s.; fine old Port, 42s., 48s., 54s., and 60s. Pure St Julien Claret, 24s. and 30s.; very superior ditto, 36s. La Rose, 36s., 42s. Finest-growth Clarets, 60s., 72s., 84s. Chablis, 36s., 48s. Red and White Burgundy, 36s., 48s. to 84s. Champagne, 42s., 54s., 60s., 72s. Hock and Moselle, 36s., 48s., 60s., to 120s. East India Madeira, Imperial Tokay, Vermuth, Frontignac, Constantia, and every other description of Wine. Fine old Pale Cognac Brandy, 60s. and 72s. per dozen. Schiedam Hollands, Maraschino, Curaçao, Cherry Brandy, &c. On receipt of a post-office order or reference, any quantity, with a Priced List of all other Wines, will be forwarded immediately by HEDGES and BUTLER, 155 Regent street, London, W., and 30 King's road, Brighton.

Originally established A.D. 1667.

Wood and Watson's South African Port, Sherry, &c., 20s. per dozen.

Pint Samples or 12 stamps each. Excellent Brandy, 16s. per gallon.

Pale India Ale and Stout, 4s. 6d. per dozen quarts, 2s. 9d. per dozen pints. Scotch Ale, 5s. 6d. per dozen quarts, 2s. 9d. per dozen pints.

Address, 16 Clement's lane, City, E.C.

Kinahan's LL Whisky v. COGNAC BRANDY.

This celebrated old IRISH WHISKY rivals the finest French brandy. It is pure, mild, mellow, delicious, and very wholesome. Sold in bottles, 3s. 6d. each, at most of the respectable retail houses in London; by the appointed agents in the principal towns in England; or, wholesale, at 8, Great Windmill street, Haymarket.—Observe the red seal, pink label, and cork branded "Kinahan's LL Whisky."

CLINICAL LECTURES.

ON FRACTURES IN CHILDREN.

By M. GUERSANT.

DELIVERED AT THE HÔPITAL DES ENFANTS.

M. Guersant has devoted several of his recent lectures to a practical consideration of fractures in children, and the *résumé* here presented contains the results of a lengthened special practice in and acquaintance with their surgical pathology.

Fractures in children present, especially in their diagnosis, treatment, and progress towards a cure, peculiarities and shades of difference with which the surgeon should be well acquainted. Before entering on questions of a purely practical nature, I shall say a few words on the frequency and the etiology of fractures occurring in the different periods of life.

From long practical observation, we have learned that children become the subjects of fractures as often as adults or old people—a fact about which you may easily satisfy yourselves by walking through the wards of this hospital. A comparative study of the predisposing causes of fractures will easily account for this equality of frequency. Thus, as regards the texture of the bones, we find an important analogy existing between the two extreme periods of life. In childhood, as in age, the medullary canal of the long bones is larger, and the walls of the diaphyses thinner; but whilst the osseous tissue in old persons is hard and fragile, in children the same tissue is soft and flexible. In the latter, the physical properties of the bones might be supposed to render them more capable of resisting the causes that produce fractures; which is not really so—for experience shows that the bones of infants, notwithstanding their elasticity, cannot be bent to any extent without being broken. In adults, the bones, wanting the same anatomical predispositions, owe their relative frequency of fractures to the relative multiplicity of the occasional causes to which they are exposed. Another predisposing cause, common to children and old people, is to be seen in the state of the muscular masses. The muscles in both are, in fact, feeble, and both are consequently more exposed to falls, and, for that reason, to fractures. Let us remark, however, that falls do not so often occasion fractures in children and old persons as in adults; a difference evidently owing to this—that the former fall down as it were in a lump, without making any great effort to save themselves, while the aged experience in their very efforts a new predisposing cause of fractures.

As predisposing causes, the imprudence and rashness of children can only be equalled by the irreflection and bravados of old people. If the former pass before cars and carriages, climb trees, and get on the roofs of houses, without thinking of the danger they incur; the latter, forgetting that their pace has become slower with age, traverse the streets in the midst of carriages, or venture alone on roads that are difficult or dangerous; and hence both become victims to the accidents under consideration. It is thus that most of the accidents that occur in the street happen to children and old people. In children, among the special predisposing causes we may indicate rachitism, which, as we shall see, sometimes has an influence on reunion. If we look next at the determining causes, we shall again have the long list of every sort of external violence which authors assign as the causes of the same accidents in adults. As regards their situation, these fractures present some peculiarities. Thus in children it is the middle part of the bones of the extremities where the solution of continuity occurs almost constantly. It is interesting to observe that, in early years, fractures of the forearm occur most frequently in the middle part, and, contrary to what takes place in adults, you rarely see in children fracture of the lower extremity of the radius. This inverse difference arises from the different ways that children and adults have in opposing external violence. When the latter fall, they throw out an arm in order as much as possible to save themselves; but the former make no sort of resistance, but fall just as any mass would, and with their arms between their bodies and the ground. This difference of instinctive action explains why the wrists are so generally the seat of fractures in adults, and the long bones of the superior extremities in children.

If we next turn to the pathological anatomy, it will be seen that in children the same varieties occur as in adults—fractures more or less transversal, and fractures oblique, and even longitudinal. There is, however, a variety of fracture recently described, that I have not yet encountered in children—I mean the fracture *en coin*. Observe that I do not deny the existence of such fracture, but I believe it is less frequent than in adults—a circumstance I would also point out to your notice.

A variety to which I desire particularly to draw your attention, since it is in some measure peculiar to infancy, is the incomplete fracture, or fracture in which the fragments preserve with each other a certain degree of continuity. As incomplete fractures I consider two states that differ widely in an anatomo-pathological view. In the one, the bony substance is completely broken; but the periosteum, which remains entire, prevents any degree of displacement. In the other, the osseous matter and the poriosteum together resist effectually the traumatic force. You already see all the importance of this fact. The frequency of incomplete fractures in children explains the rareness of displacement and riding of the fractured ends—a circumstance highly favourable to the rapid and even consolidation which we are accustomed to see in the fractures of children. From this fact also is derived the precept of examining with much caution the fractured bones, in order not to aggravate the evil by disuniting parts that are still in their place, with a view to cause crepitation, which it is sometimes difficult, if not impossible, to produce.

Fractures present in children the same complications as in adults; but as the latter are, on account of their occupations, more exposed to graver causes of traumatic violence, so in them complications are more frequent and of a character more serious than in children and old persons. You can imagine, too, that children, being under the eye of their parents, and the aged, being no longer engaged in dangerous occupations, escape usually the frightful mutilations that so often accompany complicated fractures in adults. In the children which we have seen mutilated by wheels in factories or crushed in the street, the complications, other things being equal, have been attended with less danger than the same accidents at any other period of life.

Clinical examination shows that, in the youthful subjects under consideration, fractures of any bone of the skeleton may be produced. You thus see them in the long bones, as well as in the short and broad bones, (just as in adults and in the aged,) and in every situation, excepting the neck of the femur; though this bone I have seen dissevered from its epiphysis—a circumstance essentially different from what takes place in the aged.

As regards the symptoms, it may be said, generally, that the same functional disturbances correspond to the same lesions in children as in other subjects. Yet it is well to add that, whether it be owing to the comparative shortness of the limbs, or to the rareness of displacement, fractures in the former show less to the eye than in adults—a fact owing either to the more limited extent of the members, or to the infrequency of displacement. Hence it is reasonable to look for the fracture in the situation where the greatest pain is felt. It is unnecessary to add, that where there is striking deformity, the significancy of this is the same in all subjects, with this trifling distinction, that in children the reduction is easier. Children usually cry the moment you touch them—some of them even outrageously—and then nothing can be gathered from the effects of pressure in augmenting the pain.

I cannot too strongly inculcate a cautious reserve while making your manual examinations; for, independently of the fatigue which you may occasion the little patient, you run the risk of breaking completely parts that are but imperfectly disunited, and so of changing an incomplete into a complete fracture. It is sometimes difficult to ascertain the existence of fracture in such young subjects; for their resistance on the one hand, and the small dimensions of the limb on the other, added frequently to the firm and elastic state of the cellular tissue covering the injured parts, are so many hindrances to a perfect examination. But in doubtful cases especially, where the pain is acute, I do not try to arrive at certainty, seeing it can serve no purpose. I think it better to be deceived, and apply an apparatus to a limb where there is only a simple contusion, than to complicate a fracture by imprudent tentatives that could but satisfy my curiosity at my patient's expense. Besides, in children consolidation is so rapid that there can be no great inconvenience in treating such accidents as you treat fractures, the requisite time being so short. I would even say, that were the case one of mere contusion, the state of immobility would be an excellent curative means, by hindering the painful concussions and movements which children know not how to avoid.

Now where fracture really exists, what is the prognosis? I do not hesitate to say that non-complicated fracture is, in children, a simple and unimportant accident. You may, therefore, in every case, reassure the patients by saying that fractures at that age are in no respects to be compared with the same lesions in adults and old people. The medium time for consolidation is from eighteen to twenty days; but of this we shall speak again when we come to mention the proper period for the entire removal of the apparatus.

I must further direct your attention to the manner in which consolidation takes place in young subjects. The bones usually re-unite with perfect regularity and without any visible shortening; and where the treatment has been properly directed, no trace even of deformity is perceptible, in such cases at least as are free from serious complications, for these may greatly modify the progress of the lesion.

I am every year visited by conscripts, who come at the time of conscription for certificates; and often I cannot ascertain that a fracture has ever existed but by the house-registers; and my opinion is so much that of the Council of Revision, that these young men are always considered fit for service.

I have said that consolidation takes place without apparent shortening; but there almost always exists a slight diminution of the length of the fractured limb, as may be ascertained by very careful measurement. Yet such individuals do not halt in their gait, but accustom themselves when walking to a compensating degree of deviation in the pelvis.

You may see at this moment, in the Salle St Pauline, a girl of four years, who, in 1858, was twenty-five days in the same salle for a fracture of the thigh. It is impossible now to discover the slightest trace of the accident. When the patients are somewhat older, they walk lame for the first months; but their lameness soon disappears entirely, although there is generally a real but slight shortening of the limb.

FRACTURE OF THE THIGH.

By J. B. NICOLSON, M.D., M.R.C.S., L.S.A.

The sciences of Medicine and Surgery even within a very recent period have still continued, both in theory and in practice, to make great and solid progress, notwithstanding the brilliant discoveries made in former days—a progress corresponding even to that made in the other sciences. The consequence is, that *most* of the cases occurring in the present day, whether they be Medical or Surgical, rarely present the slightest degree either of novelty or of originality. However, the following surgical case may possess some details worthy of notice, inasmuch as it shows, in the treatment even of the *severest* cases of fracture of the thigh, the great superiority of the "straight position," as effected by Desault's long splint, over any other, especially in the periods of youth and of middle age.

A boy of the name of Sanders, fourteen years of age, of a healthy constitution, sustained in the month of April, 1859, a fracture of the right femur, caused by the broad wheel of a heavy waggon having passed over it. The accident occurred in this way:—He was driving a heavy-loaded waggon, and, while walking before it, by an accidental slip of the foot he fell to the ground, and, before he could recover himself, the wheel passed over the thigh. The site of the fracture was about the junction of the superior and the middle thirds of the femur; and, though neither compound nor comminuted, the bone was broken in two places, within two inches of each other, the fissures being oblique, not transverse. Owing to the great breadth and weight of the wheel, the soft parts were much contused, considerable injury having been done apparently to the vascular, nervous, and muscular tissues; consequently great swelling, pain, increase of heat, and lividity of the surface, from the extravasation of blood into the soft parts at the seat of injury, soon followed in the affected part. From the powerful action of the "adductor muscles," the lower fragments of the bone were drawn upwards and behind the upper fragment, causing great shortening of the limb, to the extent of nearly two inches, with inversion of the foot; the iliacus internus and the psoas magnus muscles no doubt also assisting in producing the shortening and the deformity.

Strong and steady extension and counter-extension of the limb, continued for some length of time, were had recourse to. A bandage was first rolled round the foot, ankle, leg, and thigh; Desault's long splint, of an appropriate size and length, extending from a little below the armpit to four or rather five inches beyond the foot, and suitably padded, was applied to the outside of the limb, the perineal bandage, with a pad placed in the perineum, not being omitted. With a view to ensure with the utmost certainty the complete rest of the fragments of the bone, it was thought advisable to apply also another smaller splint, padded, to the inner surface of the thigh, extending to a little below the knee, the whole having then been retained by suitable bandaging. A few turns of a bandage were finally wound round the waist and body, so as to approximate to the side the upper portion of the long splint.

In consequence of the great contusion of all the soft parts, it was necessary to bandage so that easy access might always be had to the seat of the fracture, for the purpose of applying warm fomentations of camomile flowers, &c., with at first an occasional poultice, until the swelling and increased heat had abated. For the first two weeks considerable constitutional disturbance supervened, which was treated with saline mixtures and effervescing draughts; an opiate at night being sometimes required, and strict attention being also paid to the condition of the stomach and bowels. At the end of eight weeks the splints were removed, and he was permitted to leave his bed, and to move about by the aid of crutches, with the foot of the injured extremity supported by a sling round the neck. By-and-by for these was substituted merely a stick, and at the end of three months he was able to walk about without any support.

Owing to the fragments of the bone having been brought into complete apposition and kept so, there was not the slightest shortening of the limb nor the least deformity perceptible, the sole result of the accident at my last examination being a little thickening of the circumference of the femur at the site of the fractures from the previous deposition of callus; and even this result would in the course of time by the process of absorption be gradually lessened, and most probably would ultimately disappear altogether.

As this was a most severe accident, attended with serious injury to the vascular, nervous, and muscular tissues, complicated also with great shortening and deformity, and as a perfect cure was effected by the use of certain means, without either shortening, or deformity, or ultimate weakness of the limb in the slightest degree resulting therefrom, the case has been considered deserving of being recorded. Practical results are the only true and safe criterions whereby we can satisfactorily judge of the superiority of one mode of treatment over that of others.

Robertsbridge, Sussex, July 14, 1860.

THE SPIRIT OF THE PERIODICALS.

We extract the following report of a discussion on *Osteo-Myelitis consequent on Fractures in Gun-shot Wounds*, from the 'Journal of Practical Medicine and Surgery:'

"An important question of surgery, and more especially of military surgery, was raised before the Academy of Medicine by one of its most active and learned correspondents, M. Jules Roux, Head Naval Surgeon at Toulon. Our readers are already aware from the minutes of previous meetings that we allude to the still mooted point of the most eligible part for secondary amputation and for disarticulation, substituted for amputation in the continuity of the limb, to avert the incessant danger of *osteo-myelitis*. Osteo-myelitis is, in M. Jules Roux's estimation, the cause of the commonly fatal issue of secondary amputation performed in the continuity of the shaft. Compelled to resort to a further mutilation, after protracted suppuration, the surgeon has not unfrequently rendered but an unprofitable service to the patient: the bone, still diseased, where the saw has for the second time divided it, does not cease to suppurate, and few subjects can withstand this persevering drain upon their constitution—an inevitable consequence, according to M. Roux, of inflammation, when, from the fractured point, it has reached the medullary membrane and the texture of the entire bone. Hence the precept to amputate to the joint, in obedience to the principle universally accepted in surgery, that an operation, to be rational, must remove the whole of the evil.

"We have recorded the astonishing success which has given authority to M. Jules Roux's theory. Of eight soldiers, consecutively amputated in the continuity of the limb, two only survived. M. J. Roux, on examination of the bones, observed that they were totally invaded by the inflammation, which he denominates *osteo-myelitis*, and he accordingly at once modified his practice: twenty-two patients, who had reached the advanced stage, which he calls *period of osteo-myelitis*, were amputated in the joints, and M. Roux numbered twenty-two cures, four of which were disarticulations of the hip, and thirteen of the shoulder-joint. Assuredly, were these magnificent results alone considered, and were they susceptible of no other plausible explanation than the theory of osteo-myelitis, all surgeons should hasten to adopt M. Roux's ideas; but such does not appear to be the case. The too few speakers who who took part in the discussion raised by our learned fellow-practitioner of Toulon, Messrs Larrey, Robert, Jobert de Lamballe, and M. Legouest, in a letter addressed to the Academy, stated in reply that osteo-myelitis is not so constant as M. Roux imagines; that it is often susceptible of spontaneous cure; that clinically and anatomically it is difficult to discriminate between the first and second degrees, the benign from the grave variety of the inflammation; that surgeons, when amputating in the continuity of the limb, have often found in the medulla and the bone the anatomical characters of serious osteo-myelitis, and yet have saved some of the patients; and finally, that suppuration of the medullary canal itself is not necessarily fatal.

"Such are the objections urged against M. Roux's doctrines; but as it was, however, desirable to account for the success of the eminent surgeon, it was ascribed to the occult influences of medium, season, constitution, *i. e.* the contingencies of chance. This, as M. Jules Guérin correctly observed in the 'Gazette Médicale,' was but imperfect justice to the sagacity and surgical skill of the operator: 'That M. Roux is mistaken in attributing to his principle the excellence of his results may be possible; but why deprive him of the benefit of his unfailing practical instincts, and of the advantages of his great surgical experience? Traditional practice teaches that there are opportunities to be chosen, circumstances to be preferred, precautions to be taken, dangers to be avoided, remedies to be employed; M. Roux is doubtless indebted to his thorough knowledge of these particulars for his constant success.' M. Guérin's opinion was, if we err not, shared by the majority of his colleagues of the Academy. Yet, acknowledging with our eminent fellow-practitioner that M. Roux's sound sense, exquisite tact, and knowledge have considerably contributed to the results he has achieved, one element more must perforce be introduced into their interpretation. Otherwise how are we to account for the disastrous consequences which the same sound sense, the same exquisite tact, the same knowledge were unable to avert in the wounded who underwent partial amputation of the limbs? There is obviously a something beyond the product of these high qualities which distinguish M. J. Roux, and that can scarcely be a mere caprice of chance. Caprice is, from its very nature, trancient; and when it appears to last too long and to recur too often, some unnoticed truth, some disregarded principle lurks beneath the fortunate or unfortunate series of facts, a truth or principle which should be brought to light by dint of patience and perspicacity. In a question involving interests of so momentous a nature, the impatient public observed with painful surprise the silence of Messrs Velpeau, Cloquet, Laugier, Malgaigne, Denonvilliers, Nélaton, Huguier. Was their silence merely the expression of doubt and the sign of philosophical abstinence? We must presume it was, but M. Roux's paper seemed to deserve a more encouraging reception. All possible objections and abstentions united cannot prevail against the significant fact that, in the case specified by the surgeon of Toulon, eight amputations in the continuity of the shaft resulted in death, and success attended the entire number of his twenty-two disarticulations."

The 'British American Journal' contains the following case of *Mechanical Obstruction of th Intestines, and Gastrotomy*, ending in death, by Dr P. O. TESSLER:

"Mrs C. G., a young woman of good constitution, took sick on the 8th of last month. I was sent for in the afternoon, and I found her with a slight fever, a hot but not very dry skin, a quick pulse, headache, a glossy and slightly furred tongue, with an irritable stomach, and colicky pains around the navel; her bowels had been moved the previous evening. She blamed getting her feet wet for all this difficulty. I prescribed chloride of mercury and compound ipecacuanha powder for the evening, to be followed by some evacuant medicine in the morning.

"On the 9th, she was a great deal worse; her stomach, more irritable, had rejected the medicine, and her bowels had not been moved. Sixteen ounces of blood were abstracted from the arm, a prescription of chloride of mercury and opium was ordered, and low diet enjoined.

"On the 10th and the 11th, the patient was a good deal better, but her bowels had not been moved. I ordered castor oil, which the stomach rejected.

"On the 12th, purgative doses of chloride of mercury were administered with olive oil enemata, but all to no purpose; she threw up the contents of the stomach and had no passage through her bowels, though her urine was free all the time. The train of symptoms observed at the onset of the malady returned with increased violence. After having ascertained that the abdominal and pelvic apertures were all right, and having made a close examination of the rectum and vagina, I began to suspect the pre-

sence of an internal mechanical obstruction, although the symptoms were not well defined. I was advised to try frequent fractional doses of sulphate of magnesia, with turpentine clysters, fomentations over the abdomen, and general hot baths, all which was strictly carried out.

"On the 13th, she threw up some stercoraceous matter and presented an aggravation of all the symptoms previously noticed, but as yet there was no evidence of the precise locality of the internal mischief. Dr Lemieux had been called in by the family, and I suggested the names of Drs Blanchet and Bardy, jr., who were immediately sent for. We agreed to resume the purgative doses of chloride of mercury, the enemata, and the baths.

"On the 14th, the distress of the patient was greater; and as I felt something like a tumour on the left side of, and a little below the navel, I came to the conclusion that I had to deal with a volvulus of the flexure of the colon, causing a mechanical obstruction irremoveable by any but operative interference. My professional brethren confirmed my judgment, and I and they apprized the patient and her friends of the precarious state she was in, and told her what a small chance of life an operation would leave her. She wasted six valuable hours in deciding upon submitting to the operation. At first her vital depression was not very great.

"When her mind was made up, she was placed on a table, in a good position, and in a room properly heated. As soon as she was fully under the influence of chloroform, I placed myself between her knees and made an incision in the mesial line, from the umbilicus to about an inch of the pubis, through the cellular tissue, the sheet of the left rectus,—the relation of parts having been deranged by the intumescence,—and then through the aponeurosis of the oblique muscles, when I reached the peritoneum, which I divided on a director with a probe-pointed bistoury; a gush of serum ensued, followed by coils of thickened, distended, and discoloured intestine, curling over the wound, so much so as seriously to interfere with a proper examination. I then extended my incision to about two inches and a half above the umbilicus, whilst the intestines were supported by my assistants.

"I immediately searched for the flexure of the colon, which I found readily, but so convoluted that I could hardly recognise the direction of the twist. Whilst examining it, a softened patch above the constriction gave way, which allowed the contents of the intestines to flow out; but a ligature was immediately placed on the aperture, which was about a quarter of an inch large. I then divided an adventitious band crossing the convolution, and the obstruction was at once relieved, when another patch gave way at the twist, which allowed the contents of the intestines to flow out, a small quantity of which fell into the abdominal cavity. This was sponged out as carefully as possible, a ligature was applied to the rupture, and the intestines were replaced. The wound was closed and dressed with twisted sutures and long strips of plaster across the abdomen, the whole supported by a broad bandage round the body. After the operation was over, the patient was put to bed, quite exhausted. She was given stimulants, which rallied her for a while, but she sank again and died about two hours after the operation.

"The case was not very satisfactory in its results; but I had a duty to perform, and the moment I could satisfy myself as to the nature and the seat of the obstruction I operated, and I do not regret having done so. Under similar circumstances, I have no hesitation in saying I would act in the same manner.

"The only thing I regret is the length of time the patient took to decide on submitting to the operation."

The 'London Medical Review' is a new candidate for popularity. Its first number does not contain any papers of particular interest, most of them being on subjects already worked out in the other journals. The following observations, however, on a philosophical arrangement of *Tumours and New Growths*, by Dr Wilks, deserve attention:

"The leading idea which pervades the writings of Surgeons and Pathologists with respect to new growths is that they consist of two kinds, the malignant and innocent; the former corresponding to cancer, or to a mass of nucleated cells, according to the microscopists, or to an heterologous formation, if we adopt the expression of Carswell; the latter being the opposite of all these. This great division of tumours into malignant and benignant is no doubt a natural one, and to understand the distinction and have a thorough knowledge to which class any given example belongs, is of the utmost importance to the Surgeon as well as the unfortunate subject of it. Moreover, this division involves in its consideration the whole pathology of the subject of tumours, including the question of the respective influences of constitutional and local causes in their production, as well as their physical and microscopic characters.

"What is meant by a new growth? We make use of the term growth to express that constant reproduction of the tissues which we suppose is always in progress throughout the body; that as the various structures are in a state of perpetual decay, so are they as constantly being renewed, either from a plasma supplied by their blood-vessels, or by some more subtle method of growth from their own elements. This process, of whatever kind it may be, is *physiological;* now if we suppose this plasma or exudation from any part should occur in excess, a *pathological* process is in operation and a tumour is the result. The difference between the two cases is this, that in the first every structure produces its like, whereas in the latter the affinity is in great measure lost between the exudative material and the tissue whence it springs, and consequently development is impossible except into structures of the simplest kind. For example, we find that no exudation from the viscera, as from brain, liver, lung, or from a tissue, as the muscle, can produce a tumour resembling in the slightest degree the original organ whence it has its origin, but one which consists only of the simplest elements, viz., cells or fibres in various combinations and degrees of development. And thus it is that the great majority of tumours are composed of nothing else than these constituents. If, however, the structure from which the exudation takes place be of a simple kind, or not of that complex organization seen in the viscera, a developmental process may occur in it, and thus it is that a tumour growing from bone may become osseous, or (since cartilage precedes bone in growth) enchondromatous; or, if arising in the medullary structure, myeloid. For the same reason, if the growth be near the female breast an adenocele is produced; if in the uterus or prostate, a muscular tumour; if in the skin, an epithelial or sebaceous one: again, should pigment be present in any part this may be reproduced, as in melanosis.

"We should inquire in the next place, what are the causes in operation which produce the exudation which we style pathological, and which results in a tumour or new growth? The general answer to such a question is in accordance with the idea already alluded to, respecting the malignancy and benignancy of all tumours, that in one case a constitutional, and in the other a local cause is in operation for their production. This is no doubt in great measure correct, for we cannot but distinguish between a tumour arising, for example, from an injury in a healthy person, and the case of manifold growths existing in a patient whose ancestors were the subject of the same disease. It will also necessarily follow from what was just now said, that owing to the modifying influences of the various parts of the body upon the new growths, every feature of the latter which resembles the part from which it springs is due to a local cause, and as far as that local element is concerned the tumour is innocent. If this be not admitted, it must necessarily follow that the same structures as bone are at one time malignant and at another time innocent, as in the case of osteoid cancer and exostosis. Also in the case of those more complex structures which cannot produce tumours resembling themselves, we must take, as evidence of the innocency of the latter, the attempt at production of a tissue of the highest possible grade which the circumstances will allow. We will start then from this proposition, that the fact of the production, in any new growth of elements similar to the healthy part whence it springs, exhibits a healthy influence in operation; and if from the complexity of the original organ the formation of a growth resembling it be not possible, then that the highest grade of tumour under the circumstances be taken as evidence of the same fact. On the contrary, all morbid products which have no developmental power, but consist simply of cells, show a want of healthy influence, whether these cells arise in a complex organism or in a simpler structure. Such are generally styled cancer, and evidencing some fault or vice in the constitution, are also called malignant. It will be seen that this opinion tends to the belief that a cell growth exhibits a malignant, and a fibrous an innocent influence in operation, and that the production of one rather than the other depends on a constitutional cause. It would be too much to assert this dogmatically, seeing that the subject is beset with many difficulties, but we shall see, as we advance, to what extent we think local causes alone may influence the character of tumours.

"Suppose, then, that from some cause an exudation should occur from a soft organ, or from the surface of the body, and that this blastema or plasma should produce nothing but a mass of cells or nuclei which show no tendency to develop either into tissue or any higher formation, and that these are constantly increasing in number; we see in this a state of things which is so far removed from every healthy action that no other term can be adopted towards it than one expressive of a highly morbid state, and one to which the term malignant is especially applicable. In this production of cells, which may be called objectless or having no purpose in the healthy economy, we perceive the very essence of malignancy; for if we consider on the one hand that the fluids of a part are employed in its nutrition or constant regrowth, such a departure from the process as is exemplified in the production of a mass of cells, similar to those which constitute the foundation of the tissues in the embryonic state, must necessarily evince a highly morbid state. In calling these cells embryonic, we do so advisedly, for from a long study of the subject we are unable to ascertain in what respects they differ from those elements which constitute the basis of the healthy tissues. A very prevalent opinion we know exists that cancer-cells are heterologous, or of a kind altogether foreign to the system, and are to be distinguished as such by certain peculiarities from the cells just named. Indeed, there are eminent microscopists who maintain that cancer-cells are characteristic and always distinguishable. Without denying the capabilities of these observers, we may state our own incapacity to recognise these peculiarities, and moreover, from the writings of these microscopists, we cannot discover what are the distinguishing characters by which they describe them. We agree, indeed, with these pathologists, that a cancer-cell is one which generally contains a large oval nucleus with a distinct nucleolus, and that a new growth composed of a mass of such cells should be regarded as malignant; but, if unacquainted with the source of the tumour, we should hesitate in pronouncing a verdict of malignancy upon any given cell. Moreover, all must admit, in the most virulent forms of cancer, it often happens that no cells of any kind are present.

"We repeat then, for the sake of exactness, our belief that a cancer consists merely of a mass of embryonic cells; that owing to a morbid influence being in operation at the site of the disease, the ordinary nutrient fluids, instead of being employed for the healthy maintenance of the part, produce these nuclei or cells, which showing no tendency to develop into a higher formation, but having an utterly purposeless object, evince by this very fact the existence of a disease to which no other term but that expressive of malignancy can be applied. It would follow from this that the mere existence of a mass of cells constitutes a malignant disease; and on the other hand, should these cells show any disposition to develop into fibre, so far is that an evidence of a corresponding healthy or innocent influence in operation. Such a view will bear the test of clinical observation, and therefore, that just in proportion as we find in any given tumour presented to us for examination, a crude formation of cells and nuclei, or a tendency to the formation of fibre, so can we pronounce upon its degree of malignancy or innocency. In the more marked forms of cancer we think the naked eye appearance, as shown especially by the presence of milky juice, is as characteristic as the microscopic.

"Now, since it is generally considered that a nucleus exists before a cell-wall, we may regard the latter as evidencing, when present, a higher

state of development than the former, and consequently affording a proof of the existence of a more healthful influence in operation than where the nucleus alone is present (always understanding the term development as identical with the disposition to progressive organization). Therefore, it is in the acutest form of cancer, as the *encephaloid*, that we often fail to discover any cells, the great mass of the tumour being composed of nuclei inclosed in a delicate homogeneous matrix; these, with the bloodvessels, being the only constituents of this form of cancer. It is worthy of remark, therefore, that the worst kinds of cancer are those in which we fail to find the cells which are supposed to be characteristic of it, and thus we can understand the disappointment of learners, who generally choose such well-marked examples of the disease for microscopic examination.

"Should, however, the material which intervenes between the nuclei form a good cell-wall, then we may regard the growth as having a disposition to develop, and consequently it has one degree less of a morbid character than that consisting merely of nuclei. Thus we find the well-marked nucleated cells in tumours of slower growth, and in those less disposed to spread; and further, should the cells tend to develop still more, and become pointed or angular, so much the more would they show a certain amount of healthy influence in operation. It is in *scirrhus* that we often find such cells, and it is from the fact that it was the class of tumours bearing this name which were mostly examined by our early microscopists, that a very general opinion prevailed that cells having this form were characteristic of cancer. The fact also of the matrix which holds these cells together being composed of a tough fibre tissue is another evidence of the disposition to development, and this is quite in accordance with the observation that scirrhus is a much less virulent form of cancer than the encephaloid.

"Let us now suppose that in the exudation from a part, the cells should have a still greater disposition to grow, and distinct fibres should be formed, the tumour so constituted is of a less malignant character than that consisting merely of cells or nuclei Such a growth is called *recurrent or malignant fibroid;* it may return many times after removal, and in the course of years may even propagate itself internally, as in the lungs. It may be designated *semi-malignant*, as holding an intermediate place between cancer and a simple fibrous tumour. It was a tumour of this kind which puzzled the older microscopists, who, impressed with the notion that all growths were either malignant or innocent, did not understand the character of one which did not consist of cells, but yet returned after removal. An unprejudiced conclusion, however, expressive of a hesitation between the extreme views of malignancy and innocency, would have been correct. The outward appearance also of such a tumour exhibits the true position it should take; its softness and vascularity, its disposition to return on removal, and its occasional propagation internally, are properties sufficiently marked to claim for it the name of fungoid; while, on the other hand, its fibrous nature, its absence of milky juice, and its circumscribed form, would all point to its benignancy. If to these be added its slow growth and microscopic character, its true character is evident.

"In the third place, let us suppose that the exudation should change into a simple fibre; that the cells according to Schwann should slit up until a simple fibrous tissue be formed. We should then have a still further developed structure, and the highest, indeed, which seems possible in the complex organs; a *fibrous tumour* may therefore be called benignant, as it consists of the most innocent adventitious material which can be found in the body. The microscope shows it to consist of ordinary areolar tissue displaying the usual nuclei on addition of acetic acid.

"It will be seen that although we have spoken of innocent and malignant tumours, and of the recurrent fibroid holding an intermediate position, yet as between these there must necessarily be many other grades of development, so the tumours composed of each of these grades will have different degrees of malignancy. For instance, there is a tumour called gelatinous sarcoma or collonema, composed of delicate fibres springing from nuclei, and which sometimes returns after removal; also a tougher growth composed of nucleated fibre, having small oat-shaped nuclei, displaying a more innocent character. These we need not allude to, but regard the three main divisions of innocent, semi-malignant, and malignant, as typical, and sufficient to exemplify our present views. These intermediate varieties, however, deserve a careful practical study both clinically and microscopically, by which means we shall be enabled to discover by their anatomical structure what degree of malignancy attaches to each."

The 'Lancet' opens with a Clinical Lecture by Dr W. T. Gairdner of Edinburgh on the *Distinctions of Typhus and Enteric (Typhoid) Fever.* The Author agrees with Dr Jenner as to the non-identity of these forms of fever, and after a description of the enteric fever he observes:

"Have we, then, here before us *two distinct fevers with two distinct eruptions, or only one fever with two varieties of eruption?*—that is the question. Let us look at it, first, in the light of the six cases at present in the ward.

"Two of these cases, I have already told you, were recognised, not by a careful investigation of symptoms, but simply by a single glance at the eruption, as cases of typhus. What is the history of these cases? They are two sisters of a family of five—namely, a mother, three daughters, and a son,—who, with a lodger, occupied a house in in St Mary's wynd, in the immediate neighbourhood of a large tan-work. Of these six persons, five have had fever; and we know positively that in all of these it has been typhus with eruption. The brother and the lodger you may see for yourselves in the male fever ward; the mother was the very last case of typhus we had under treatment in our own ward, and it is now more than a month since she died (May 1st). We do not know whence this fever originated; there is some ground for suspicion that the mother was visiting a fever case in another ward in the hospital before she was attacked, but as I cannot trace the story distinctly we had better not insist upon it. Be that as it may, we have here evidently a group of five cases having a common contagion; and all of them prove to be typhus with distinct typhus eruption. Excepting this group, there has not been a single case of typhus in the Infirmary, I believe, since the 25th of April, and then only one, from the New Town. In March, there was only one case—a girl from Dalkeith. In February, there was only one case—the last of a little group which, like the present group, was composed of typhus cases only. In January there were one or two other cases. In the Dispensary books I find no case of typhus recorded since March, except one of those which I have noticed as admitted here. So that for three months at least (we may say confidently) Edinburgh has been almost clear of typhus fever, with the exception of the cases now enumerated.

"As regards the four cases of enteric fever, I find that three of the four are apparently quite isolated cases. This is in accordance with what we know of this disease, which has much less tendency than typhus to run into groups of cases, and is, I believe, much less contagious; but in the fourth case we have got hold of a link in a chain or group of cases, and this time the locality is not in Edinburgh, but in Penicuick, a village at nine miles' distance. I can tell you nothing about these cases from my own experience; but, fortunately, they were seen by Dr Thin, of Penicuick, who sent in the girl *as a case of enteric fever*, and assures me that her brother had the same fever, with a like eruption, in a severe form; and that other cases of the disease occurred in the same house. And I know that Dr Thin's observation is most implicitly to be trusted upon this subject, because he was a most valued pupil of mine a few years since, and had ample opportunities of studying fever during his attendance in the Royal Infirmary. Nothing short of having seen these cases with my own eyes could give me more confidence than this in telling you that they actually were cases of unquestionable enteric fever. Now, besides the cases under observation at present, I find recorded in the books of the fever wards only one case of enteric fever in May, two in April, one in March, one in February, two in January—all, so far as known to me, isolated cases; and, further, I find the Dispensary books quite void of any reference to the disease.

"Here, then, is the kernel of my argument. Fever has not been epidemic in Edinburgh for six months at least; on the contrary, it seems probable that there have been hardly a dozen cases of typhus in all, and about as many of enteric fever, in the entire town during the whole of that period. But five cases are found in a single household, and these are all, without exception, cases of eruptive typhus. One case of enteric fever is sent from Penicuick, and forms part of a little epidemic or local visitation there, which, we are assured by Dr Thin, consists of enteric fever only, and not at all of typhus, as distinguished by eruption. The two diseases are, therefore, as distinct as they can possibly be. No case of typhus has given rise to anything but typhus; no case of enteric fever has given rise to, or been associated with, anything but enteric fever.

"Now this is only a small contribution to a kind of experience of which Dr Jenner has availed himself with great care and exactness in the much greater field of London. Here, again, therefore, I may refer you to his paper, already mentioned, for further details. But there is this advantage in a small field, that you can be much more sure of exhausting your facts. No one can pretend to have had access to all, or nearly all, the fever cases of London, during however short a period. But in Edinburgh, Dr Begbie and myself probably have seen, or have had the means of knowing about, very nearly all the fever cases; and, therefore, when I declare to you that within my experience for ten years past no instance has occurred of a decided origin of enteric fever in a group of enteric cases, I am entitled to say that I have obtained very strong evidence in corroboration of the view, that these two diseases are, in reality, different diseases, and not mere varieties of the same disease.

"Last summer I made a very careful survey of the whole fever-field of Edinburgh (if I may call it so) for several months together. It was not an epidemic season; but I gathered about thirty cases of typhus and twelve of enteric fever, and into the whole details of these I inquired with the greatest possible minuteness, visiting every one of the fever localities, except one or two in which I was quite sure the cases were isolated. The result was that in no case could I light upon a suspicion that typhus had given rise to anything but typhus, or enteric fever to anything but enteric fever. The details of this inquiry you will find in the 'Edinburgh Medical Journal' for September, 1859.

"We had, however, in the Infirmary a melancholy proof that although typhus cannot give rise to enteric fever, or enteric fever to typhus, it is possible for persons who have passed through enteric fever to take typhus very soon afterwards. Last summer we were unable to avoid, during a certain period, the association of the two diseases in the same ward in rather excessive amount. Now, mark what followed. No case of typhus was seized with enteric fever; but no less than four of the dozen cases of enteric fever were attacked within a few weeks with typhus, and I am sorry to say that a mother of a very interesting family of five (who all, except the father, passed through enteric fever) died of this secondary attack of typhus; but although one of them was excessively debilitated, we succeeded in saving both. Another young girl had the two diseases in succession, but in each case mildly.

"I beg you to notice very particularly these facts; for not only are they full of instruction as to the danger of associating typhus cases with enteric fever, or indeed with any other fever, in the same ward, but they form the most conclusive of all possible proofs that the two diseases are distinct diseases. Typhus fever is not subject to a relapse; and it is a curious and indisputable law with respect to it, that it almost never attacks again, at least within a period of years, those who have had it before. Yet here we have three members of one family, within a few weeks, seized with two distinct febrile attacks, with two distinct eruptions, the attacks being separated the one from the other by a perfectly distinct convalescence. To make these out to be mere varieties of typhus fever, would require the whole laws of that fever, as ascertained by innumerable observations here and elsewhere, to be set at nought in this particular instance."

Dr Braxton Hicks continues his papers on a *New Method of Version in Abnormal Labour*, which we have already described. Mr Weeden Cooke contributes to the same journal, *Observations on some Rare Accidents*. The special subject of this article is a case of, *Cut Throat* with division of the larynx and pharynx, ending in recovery. After some general remarks on the necessity of being very exact in determining, for medico-legal purposes, whether such injuries were self-inflicted or not, Mr Cooke remarks:

"From a careful review of the cases which have come under my notice at the Royal Free Hospital during the last fifteen years, I derive the conclusion, that in all instances of attempted suicide the wound inflicted has been either just beneath or above the os hyoides; and that in cases of attempted murder the injury has been much lower down in the throat, generally beneath the pomum Adami. The reason of this is very manifest. The suicidal act is one of much physical as well as mental excitement. The individual throws back his head with great resolve, and the knife is naturally carried across the throat as near to the chin as may be. This throwing back of the head is not obtained by the murderer, and he is obliged to carry out his purpose with the chin much overlapping the laryngeal region. These positions will also account for another distinguishing circumstance—viz., the division of the carotid artery or arteries by the murderer, and their escape from injury in the greater number of instances of attempted self-slaughter. In the former case, these arteries, running as they do close upon the side of the trachea, in the middle of the neck, are almost necessarily implicated in the incision; whilst in the latter case, where the wound is inflicted just above or below the os hyoides, the carotids have bifurcated and somewhat retired towards the angle of the lower jaw, and so escape injury. In the cases of attempted murder that I have seen, the wounds have been superficial, as well as in the middle of the neck. If they had penetrated the trachea, it is not likely that in this situation the carotids would have escaped. The superficial wounds in this region which result from self-infliction are generally the effects of drunken brawls, or of a pretence to suicide as a means of extortion or exciting sympathy. The maniacal suicide invariably acts with greater determination, and succeeds in dividing the larynx at least, if not the pharynx also. The division of both windpipe and gullet, without injury to the carotids, is, however, a rare circumstance, and it is on account of this rarity and its instructive features that I venture to record the following history of a case of this nature which has recently been under my care:—

"W. J——, aged twenty-one, a very well-made, rather stout young man, had a twelve-month ago an attack of fever accompanied with delirium, which lasted several days. On his recovery he married and entered into business. He was of an anxious disposition, and business matters excited him, but nothing particular occurred until a few days before his wife was confined, when he became extremely depressed, so much so as to excite the attention of the medical attendant of the family. He was carefully watched, and medicine administered; but he managed, nevertheless, on the night of April 2nd, to cut his throat with a carving-knife. Considerable hæmorrhage ensued, but was controlled by the medical men called in, and he was then carried to the Royal Free Hospital in a sinking state.

"No bleeding of any consequence took place after his admission. He was put to bed, and an opiate enema administered. Upon my arrival at the hospital, I found him very blanched, and the pulse scarcely perceptible. The wound extended from the right side of the larynx across the throat to within half an inch of the lower jaw on the left side. The incision took effect between the os hyoides and the thyroid cartilage—in fact, through the thyro-hyoidean membrane which connects these two bodies, about an inch above the pomum Adami. The lower attachment of the epiglottis by the thyro-epiglottic ligament to the thyroid cartilage was severed, and it therefore remained attached by its hyo-epiglottic ligament to the os hyoides above, so that the opening of the glottis was quite undefended in the efforts at deglutition until reunion was effected. Passing through the posterior wall of the larynx, the incision extended through the anterior wall and sides of the pharynx, so that the back of the pharynx lying upon the cervical vertebræ was fully exposed. The patient was quite tranquil and essayed to speak, but the separation of the larynx from the mouth of course prevented the utterance of the sounds which the lips and tongue endeavoured to express. I diminished the wound by two sutures on the left side, leaving the fore-part open for the escape of mucus, and the purulent discharge which was to be expected. The head was bent upon the chest by means of pillows, to keep the wound in apposition; and as he was very tractable and anxious to get well, I did not find it necessary to bandage the head to the chest—a most irritating and uncomfortable proceeding. A pint of strong beef-tea with an ounce of brandy was injected into the rectum every three hours. The room was kept warm, and, as a precaution, a male attendant sat constantly by his side.

"Except an irritating cough, which was due to the increased bronchial secretion, the patient progressed favourably and without change for the first three days. Then he began to sip small quantities of egg and port-wine, some of which passed into his stomach, but some also escaped by the wound. The enemas were assiduously continued. There was thirst, and a great longing for food by the mouth.

"On the sixth day no air passed out of or into the wound, and small quantities of egg and port-wine were swallowed without escape. The voice was still extremely feeble, and there was much purulent discharge, with an irritating cough, which was relieved by small doses of laudanum.

"On the eleventh day, the voice had recovered its natural power; he partook freely of beef-tea, port-wine, and beer by the mouth; and the external wound was beginning to unite at its extremities. A few days after this, he began to take meat—panada, fish, and light puddings. A tonic also was ordered, as he continued very weak and anæmic. In one month he was able to go home, the wound being healed, with the exception of a few exuberant granulations; and he soon afterwards went to the sea-side to recruit his strength. Owing to the cicatrisation of the wound, the head was somewhat bent upon the chest; but gradually the new tissue will, no doubt, be elongated, and the head will recover its erect position.

"Beyond the medico-legal value of this case, it has its surgical teachings. It will be observed that, contrary to the instructions of some authors, and certainly in opposition to the popular notions, the throat was not 'sewn up.' The two sutures that were put in had the effect of lessening the skin wound only; but even these were of no avail, for the healing there did not take place by the first intention, but by subsequent granulation. Had the wound been closed entirely by sutures, the purulent discharge would undoubtedly have passed into the larynx and killed the patient, as would also any particle of food that may have been taken before the wound in the pharynx was closed. Mr Liston relates the case of a girl, whose throat was sewn up according to the then custom, and who was only saved from suffocation by a timely release of the sutures. Although this eminently practical surgeon entered a fierce protest against the use of sutures in these cases, I believe that it has not been sufficiently attended to; and that, both in books and in actual practice, the contrary proceeding is still advised and carried out. It may be that in some instances the position of the head requisite to obtain union will not be so easily maintained as in the case above recorded. My experience, however, teaches me that the large loss of blood which necessarily ensues from the division of the superior thyroid and superior laryngeal arteries almost invariably subdues the most violent maniac, and that he submits himself calmly to all the means employed for his restoration. If there be restlessness, however, the patient may be made to wear a nightcap with a piece of elastic webbing attached to each side, this being carried down and fastened to a waist-belt or bandage. Lastly, the method of feeding the patient is a matter of such practical importance that his life may be said to depend upon the plan adopted. There are four means of administering food to a patient whose pharynx is opened, a tube being used in all. This instrument has been passed into the œsophagus through the wound, by the mouth, and up the nostril. The fourth mode of sustaining the patient until the division of the pharynx is healed is by injecting the rectum. The obvious advantage of the latter proceeding is, that the act of swallowing, which necessarily disturbs the parts, is avoided altogether; whilst it will readily be conceded that the irritation set up in the fauces by the presence of the instrument, even if used in the least objectionable manner—namely, by the nostril—must be sufficient to interfere very injuriously with the process of reparation. It would be scarcely possible to conceive any surgeon passing the tube in through the wound, were it not that instances of this proceeding are on record; and the consequence has been, that no union was effected until the edges of the parts were vivified by the knife and brought into contact by position. As after laryngotomy and tracheotomy the wound has upon rare occasions left a fistulous opening, so is it recorded that the same circumstance has followed a cut throat. The plan of covering the opening with a small piece of skin from the neck appears to be a simple and successful mode of completing the final cure. The duty of restraining the first hæmorrhage in this case did not come under my notice; but I think it may be suggested, in conclusion, that no surgeon should ever be without a solution of the perchloride of iron. Its styptic power is so remarkable, that I have myself stopped the hæmorrhage from a wound of the profunda femoris by its aid; and do not doubt that, with a pledget of lint saturated with this fluid and by pressure, even a wound of the carotid may be sufficiently controlled to give time for operative procedures."

Mr John Hunter, of Manchester, reports a case of *Numerous Calculi in the Female Bladder*. He says:

"On visiting her again, and introducing the catheter, the bladder seemed to be full of stones. All her former symptoms had returned in an aggravated degree, and the pain she was suffering was intense. The next day I introduced (having in the meantime exhibited palliatives) a piece of gentian root,—a hint derived from the French,—cut smooth to the exact size of the urethra. After being left in for twenty-four hours, the calibre of the urethra was enlarged, so that the little finger could be introduced, and with a forceps I was able to get away a great number of small stones and *débris*. These were also of phosphatic formation. I repeated my efforts, the patient being under the influence of chloroform, on the two succeeding days, washing out the bladder with tepid water, but found that one stone resisted all attempts either to remove or crush it. Under these circumstances, and with the able assistance of my friend Dr Brabazon, I proceeded to operate in the following manner:—The patient being under the influence of chloroform, I introduced into the urethra a concealed bistoury, and made two incisions, right and left, towards the rami of the pubis. Not being yet able, by the additional space thus afforded, to get away the stone, I made a curved forceps, introduced through the urethra, project in the vagina, and cut upon it. Still, however, there was not sufficient room, the forceps grasping the stone being locked in the wound in attempts being made to withdraw it. At last I was obliged, with one cut, to throw the wound and the urethra into one, when I was able to extract the stone, which is nearly the size of a hen's egg, and lithic acid in character. The after-treatment consisted in perfect rest, tying the knees of the patient together, strict cleanliness, tonic medicines, and good diet. There were no bad symptoms following the operation, the discharge from the wound gradually abated, the parts being left entirely to themselves, and in four weeks and two days after the operation,—namely, on the 31st of May, 1860, when paying my last visit,—the patient was found to be free from pain, the wound perfectly healed, no discharge, the urine quite healthy, and the bladder able to retain its urine for three hours. The general state of the patient was also quite satisfactory."

Dr J. Y. Simpson continues his Lectures on the *Diseases of Women* in the 'Medical Times

and Gazette.' The special subject is Dropsy of the Fallopian tube. We quote his remarks on the diagnosis — nothing satisfactory being known as to prognosis and treatment.

"To resume, then. The characters by which you will be enabled to determine whether a cystic tumour lying in the pelvis is due to the dilatation of a Fallopian tube, are, shortly, these:—

"First. *Its free and independent Mobility.*—The tumour is freely moveable in the cavity of the pelvis, and does not move synchronously with the uterus; but, on the contrary, it remains at rest when the womb is moved, and can be readily moved about by the exploring finger when the womb is kept firmly fixed, either by the hand placed above the pubes, or better still, by means of the uterine sound introduced into its cavity.

"Secondly. *Its elongated Form.*—As the fluid collects in and distends the tube in nearly all its length, the resulting tumour is of an elongated conical form, with the rounded base corresponding to the obliterated fimbriated extremity and the apex at the upper angle of the uterus.

"Thirdly. *Its wavy Outline.*—In all cases the surface of the tumour feels more or less undulating and indented, for, in most instances, the distended tube is folded once or oftener on itself, and tortuous; and when it is not thus wavy and convoluted, the smooth outline is interrupted by the pressure of bands of plastic fibrine stretching over and indenting it.

"I have also referred to the comparative size of the tumour and its situation in the ordinary position of the Fallopian tube as guides—though certainly of less value—in enabling you to discover and recognise the disease. If you have satisfied yourselves in any case as to the existence of the characteristics which I have attempted to portray, you may proceed at once to confirm your diagnosis of the disease, and to initiate your treatment by introducing an exploring needle into the interior of the cyst, and examining the fluid that escapes, which, as I have stated, is usually perfectly limpid and clear. It is, no doubt, a matter of considerable difficulty to make out clearly in certain cases the actual presence of a tumour with all the characters I have described; and to decide positively that it is a dropsy of the Fallopian tube will demand a certain amount of experience on your part, and no small care and caution in conducting the examination. But the difficulties of the case will be lessened, and the diagnosis will be rendered more certain, if you always take the precaution to investigate the pelvic organs by means of both hands simultaneously—one being placed over the fundus uteri, and pressing down upon the pelvic organs through the abdominal walls, while two fingers of the other hand are passed into the two canals at the outlet of the pelvis, for the purpose of examining the state of its contents from below. Where the patient has previously had a family, the abdominal walls are soft and flabby, so that the pelvic organs can be readily felt through them; and where they are firmer and less yielding, by putting the patient under the influence of chloroform they will be so far relaxed as to enable you to have all the parts thoroughly at command."

Dr Goodfellow contributes the first of three Lectures on *Bright's Disease*, and Dr Ogle reports a case of *Delirium Tremens* in which acetate of morphia was injected into the cellular tissue of the arm. We take up the report about the middle of the case.

"June 10, Half-past Five a.m.—The nurse sent for me, as he had something like a fit, turned cold and pale. He tells me he has slept comfortably, but on cross-questioning admits that he can remember very little of what has transpired during the night. The nurse says he has had no sleep, has been out of bed two or three times not knowing what he did. Pulse is above 100, is 136 when he sits up, and is more feeble. The conjunctivæ are injected, and the pupils are, as they have been hitherto, dilated. Tongue dark, venous in colour, not so woolly as yesterday. Skin warm. Has passed about an ounce of urine, not more. I remain with him two hours, trying to compose him with chloroform, for the nurse says that the chlorodyne seemed to excite rather than soothe him. I administer the chloroform on my handkerchief; the composing effect is very transient; as soon as ever I try to press it, he becomes excited, and says he will have no more, so I give ʒss of chlorodyne in an ounce of brandy, and leave twenty minims to be taken at noon. His pulse (probably the right), during the inhalation of the chloroform, became rather more slow and steady. Sponging his forehead and behind his ears quiets him more than anything.

"Three p.m.—Pulse (probably the left) 112, feeble. Is tolerably himself now, but does not remember my morning visit. Has been sick twice after the medicine; but his pupils are slightly contracted. His appetite is not amiss.

"Ten p.m.—He is perspiring profusely, probably from the resistance to the attendants. It requires two men to hold him. His pupils are as dilated as ever; he is talking about business matters incessantly. I give chloroform another trial (for two hours). Once only he passed beyond the stage of excitement, but at the same time his breathing stopped, and he became rather dark in the face, so I was afraid to push it; his pulse varied very much. I, therefore, inject into the cellular tissue of the arm solution of morphia ℥ vj. (=gr. j. according to Hunter's recipe). He is quiet almost immediately, so far as to lie still without being held, but he continues talking. After waiting an hour I resolve to inject another dose, but the pulse being feeble I give an ounce of brandy in soda-water, and while I am preparing my syringe in the next room, I have the gratification to hear him snore. Breathing sixteen in the minute, quite regular. Pulse 120, full; intermits occasionally. The pupils are only the size of a large pin head.

"11th, Ten a.m.—Nurse reports that he ceased to snore soon after I left, when he turned over on to his side, and that he slept comfortably for five hours. On waking he did not know where he was, but was soon reassured, asked for soda-water, and turned to sleep again. He wakes up as I enter the room, if he was not awake before; says he has had refreshing sleep, and that he is pretty well; but he looks towards the door in an expectant, half-frightened way; and when he dozes, which he is quite ready to do, his hands are at work feeling as if for something which he cannot find. His pupils are slightly contracted, about as much as yesterday at three p.m. Pulse intermits when he is asleep, not otherwise, I think; it is not so full nor so frequent; it is quicker and weaker when he sits up. He has not passed water since the last note; the bladder is not much distended; he says that he cannot usually make water readily, except when at stool. He asks for, and is allowed, a couple of eggs for breakfast.

"14th.—Circumstances made it desirable that should be at home as soon as possible. I gave permission, on the condition that he abstain from business for a fortnight at least; and go with his family to the sea-side; and not touch wine, beer, or spirits, except his Medical attendant order it for him.

"*Remarks.*—Some surprise may reasonably be felt, both that I did not give stimulants more freely, and that I did not persevere with the chlorodyne. I think it quite possible that, if the chlorodyne had been given in water instead of with the nitric ether and acetate of ammonia, it would not have made him sick; and it was the idea that the opiate made him sick which made me hesitate to press it. Also, the apparent advantage of the brandy after the injection of the solution of morphia, makes it probable that more brandy might have been given with advantage. On the other hand, the small amount of stimulus that was given made it much more easy for me to insist upon a total abstinence when he was convalescent; and the marked benefit of treatment by injection into the cellular tissue is the more striking, in that a single grain was successful when chloroform had failed, and that it was used at a time when the effect of any opiate that had been administered had entirely passed away. It is but justice to add, that it was owing to the papers of Mr Hunter which have appeared in the 'Medical Times and Gazette' that I was led to try this mode of administering morphia in delirium tremens."

Dr Stutter contributes to the same journal a *Case of Extra-Uterine Fœtation* in which the child was successfully removed by abdominal section. We extract it:

"The subject of the following case is a delicate woman, aged 40, the mother of four children. Her first three labours were natural and easy; but her last, which took place ten years ago, was a breech presentation, and was attended with severe suffering, and followed by inflammation, which confined her to her bed for three months. After this her catamenia continued regular until October, 1858.

"In the beginning of December, 1858, two months after the suspension of her menses, Mrs T. was under my care on account of a severe illness, many of the symptoms of which closely simulated those of strangulated hernia. She had general abdominal pain and extreme tenderness over the whole belly, which was, however, most marked in the left iliac region. There was incessant vomiting, constipation of the bowels, great thirst, and a quick small pulse. On the second day the vomiting matters were of stercoraceous character. Opiates, enemata, and poultices to the abdomen were the remedies employed, and after a few days the symptoms mentioned passed off. In the latter part of the month, however, she had an almost similar attack, and a third occurred in the end of January, 1859. At this time there had been no morning sickness, and the breasts remained flabby and undeveloped. In the beginning of February, however, I obtained positive evidence as to her condition by discovering the pulsations of the fœtal heart, and about the middle of the same month she quickened.

"Early in June, 1359 (eighth month of pregnancy), Mrs T. again had a severe attack of the kind described above. In the beginning of July an illness less severe in character than the former ones, but accompanied by much forcing pain and procidentia, occurred; and during this she ceased to feel the movements of the child, and the latter never afterwards returned. At this period her abdomen was of a size equal to that of the full period of pregnancy; it was generally tender, and especially so on the left side: the fœtus could be very distinctly felt through the parietes. During the prolapse which occurred I found the os uteri open. The cervix formed a canal with the body of the uterus, into which the sound was admitted for a length of an inch and a half. There was an escape of blood from the interior of the uterus, and a shreddy mucus continued to be discharged for some days afterwards.

"After the illness last adverted to, Mrs T. was not able to leave her bed. Through July and August she continued to get more and more feeble, and was troubled with vomiting of almost everything that was taken. Her pulse ranged between 140 and 150; her mouth became covered with aphthæ, and it was evident that she was fast sinking. On several occasions, Mr Ray, of Dulwich, had kindly given the advantage of his able advice, and to him I was indebted for the first suggestion as to the real nature of the case. At length I determined to remove the fœtus by incision through the abdominal walls, a proceeding which Mr Ray fully agreed with me in considering justifiable and necessary.

"The operation was performed on Monday, August 21, Mr Ray and Dr F. H. Hewitt assisting me. The patient's state at the time may be described by saying that she was almost moribund, troubled with constant hiccough, and bathed in cold perspiration. For several days she had vomited almost incessantly, and had also suffered from profuse diarrhœa. The surface of the abdomen below the umbilicus, that is, over the most prominent part of the tumour, was becoming discoloured, and there was distinct fluctuation to be felt. Chloroform having been administered, I plunged a trocar into the most prominent part of the tumour, in the median line, a few inches below the umbilicus. About sixty ounces of turbid brownish fluid escaped. This fluid had a fetid odour. With a bistoury passed down through the abdominal wall by the side of the canula, a free incision was made directly upwards, and another downwards, to the extent together of about six inches. The back of the child now presented. The hand having been passed into the abdomen, the child's feet were seized, and extraction was accomplished without difficulty. The child was a female, weighing five and a half pounds: skin peeling off, and the body undergoing decomposition, and smelling very offensively. The placenta was found to be firmly adherent over the surface of the intestines, and no attempt was consequently made to get it away.

In dividing the abdominal parietes no cyst-wall had been noticed, the structures being all closely agglutinated by inflammation. Neither omentum nor coils of intestine were exposed to view in the operation. The latter were probably protected by the placenta, which was of large size, and spread out over them. Having sponged out the cavity, the edges of the wound were loosely brought together by strips of plaster, and sponge having been placed over it, the whole was confined by an abdominal bandage.

"I may condense my report of the subsequent progress of our patient. For about a fortnight she remained in an extremely critical condition, though each day gaining a little. The irritability of stomach subsided, and she became able to take larger quantities of food. The cavity which had contained the child suppurated freely, and was regularly syringed out with warm water twice daily. Opiates, tonics, and stimulants were used as occasion required. The placenta loosened, and was removed *en masse* on the fifth day. After the placenta had come away her improvement was more rapid. In about three weeks from the date of the operation she might be considered out of danger; in six weeks the wound was closed; and in three months she left her sick-room, and was able to resume her household avocations.

"I may state that Mrs T. menstruated four months after the operation, and has continued to do so regularly since. She is now (eleven months afterwards) in her ordinary health. The cicatrix in the abdominal wall is very small, and there is no perceptible induration or enlargement beneath it."

The 'Dublin Medical Press' contains a report of *Surgical Cases* by Professor HARGRAVE. We quote it:

"Effusions of blood the result of injuries may present one of the following appearances:—1st. Ecchymosis, more or less extensive, indicating its characters by the alteration in colour of the skin, and limited principally to the capillary vessels. 2nd. A general diffusion of blood through the parts contused, with more or less pitting on pressure, and not for some days causing any discolouration of the integument; this occurs when it is effused in the deeper tissues close to the bones, after which period the change in the colour of the skin often becomes very similar to what is seen in superficial ecchymosis. 3rd. The blood may be located and circumscribed in a cavity, giving all the characters of the bloody tumour or sanguineous deposit; when it is effused under the scalp, forming the peculiar characters of this kind of tumour so well known in this region, so likely to be confounded with depressed fracture of the cranium. This kind of tumour is generally considered special to this region; still, where blood becomes effused from violence over bones, or other resisting surfaces in other situations, we find it presenting analogous symptoms, giving rise to the possibility of an error in diagnosis. In a case of this kind over the fibula, the bone presented all the phenomena as if a circular piece of it was driven into the interosseous space by a punch, surrounded by a firm resisting rim; but the hardness and crepitus which here were present disappeared under pressure, returned after a little time, again by the same means disappeared, which led me to a diagnosis which the subsequent treatment proved to be correct. A more remarkable case was in a man admitted November 12th, 1857, John M——: he was carrying a heavy trunk across his loins, and made a false step, which caused it partly to slip from its position, but not to fall off; the result was, the cellular membrane connecting the skin to the lumbar region was lacerated, and a large quantity of fluid blood was effused in this region, forming a bag or sac as large as my entire hand. The circumference of this tumour was as well defined in resistance by a firm ring as any scalp bloody tumour that was ever presented to the practitioner; this large quantity of blood never caused any cutaneous discolouration, and was completely absorbed in one month, being discharged from hospital December 12th.

"When these tumours are very deep-seated, they occupy a long time before they come to the surface containing blood; sometimes the colouring matter of it is absorbed, and after the lapse of many months the characters of a serous cyst are recognized by the surgeon, who, by a careful investigation of the case as to its history, will form a correct opinion of its formation; while, in some rare cases, the fluid contents of the cavity are absorbed, and a reddish brown kind of tumour is the consequence of the accident, and in others, still more rare instances, the effused blood has remained for years dormant, undergoing no alteration in its physical qualities, the cavity when opened presenting the fluid of its normal appearance. The following cases are examples of a long period elapsing before the tumour in any way approached the surface:—Patrick F——, a brewer's labourer, was admitted into hospital, having met with the following accident three months before admission: the lower part of the right thigh was severely bruised, almost crushed, between two porter barrels. On examination, a large fluctuating soft swelling was detected above the knee and to the inner side of the thigh, evidently containing a fluid which was considered to be a purulent collection; it was very superficial, with no tegumentary discolouration. This man was of a highly sanguineo-nervous temperament. Before the abscess was opened he asked for chloroform, and when *slightly* under its influence I passed a lancet into the most prominent part of it, avoiding the saphena vein; pus first issued from it, then mixed with fluid, and some coagulated blood. The wound was immediately closed and maintained by suitable appliances. A smart attack of irritative fever followed, which required some days to subdue; cold evaporating lotions were applied to the swelling, conjoined with rest, and bandages carefully applied; the contents were absorbed, the man leaving the hospital convalescent, and experiencing no inconvenience from a bloody tumour containing pus being opened.

"The next case is one of some novelty:—James K——, a discharged soldier, admitted into the City of Dublin Hospital, August 30, 1858, for secondary syphilis. In the following month of January he called my attention to a very prominent swelling occupying the left nates, bulging up into the gluteal fossa; in fact, making it convex. No uneasiness or distress of any kind, but evident fluctuation. As abscesses at that time were almost of daily presentation, both at the dispensary and formation in the hospital, I passed a lancet into it, when a quantity of grumous blood, speckled with pus, issued from the wound, and continued to flow through it, which was immediately closed and so maintained. On questioning him if he ever received an injury on this region, he stated he was at the relief of Lucknow in September, 1857, was struck with the butt of a musket on this part, and was felled by the blow. On recovering himself he was able to walk, though badly; the effects of this injury so soon subsided that he took no further notice of it, when, after the lapse of some months, the swelling began to appear to which he called my attention, which I opened as an abscess, but in reality a sanguineous tumour which lay dormant for nearly sixteen months, and was slowly and most chronically passing into the suppurative stage, as evidenced by the purulent dottings mixed with the blood. He experienced no inconvenience whatever from its being opened; the wound healed, the swelling subsided, and he left the hospital convalescent, February, 1859. This man suffered no irritative fever of any kind; the former had a smart attack of it—he was of sanguineo-nervous temperament, the soldier of a bilious one. Could these temperaments be the cause of the difference in the results of opening these tumours?

"In the treatment of sanguineous effusions, the abstraction of blood is often indicated, either by leeching, by cupping, or by venesection. The two first have almost superseded the last. Venesection may be considered the exception in medical practice in its widest sense as a remedial agent at the present day. Of late this practice has been much canvassed and completely rejected by some practitioners of authority, and is likely to become a mere historic record of what was formerly the rule. I confess that at the period I entered the Profession venesection was actively, and *I will add successfully, practised, cum pleno rivo ad uncias viginti, vel ad deliquium animi*, and many recoveries and few deaths were the result. Of the juvenile operators I might say of myself, *quorum magna pars fui*. My early training and observations then made on this practice is so implanted in my mind that I have not abandoned the lancet, as others have done, but use it not in the same heroic way it was at the time I refer to. We all acknowledge that a remarkable change has come over our organisation; the *vis vitæ* is no longer above par, or at par, but in most cases below it. Is it for this reduction of our forces that so useful a means of combating disease is to be abandoned? Certainly not; but proportion the quantity of blood to be drawn to the strength of the patient, and no unpleasant result, but benefit, will follow from it. To prevent the possibility of my being misunderstood, in place of taking a dash of blood of twenty ounces at once, as was formerly the hospital parlance and practice, let but from four to six be abstracted, and much relief will attend it, by which the oppressed organ and condition of the parts injured will be relieved; while the venous vascular system being quickly emptied, a stimulus is thus given to the absorbent system, and the rapid disappearance of effused fluids follows this practice, and which I have no reason regret up to the present time; while the scarificator will not be required with its markings, nor the annoyance of the application of leeches be endured, or the unpleasant consequences which sometimes follow their bites when made in the integuments which cover extravasated blood. I feel satisfied that all classes of practitioners have gone into the opposite extreme by ignoring the lancet too much. I have been speaking of venesection as applied to the bend of the arm; but there is another—namely, that of the external jugular vein—an operation in some cases of great value, which not many young men passing from the schools into practice know how to perform single-handed and with success, without any dread of air being suddenly absorbed into the vein and killing the patient with intense rapidity by being hurried along it to the heart. The feeling alone of being considered egotistical prevents me giving such directions for opening the jugular vein, apparently a simple operation, as would guard against all mishap.

"At some future period I may assign my reasons for the decadence of the *vis vitæ* at present so patent to all observers; but it is only temporary; the coming-on-cycle will show to those who see it that the human system will again rally and with benefit will bear the lancet as a remedial agent."

MURIATE OF AMMONIA IN NERVOUS CEPHALALGIA.

Professor Barallier, of Toulon, reports that within the last three years he has administered this substance in 259 cases of nervous cephalalgia, and with success in 202 of these. He gives forty-five grains, combined with mint-water and syrup of orange-peel, divided into three doses, to be taken at intervals of half an hour, amendment commencing after the first dose, and the third frequently not requiring to be taken. To prove effectual, however, the remedy should not be given at the very commencement of a paroxysm, but when it has acquired great intensity. This agent not only gives relief to the urgent pain of the paroxysms, but, after having been had recourse to on several occasions, diminishes the number and frequency of these. To be of use, it must not be indiscriminately used for every cephalalgia; and the result of the analysis of M. Barallier's experience leads to the following conclusions: 1. The muriate almost constantly dissipates paroxysms of idiopathic migraine, and of migraine consecutive to too abundant menstruation. 2. It is powerless in the hemicrania which is dependent upon irregularity or suppression of the menses. 3. It is tolerably successful in cranial pains dependent upon disorder of the stomach, and in the accidental cephalalgia frequent in women and feeble persons under the influences of sudden changes of the atmosphere, prolonged intellectual labour, or moral emotion. 4. It operates beneficially in cephalalgias consecutive to repeated paroxysms of intermittent fever, those which are observed during the decline of severe fever, and in the course of the irritative period of typhus.—'Bull. de Thérap.,' February 11, 1860, and 'British American Journal.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, JULY 25, 1860.

ST GEORGE'S HOSPITAL IN TROUBLE.

Alieni appetens, sui profusus. Sallust's description of the character of Catiline is extensively applicable in modern England. The spirit of that description is so prevalent that it has become superior to apology, and there are men who do not hesitate to elevate into a rule of right a characteristic that was considered, even in the days of the commencing corruption of old Rome, as the most striking evidence of a bad character. We have, indeed, organised the vice into a system, and we prostitute the holiest causes to feed the passion. The social end of all men seems to be to get money, and the most successful method of attaining that object to squander it. There is a spirit of recklessness at the bottom of this policy. The advertiser throws all his capital into a grand issue of bills and posters, in the hope of striking the imagination of the public and entrapping their confidence. If he fail, he robs his creditors; if he succeed, he may become rich, or, at least, win the credit of being a clever fellow. The prize is worth the risk; and the risk is, after all, not great to a man who places but a small value on that which he possesses. Hope is stronger than conscience; and if success follow, or if even the semblance of it can be maintained, the speculator's conscience will appear to the world quite as sensitive, and to be as strictly regulated by the canons of moral and religious discipline, as that of the most virtuous exemplar of Christian rectitude. There are Sir John Dean Pauls among us yet,—good men, charitable men, until they shall be found out!

There is little difference between these gentlemen and your Robsons, Redpaths, and Pullingers; the main distinction being, that whilst the latter are greedy of other people's money, they also spend with profusion the same money, *not* their own. It is risked from the same motive,—to get more, to keep up appearances, to balance accounts, or to return that which they have misappropriated. The governing moral law among all these men seems to be —"Spend!" No matter whose may be the money—"Spend!" Be it the man's who, foolishly confiding in your rumoured wealth and integrity, made you the trustee of his hard-earned savings—"Spend!" Be it the man's who for years has taken you into his confidence, and deposited with you the key of his coffers and the care of his reputation—"Spend!" The money must try its luck, and the reputation must take care of itself.

The idea that an extravagant expenditure is necessary to obtain funds, and that debt is a sure first step to solvency, has become a guiding principle in the management of some of our charitable institutions. Here the baneful principle has been organised, and carried out without shame or remorse. Corporations, as Lord Thurlow said, have no conscience; consequently, no nice qualms of feeling in the commission of rash or questionable acts.

It was with much regret that we read a letter last week in the 'Times' newspaper from a "Governor of St George's Hospital," in which the Board of that Charity were directly charged with having systematically acted upon the most mischievous recklessness in the management of their affairs. Had we not read this letter in the 'Times,' we could not have credited the statement that so respectable a body as the Governors of this Hospital undoubtedly are could have knowingly and habitually handled the funds in so ruinous a manner.

We are informed that thirty years ago the income of this Hospital was 10,000*l.* a year, which was made up in the following way—viz.: 4,000*l.* from annual subscriptions, 4,000*l.* from the interest of 125,000*l.* in the funds, and a small amount from the rental of a house, and 2,000*l.* more from small legacies and donations. The marvel is yet to be stated. Between the years of 1830 and 1859, additional legacies, donations, and life-subscriptions have been received to the amount of 225,000*l.*, of which 25,000*l.* have been expended in building a new Hospital; leaving the Governors the large sum of 200,000*l.* to deal with for the maintenance of the Charity.

Now begin the troubles and follies of the Board. Having erected a splendid structure—too small indeed for their ambition, yet too large for their means—they desired to support it in the grand style which its pretensions seemed to make obligatory. Here were the temptation and the difficulty. Like many men who have built large mansions with clock towers and oriel windows to gratify their ostentation without due regard to their income, they were induced to gratify their ambition by living upon their capital, and the result is that such a course of imprudent prodigality has reduced them to a condition of bankruptcy and financial ruin. The large sum of 200,000*l.* is gone—gone irretrievably! As the "Governor" shows, had this noble sum been placed in public securities, the interest, together with the previous income, would have sufficed to endow the Hospital in perpetuity, and to make it entirely independent of eleemosynary contributions. Now, alas! that hope is forfeited; and instead of being independent, the Governors are suing for public charity to help them out of the mire of trouble into which they have been plunged by their own improvidence. Never did a culpable policy more quickly bring round its own punishment. It is condemned in the face of all wise and prudent men; and the Governors are, we trust, ashamed of the peril into which they have dragged the affairs of their noble Charity.

The example which such a Charity as St George's presents to humbler institutions of a like kind, and to the public at large, is more pernicious than even its results upon the Hospital itself. It encourages a practice of improvident expenditure and of perpetual indebtedness—an immoral course, whether exhibited in the affairs of individuals or of Boards. Economy is another word for justice,—by what term shall we characterise habitual extravagance? For many years the expenditure of the Hospital has been 6,000*l.* per annum above its income: is it likely that the public can be whipped up by means of appeals, and dinners, and fancy fairs, to subscribe an additional 6,000*l.* per annum to meet the current expenditure? If not, then the benefits of the Institution must be considerably diminished, several wards must be closed, and a blight will rest upon the Institution from which it may never recover.

Surely "Hospital Reform" is not a vain cry. We believe that this extravagant expenditure—which, when it does not ruin an Hospital, as it may in this case, nevertheless diminishes its usefulness in behalf of those classes for whose benefit these Charities were originally erected—is incurred generally to maintain that huge parasite—the OUT-PATIENTS' Department—a department which is attended by more evils and abuses than we can now find space to describe. We shall, however, revert to this subject, and do not mean to spare a system which demoralizes the industrial classes, degrades the Medical Staffs, and wrongs the Private Practitioners.

SUMMARY OF THE WEEK.

THE DUBLIN COW-POCK INSTITUTION.

A fortnight ago we drew attention to the shortcomings of the Dublin Cow-Pock Institution, and suggested that it was a proper subject for Parliamentary inquiry: we have now the satisfaction to state that Mr BRADY has brought the subject under the notice of Parliament, and that Mr CARDWELL, the Chief Secretary for Ireland, has promised that the fullest inquiry shall be made into the matter. We hope that the interference of the Government will lead to a re-organisation of

this establishment, so that it may be better adapted to fulfil the ends it affects to serve. That any institution supported by *public* money should be permitted to charge a Medical Practitioner two shillings and sixpence for *two points* of lymph, is so outrageous that we cannot conceive that it will be permitted by the Government longer than the moment when it becomes publicly known.

THE INTERNATIONAL STATISTICAL CONGRESS.

The Fourth Session of this Congress has been held at Somerset House, and has been attended by *savans* from all the countries of Europe, and from the chief of our colonies and dependencies. The Prince Consort inaugurated the Session with a very able address, in which the application of statistical science was well defined, and its importance indicated. We are sorry that we cannot reproduce the entire speech; but some paragraphs of it deserve to be noticed. After adverting to the abuses of statistics, and stating that they fall short of participating in the highest view of all science—viz., the discovery and expounding the laws which govern the universe—but that, nevertheless, they render self-apparent those discoveries in the rigid figures placed before the inquirer; and after defending the importance of statistics, as evidenced in the fact, that although the fallacies traceable to them may be decried, yet they continue to be employed as the basis of inquiry by all searchers after truth; he observes:

"We hear it said that its prosecution leads necessarily to Pantheism and the destruction of true religion, as depriving, in man's estimation, the Almighty of His power of free self-determination, making His world a mere machine, working according to a general pre-arranged scheme, the parts of which are capable of mathematical measurement, and the scheme itself of numerical expression; that it leads to fatalism, and therefore deprives man of his dignity, of his virtue and morality, as it would prove him to be a mere wheel in this machine, incapable of exercising a free choice of action, but predestined to fulfil a given task, and to run a prescribed course, whether for good or for evil. These are grave accusations, and would be terrible indeed if they were true. But are they true? Is the power of God destroyed or diminished by the discovery of the fact that the earth requires 365 revolutions upon its own axis to every revolution round the sun, giving us so many days to our year, and that the moon changes thirteen times during that period, that the tide changes every six hours, that water boils at a temperature of 212 degrees according to Fahrenheit, that the nightingale sings only in April and May, that all birds lay eggs, that 106 boys are born to every 100 girls? Or is man a less free agent because it has been ascertained that a generation lasts about thirty years, that there are annually posted at the post-offices the same number of letters on which the writer had forgotten to place any address; that the number of crimes committed under the same local, national, and social conditions is constant; that the full-grown man ceases to find amusement in the sports of the child? But our statistical science does not even say that this must be so; it only states that it has been so, and leaves it to the naturalist or political economist to argue that it is probable, from the number of times in which it has been found to be so, that it will be so again as long as the same causes are operating. It thus gave birth to that part of mathematical science called the calculation of probabilities, and even established the theory that in the natural world there exist no certainties at all, but only probabilities. Although this doctrine, destroying man's feelings of security to a certain extent, has startled and troubled some, it is no less true that, while we may reckon with a thoughtless security on the sun rising to-morrow, this is only a probable event, the probability of which is capable of being expressed by a determined mathematical fraction. Our insurance-offices have, from their vast collection of statistical facts, established to such a precision the probable duration of man's life, that they are able to enter with each individual into a precise bargain on the value of this life; and yet this does not imply an imperious pretension to determine when this individual is really to die. But we are met also by the most opposite objection, and statistics are declared useless, because they cannot be relied on for the determination of any given case, and do only establish probabilities where man requires and asks for certainty. This objection is well founded, but it does not affect the science itself, but solely the use which man has in vain tried to make of it, and for which it is not intended. It is the essence of the statistical science that it only makes apparent general laws, but that these laws are inapplicable to any special case; that, therefore, what is proved to be laws in general is uncertain in particular. Herein lies the real refutation also of the first objection, and thus is the power, wisdom, and goodness of the Creator manifested, showing how the Almighty has established the physical and moral world on unchangeable laws conformable to His eternal nature, while He has allowed to the individual the freest and fullest use of his faculties, vindicating, at the same time, the majesty of His laws by their remaining unaffected by individual self-determination."

These are admirable observations, always timely and never misplaced. His Royal Highness then proceeded to show the conditions under which statistical science must be prosecuted, and concluded a very able address amid the cordial approbation of his audience.

THE VOLUNTEER FORCE AND MEDICAL STAFF.

The rapid formation of a Volunteer Force has involved the necessity of providing it with a large Staff of Medical Officers. We, of course, assume that our Riflemen mean fighting, if ever the opportunity or need should occur; and as fighting and campaigning mean sickness and wounds, the Force must be necessarily provided with an adequate number of Surgeons. This is a question for the War Office. Surgeons cannot be expected to give up their private engagements without some kind of recognition. We understand that the Government intend to make arrangements with respect to this matter, and we hope soon to see an adequate Medical Staff associated with the Volunteer Force.

THE UNIVERSITY OF ABERDEEN.

For many years a war has been waged between King's College and Marischal College, Aberdeen; the former endeavouring to extinguish the latter, and the latter to make good its right to grant degrees as a *bonâ fide* independent University. The contest was an unseemly one; and as it was damaging to both interests, the Government at last appointed Commissioners to arrange the questions in dispute. These gentlemen decided for an amalgamation; but as this would be the extinction of the lettered pride of both Colleges, they resisted the proposal, and contended for the maintenance of the Institutions as independent schools, in favour of which there is a considerable amount of plausible argument. The Government was, however, obdurate, and the two Colleges are to be amalgamated under the title of the "University of Aberdeen;" and we hope the change will add to the dignity of the old city, and increase the prosperity of the united Colleges.

THE BRIGHTON "RUBBER."

A remarkable case appears in our Legal Intelligence, under the heading "Gardner *v.* Harrap," in which an illegal practitioner has for once met with his deserts. This person is the famous Brighton "rubber" and "pickler," and, happening to have the care of a patient who was suffering from chronic rheumatism of the knee-joint, and, as appears in evidence, also a condition of brain described as being "very soft," he managed to obtain a very large amount of fees as a reward for his scientific manipulations. Mr Gardner, however, not being so "very soft" as he chose to represent himself, brought an action against Harrap for malpraxis, and the latter was mulcted in the sum of 300*l*. This was a very sensible decision.

REVIEWS.

Diseases of the Heart; their Pathology, Diagnosis, and Treatment. By W. O. Markham, M.D. Second Edition.

The Author of this work has long distinguished himself for his opposition to that method of practice represented by mercury and bloodletting. The Medical Journals bear frequent record to his earnestness in this controversy; and although, at first, his supporters were few, he has now the satisfaction to find that the views he has advocated have a very extensive prevalence. In no class of diseases is a more cautious and philosophical treatment required than in those of the heart. Time was when bleeding was systematically resorted to in these affections, and imperatively so should a fit occur in consequence of extensive disease of this organ. So settled was this maxim of practice, that if a Medical Practitioner had neglected to bleed a patient in such an exigency, and a Coroner's Jury had been empanelled, he would in all probability have been censured for his want of skill, and lost his character. Now all these things are changed, and Medical men enjoy greater liberty of judgment—thanks to Dr Todd, Dr Bennett, and in his degree, too, Dr Markham. Medicine is yet on the threshold of great improvements. New principles derived from the rich fields of pathology, and a more faithful observance of natural phenomena, are making their way into practice and revolutionizing all our old dogmas. There is a fear, of course, that the new doctrines will be carried rashly to extreme propositions, and that a reaction will be necessary to trim the balance; but it does not appear to us that the modern views have received that general recognition, or, as a rule, have been so unwisely urged, as to call for the discouraging restraint of severe criticism. We have no doubt that the practice of Medicine will derive great advantage from the cultivation of pathology, and from the demolition of that unquestioning confidence in the agency of mere drugs in all forms and shades of disease. Disease is not to be cured by drugs alone, but by whatever influences the human body through its varied functions. This is the philosophical way of regarding the

practice of Medicine, and provides the only effectual weapon that will extinguish prejudice and quackery.

This treatise commences with a description of the Inflammatory Diseases of the Heart, then treats of vascular disease and the various murmurs, with fatty degeneration, angina pectoris, cyanosis, and functional affections, ending with diseases of the aorta. There are five Appendices, severally treating of the Uses of Venesection, Fibrous Arterial Clots, Sounds of the Heart, Impulse of the Heart, and Rupture of the Heart.

With reference to the complications of pericarditis, we find these remarks:

"The cause of *rheumatic pericarditis* is, as I have already said, the cause which excites the rheumatic fever. Statistics have not yet given us any sure information with regard to the frequency of pericarditis in rheumatic fever. M. Bouillaud and Dr Hope found pericarditis present in about one-half of their cases of acute rheumatism. Dr Taylor makes the number about one in nine; Drs Budd and Latham make it about one in eight.

"Results, however, on this subject, derived from the observation of cases which have been taken indiscriminately, without regard to age or sex, are of very little value; for it is a fact, that at certain periods of life the *coincidence* of rheumatism and pericarditis is much more common than it is at other periods. Thus, adult persons attacked by acute rheumatism are infinitely less liable to cardiac complications than the young are. After the age of thirty, pericardial and endocardial inflammation are, comparatively, rarely met with as the associates of rheumatism; whilst, on the other hand, before the age of twenty, and in early life, they are more frequently present than absent, in connection with that disease.

"Observation, indeed, shows: that rheumatic pericarditis attacks those of weak rather than of strong constitutions; that it is more common in the delicate and young, than in vigorous persons at the prime or middle periods of life; and that the degree of inflammation—that is, the general febrile reaction and the local exudation—is also greater in them than in the strong; and that it is often especially severe in young females. Climate, also, may have something to do with the matter; for, as Dr Chevers tells us, the association of pericarditis and endocarditis with acute rheumatism is very rare in India, although articular rheumatism is very prevalent there.

"The causes of *non-rheumatic* pericarditis are of two kinds, local and constitutional. The chief local causes are, cancerous diseases, arising within the sac, or, as much more frequently happens, spreading into it from some of the parts around the pericardium; tuberculosis, pleuritis, and peritonitis, by acting as local sources of irritation; abscesses of neighbouring organs or parts, and hydatid cysts, by opening into and discharging their contents into the sac.

"The chief constitutional causes, or, to speak more correctly, the diseases in connection with which the non-rheumatic pericarditis is observed, are diseases of the kidney, pleurisy, pneumonia, pyæmia, scarlatina, peritonitis, and variola.

"Bright's disease of the kidney has been especially referred to by authors as a very frequent exciter of the inflammation. My own experience does not at all agree with this conclusion. Out of a great number of cases of kidney diseases which have come under my observation in the pathological department of St Mary's Hospital, I have met but with very few where there existed any recent signs of pericardial inflammation. The same results have been arrived at in Edinburgh, where kidney disease is very common. Professor Bennett ('Principles and Practice of Medicine') tells us, 'that in none of his cases of pericarditis has there been a complication with Bright's disease. Dr Christison also says, 'that pericarditis is rarely seen among the sequelæ of kidney disease.' Frerichs also ('Die Brightische Nierenkrankheit,' p. 120) found inflammatory exudations in the pericardium in only thirteen out of two hundred and ninety-two cases of Bright's disease."

Perhaps there are few pathological points more interesting or important than the relation of heart affections with kidney disease. Much is yet to be determined on this point. With reference to the comparative mortality of complicated and uncomplicated cases, Dr Markham observes:

"*Non-rheumatic, pericarditis*, on the other hand, occurs at a later period of life than the rheumatic kind. Forty-two was the average age of persons affected by it in twenty-four cases reported by Dr Ormerod. The subjects of the disease were, with a single exception, all of the male sex. The inflammation does not so much attack the healthy, as those whose constitutions are originally weak, or have been debilitated through ill habits of living. It is far more serious than rheumatic pericarditis in its immediate consequences.

"Dr Ormerod informs us that 91·6 per cent. of his non-rheumatic cases were fatal; whilst of the rheumatic sort, 18 per cent. only were fatal. The local symptoms, again, of non-rheumatic pericarditis are at times very obscure—often, indeed, so obscure as not to direct the observer by any local signs to the seat of the disease; and thus it not frequently happens that the existence of the pericarditis is discovered only after death. As corroborative of this fact, it may be observed, that the local inflammation does not appear to exercise, by reaction (as happens in the case of rheumatic pericarditis), any particular influence over the patient's general condition, so as to appear in any direct way a cause of death.

"It is not, therefore, by the violence of the immediate effects of the local inflammation, that life is destroyed in cases of non-rheumatic pericarditis. Death rather results from the other effects of that particular disease which has, in fact, preceded, and given rise to, the pericarditis. Thus, for example, when pericarditis appears in the course of kidney disease, it usually supervenes at an advanced period of the renal disorder; but kidney disease (of the character here inferred) is, as we well know, for other reasons fatal in its consequence, and quite independent of its action upon the heart.

"Thus, then, in *non-rheumatic pericarditis*, the local inflammation plays a subordinate part. Its share, as a disturber of the system, is but small; so that it is, in fact, usually little more than a local sign (unimportant in its immediate effects) of a serious general disorder. In *rheumatic pericarditis*, on the other hand, the pericardital inflammation must be considered as the all-important fact; its consequences fall at once, and with violence, upon the heart, both impeding mechanically, and otherwise seriously deteriorating, its powers."

A word or two now about the treatment of Pericarditis, which affords us the key to our Author's views. He says:

"*Bleeding by venesection* in the treatment of pericarditis has been highly extolled; but at the present moment its practice is rarely resorted to. It is admitted by common consent that its value, as a remedial agent, has been overstated by Bouillaud, and other extreme admirers of the practice.

"A better pathology and truer method of observation have forced upon the physician, during the last few years, a conviction of the inutility and sometimes injurious effects of large venesections upon the progress of internal inflammations; and even they, happily few, who still follow the practice of former days, in the treatment of acute internal inflammations, admit that it is only during the very early periods of the pericardial inflammation, and in patients of strong and robust constitutions, that venesection is of service. That a moderate bleeding may be practised with impunity, *under such conditions*, there is little doubt; and that it often is of much benefit in giving temporary relief to the sufferings of the patient, and in relieving the congestion of the heart and lungs, is certainly true; but that such a bleeding has *any other beneficial effect or any direct influence over the progress of the inflammation has yet to be proved.*

"In considering the question of the value of venesection in pericarditis, we must remember:—That every inflammation is a disease of weakness, a condition which, in reference to health, is an asthenic condition; That heat, redness, and increased vascularity are no more signs of a sthenic circulation, than is the hyperæsthesia of a paralysed limb a sign of increased vigour of its nerve force; That rheumatic pericarditis occurs exceptionally only in persons of robust constitution; That an organ is involved in this inflammation, the constant performance of whose functions is indispensable to life; And that one of the most immediate effects of inflammation and its products is to introduce a paralysed condition of the muscular structure of the heart; That in pericarditis, the reaction of depression, consequent upon the excitement, is great, and sets in early; and that it is in those cases in which the inflammation appears most violent at the onset, that we are most cautiously to watch for and to expect the greatest amount of subsequent depression: that bleeding, moreover, will not arrest the exudation, but, on the contrary, in certain states of the body, will hasten and increase the amount of it; and that, inasmuch as endocarditis is very commonly associated with the pericarditis, bleeding, by promoting the tendency in the blood to the deposition of its fibrinous particles, will increase the danger of permanent injury to which the valves are exposed, through the deposition of fibrine upon them; and that venesection, as we well know, increases the amount of fibrine in the blood, and diminishes that of the red globules—the increase of the one and the diminution of the other being both indicative of weakness.

"Another special danger has been strongly pointed out by Dr Todd. (*Renal Diseases*, p. 412.) He says:

"'An active antiphlogistic treatment creates asthenia; asthenia gives to both rheumatic fever and gout what I may call *the shifting character*, which in both diseases is most perilous. When you find this shifting tendency, depend upon it that the asthenic condition of the patient is that which demands your earliest attention.' 'In this case of acute rheumatism,' he says again at p. 12, 'the loss of large quantities of blood from hæmaturia at an early period of the disease, has not sufficed to keep off a severe attack of pericarditis . . . nor has it saved the patient from swollen and exquisitely painful joints. On the contrary, the articular, as well as the cardiac symptoms, have been much less tractable than usual.'

"Experience has also shown us that venesection has no *directly* beneficial influence over pericarditis; and that large bleedings are prejudicial, and therefore inadmissible, in this disease. Nevertheless, that small bleedings are often of very great service *in relieving the congestions of the heart and lungs*, which so often arise as consequences of and coincidently with the pericarditis, is, I think, an undoubted fact. I have elsewhere spoken of this particular mode of action of venesection; and if the conclusions there arrived at are, as I firmly believe, correct, it necessarily follows that moderate venesection, practised for the object indicated, viz. to relieve the congestion of the heart and lungs, may be often resorted to with great benefit to the patient.

"In all stages of diseases of the heart in which congestion of the organ occurs, such venesection—duly adapted to the individual case—is of great service. I consider that I have even seen life preserved by timely abstraction of blood in cases of chronic valvular diseases of the heart, where the organ was so overwhelmed and labouring as to render death imminent."

Again, of mercury he remarks:

"*Mercury.*—The induction of specific effects of mercury was once considered essential in the cure of acute pericarditis, but the practice is now generally abandoned. Dr Taylor's observations first demonstrated its inutility. He showed, that of forty well-observed cases, only four improved after mercurial action was established; and there was no proof that in these four the improvement was other than a simple coincidence. Subsequent experience has fully confirmed Dr Taylor's opinion. The practice never seems to have been much resorted to on the Continent, and in Germany is untried and unknown. Gendrin's opinion, that mercury is completely useless in pericarditis, is the general opinion of his countrymen.

"Mercurial preparations, however, are undoubtedly of great service when used to regulate the secretions, which are always more or less disturbed during the progress of the inflammatory disorder."

The salts of potash are highly recommended

by Dr Markham in the treatment of this affection, than which, he says, there is no better remedy.

"When one or two scruples, according to the age of the patient, of the bicarbonate of potass, much diluted, are given every second hour, in cases of acute rheumatism, a marked amelioration of the symptoms is generally—though, I admit, not invariably—observed to follow its administration in the course of about twenty-four or thirty-six hours,—in fact, whenever the urine becomes alkaline.

"My own observation fully bears out the following statement of Dr Garrod, and the authority of many competent observers might be cited in support of it. 'Besides the influence on the duration of the articular affection which has been alluded to, I cannot help thinking that an effect is likewise produced on the cardiac disease, to a very considerable and important extent. In no case did the affection of the heart ensue after the patient had been more than forty-eight hours under the influence of the medicine; and it has appeared to me, that even when present on admission into the hospital, or coming on within a short period, its progress was powerfully checked by the treatment, and prevented from producing the terrible mischief which, when uncontrolled, it so frequently induces: this I should be inclined to ascribe to the altered condition of the blood, and especially of that portion giving rise to fibrinous deposits on the peri- or endocardium.' (Loc. cit.)

"Now, inasmuch as it is highly probable that the *materies morbi* which produces the rheumatic arthritis is identical with that which produces the rheumatic pericarditis, and as the potash treatment admittedly has a beneficial influence over the arthritis, we may reasonably conclude that the remedy will be also efficacious in preventing or arresting the progress of the pericarditic inflammation. Whether the potash acts by neutralising or eliminating the poisonous element, or whatever be its action, is a matter of secondary consideration."

Occasional doses of opium are also advised to tranquillise the nervous system; these are to be repeated as often as necessary to relieve pain. We pass over the intermediate chapters, and come to that on fatty degeneration. On this subject Dr Markham does not agree with Mr Canton in thinking the *arcus senilis* as pathognomonic of this form of cardiac disease. He observes:

"The existence of the '*arcus senilis*'—a fatty degeneration of the outer border of the cornea—was first pointed out by Mr Canton as a sign corroborative of the existence of fatty degeneration of the heart. There can be no doubt, however, that its value as a sign has been much overstated. The frequency with which the arcus senilis is met, in the most healthy individuals in advanced life, justifies us in considering it in them as little more than a natural consequence of old age. From a general review of the facts known on this subject, I am led to conclude that arcus senilis is, in old people, in the absence of other symptoms, a sign of little value as an indicator of fatty degeneration of the heart; but that when present in a marked degree, associated with other symptoms, it corroborates the diagnosis of the fatty degeneration: and that in early life it is much more frequently absent than present in cases of fatty degeneration of the heart."

Dr Markham considers that the hitherto obscure affection, angina pectoris, is attributable to fatty degeneration as its pathological cause. On this point he remarks:

"I have said that angina pectoris had been noticed by observers to exist in association with all the recognised abnormal states of the heart; and if we look into the history of the subject, we shall observe that it has been at various times ascribed by different writers to each one of those states. There was, however, one particular abnormal state of the heart—namely, calcification of its coronary arteries—which was found more frequently than any other to exist in connection with the symptoms of angina; and this diseased condition of the arteries was, consequently, considered by the majority of observers to be the cause of the angina. Now, it happens, as we have seen, that a very close relation is found to exist between calcification (or partial obstruction of the coronary arteries) and fatty degeneration of the muscular tissue of the heart, the latter condition being very frequently associated with the former, and apparently in some degree dependent upon it. The fatty degeneration has indeed been sometimes observed solely in that particular portion of the muscular tissue to which a calcified branch of the coronary artery was found to be distributed.

"*Symptoms.*—The connection of angina pectoris with this fatty condition of the heart, thus indicated by pathological anatomy, is likewise confirmed by the symptoms of the disorder. The paroxysms which occur in well-marked cases of fatty degeneration of the heart resemble those of angina pectoris. Sudden, violent, rending, oppressive, and even agonising pain at the epigastrium, extending more or less over the thorax, the pain passing down the arm and reaching even to the fingers; a weak and almost imperceptible pulse; hurried respiration and shortness of breath, approaching to choking and suffocation; pallor of the face, which is bedewed with perspiration, and expressive of extreme suffering, consciousness the while often remaining undisturbed; or occasionally syncope and coma, and even sudden death itself—these are all symptoms alike of fatty degeneration of the heart in its exquisite form, and of angina pectoris.

"And there are other points of resemblance between them. Both disorders are rare, comparatively speaking, in females; both occur chiefly in men, and at advanced periods of life; both may be associated with every kind of organic diseases of the heart. An attack, in both instances, is generally induced by excitement of the mind, or some unusual exertion of the body—that is to say, by causes which suddenly disturb and increase the heart's action; and for this reason, also, it occurs more commonly in the day than during the night. In both, during the intervals of the attacks, the patient seems tolerably free from disorder. In both, one attack is pretty surely, sooner or later, followed by another, and on each occasion it recurs at shorter intervals and with an increase of severity. Both have, sooner or later, one issue, and that a fatal one. The treatment required in both is alike: antispasmodics and diffusive stimuli during the attack; quietude of mind and body, nourishing diet, and careful regulation of the animal functions during the intervals. These facts, I think, inevitably lead us to the conclusion, that there is a close connection between the symptoms of the disease called angina and of fatty degeneration of the muscular structure of the heart."

We must now close our notice of this volume, which we can frankly recommend as a judicious and well-written treatise on the subject of heart-disease, and a safe handbook for reference in practice.

GENERAL CORRESPONDENCE.

MR PIGOTT'S PROPOSED NEW BILL.

To the Editor of the Medical Circular.

SIR,—In the last number of the 'British Medical Journal,' Mr Griffin, in announcing to the Poor-law Medical Officers the mode of remuneration for their services which he finally proposes to adopt in the forthcoming Poor-law Medical Reform Bill, says, "On trying a variety of modes of calculation, I find that the only one that works fairly is that now proposed, viz., 5s. per case up to the first 300 in number, above which 2s. per case only should be paid. In addition to this, a further sum, to be called mileage, is to be paid for all patients requiring to be visited at their own homes, &c." Notwithstanding the assumed *fairness* of this mode of remuneration in the above quotation, the mode will be found to work most *unfairly*, for the two following reasons: 1. It is founded on the principle of *more work, less pay*, which is intrinsically unjust to all. The time, medicine, and attention required for fifty cases of sickness are of equal monetary value, whether they be given by fifty separate Medical men or by one only. 2. It is *particularly* unjust to the Metropolitan men, because it is to them that the diminished rate of payment above 300 cases particularly applies; 377 being the highest average number attended by Provincial men, whereas 1,429 is the average number attended by Metropolitan men. From this it is seen how little the Provincial and how much the Metropolitan men will be affected by the diminished rate of payment above 300.

That portion of the above mode of payment called mileage is simply impracticable. With these objections before him, I hope that Mr Griffin will reconsider the matter before committing himself to a plan so replete with injustice. At the same time, I venture to point out the principles and conditions which appear to be essential in the determination of this difficult question, as follows:

1. The interests of the whole body of Poor-law Medical Officers, Provincial and Metropolitan, are identical; and, therefore, any mode of payment to be adopted should be based upon the principle of fairness and equality to all concerned.

2. But although their interests are the same, the circumstances under which they perform their duties are different; the difference consisting only in this—that the Provincial men have, comparatively, fewer cases, of greater severity in the aggregate, and distributed over a large space; whereas the Metropolitan men have, conversely, a very large number of cases, of less severity in the aggregate, and contained in a small space.

3. The conditions under which the Provincial men do their duties are such as to necessitate more expense of time and money than is required for similar duties in the Metropolis.

4. Therefore, the Provincial should be paid more per case than the Metropolitan Poor-law Medical Officer, in proportion to the difference of the foregoing conditions.

These data will, I think, be found to embrace the whole question. There may be great difference of opinion as to the amount which ought to be paid for each case of sickness throughout the kingdom. In reference to this, it need only be remarked that we can never expect to obtain a proper professional payment except by a universal "strike;" in the absence of which we must, therefore, endeavour to get what we are likely to have given us. But the relative proportion of payment to the Provincial and Metropolitan Poor-law Medical Officer, as determinable by the different circumstances affecting each, would appear to be contained in the sum per case of 3s. 6d. to the latter, and 5s. to the former.

It is for the consideration of the Poor-law Medical Officers whether this ratio of payment be a fair one, and whether, for the sake of its simplicity and the avoidance of the evils arising from several modes of payment, it would be acceptable to all parties. If so, I would beg to submit to Mr Griffin that the following clause would meet the case, viz.:

"That from and after the quarter-day next ensuing after the passing of this Act, the services of every Poor-law Medical Officer in England and Wales shall be paid for in the following manner; that is to say, in the Metropolitan Districts at the rate of not less than 3s. 6d. for every case of sickness, and in the extra Metropolitan Districts at the rate of not less than 5s. for every case of sickness."

By this, all that we ask is for the Law to step in, and, by determining a minimum rate of payment, to prevent the great injustice which the majority of us suffer, leaving those fortunate possessors of higher payment to remain in the enjoyment of the same. If this, together with clauses for permanence of appointment, an enlarged scale of extras, and greater facility to the poor for obtaining orders in the country, comprised the whole of Mr Griffin's Act of Parliament and became law, he would achieve as much as can be reasonably expected.

I am, &c., G. E. NICHOLAS.

4 Church row, Wandsworth, S.W.,
July 15, 1860.

MIDDLESEX HOSPITAL.—Dr Priestley has been appointed Lecturer on Midwifery at the School of the Middlesex Hospital. It is expected that he will shortly succeed Dr Frere as Physician-Accoucheur to the Hospital. We understand that no less than ten Physician-Accoucheurs, all of them of considerable eminence, competed for the Lectureship. Dr Priestley's appointment will end to a vacancy at the Samaritan Hospital.

HOSPITAL REPORTS.

GUY'S HOSPITAL.—July 10th, 1860.

Removal of part of a Fatty Tumour of Neck.—Mr Cock.

The patient, a strong-built, robust man, was singularly deformed by a diffused fatty tumour extending from the mesial line of the neck and chin, continuously half round the neck to the spine of the occipital bone, and cervical vertebræ posteriorly. The tumour had neither neck nor lobes to guide the division, but was extensively diffused. Mr Cock removed about one-fourth part from the posterior portion of the tumour, beginning at the back of the neck and extending the incision to a slightly indicated septum in the mastoidian region. It consisted of hardened or condensed fatty matter, had no capsule, and had to be detached with the knife from surrounding tissues. It manifested no malignant, but rapidly-increasing growth. Mr Cock did not think it would be advisable at a future time (if possible) to remove the remaining portion of this extensive tumour, which was not encysted, but continuous with the tissues and integument, and very condensed.

ST THOMAS'S HOSPITAL.—July 11th.

Lithotomy—Lateral Operation.—Mr Le Gros Clark.

The patient, a boy of fifteen years of age, showed the seam of a cicatrix in the perineum of a former operation performed in a provincial infirmary nine years since (we understood at Hull), which had not penetrated the bladder. From the site of the scar, it would have been impossible to have found the bladder, or to have penetrated it with safety. The father of the boy stated that another operation, performed at the same place and on the same day, had failed to reach the patient's bladder; to use the man's words, "they hadn't got into the bladder, and therefore didn't find a stone." The knife in this case had penetrated the integuments much below the proper site for the lateral operation, and must have been plunged under the tendon of the gracilis, amongst the large muscles, behind the tuberosity and ramus of the ischium, and was more likely to reach the recto-vesical region than the bladder.

The patient, a good subject and in good condition, suffered excessively from stricture of urethra and irritable bladder, the former of which, Mr Clark suspected, might have been produced by division of the urethra, or its having been injured or cut in the false operation referred to, performed nine years ago. Mr Clark attempted to pass the staff into the bladder before administration of chloroform, without success. The staff passed freely into the bladder, when the patient came under its full influence. He cut the integument, tissues, and into the urethra with one knife, when he changed it for a beaked knife with a convex edge. This beaked knife he guided into the staff with the index-finger of the left hand, carrying the beak through the membranous part of the urethra, behind the bulb, forward into the bladder, and returned it with a sweep the contrary way outward. This operation gives a free internal incision; being divided into two stages by the act of changing knives, it is necessarily more slow in performance. The axial line of the internal and external sections is tolerably parallel and good. It is a question if the internal section is not more free than the external in this operation—whether the unity of section is observed, the external incision corresponding with, and having the same degree of space and freedom with, the internal one, as is the case when the operation is continuously performed with one knife; and whether you do not secure, by section with one knife, a more easy introduction of forceps and extraction of stone. These are questions of some importance to be decided. In this case the stone was large, and Mr Clark found the bladder strongly contracted from its very irritable state. The forceps passed over it, and some little delay and difficulty, with a forcible traction, occurred in removing the stone. It was a rough mulberry crusted stone, with a phosphatic nucleus.

The value of chloroform was instanced in the want of success in passing the staff, in the preliminary examination before its administration, which was consequently productive of delay, and some avoidable suffering to the patient. The value of the straight staff is acknowledged as a great improvement. The art and science of Surgery is indebted to the skill of the instrument-maker for the only improvement since the day when Cheselden operated, more than a century past, in this hospital, for the lateral operation. The tradition of the gorget, upon which the beaked knife is a decided improvement, lingers at St Thomas's. Although the gorget is spoken of in connection with Cheselden's name and the lateral operation, it is very doubtful whether he used it—at any rate, after his success became confirmed; in short, it is affirmed that he did not. Cheselden's operations could scarcely have had the celerity recorded of them, if performed with a change of knives and the adjustment of the beak of a gorget in the urethra; namely, *fifty-four seconds*, in performance, on one occasion. At first Cheselden called the *lateral* the *direct* operation, which plainly expresses the mode and way he operated.

ST GEORGE'S HOSPITAL.—July 12th, 1860.

Amputation of Thigh for Diseased Knee-joint.—Mr Cæsar Hawkins. Necrosed Tibia after severe Compound Fracture—Free Incisions of Sinuses down to Bone, and trephining Bone.—Mr Cutler.

Amputation of Thigh—Disease of Knee-joint.

The patient, Annie Lawrie, a healthful-looking woman about twenty-five years of age, had been in hospital near upon eighteen months. The disease in the knee-joint commenced nine years since. She had latterly suffered great torture and excruciating pain, under which her health had failed. Mr Hawkins said this determined a resort to amputation, instead of treatment for excision of joint and anchylosis, which practice had been previously decided upon. Numerous sinuses had formed amongst the tissues communicating with the joint. The amputation was performed by circular incision in the usual manner, under influence of chloroform. Upon examination of the knee-joint after removal, the cartilages were gone, and the heads of the three bones found diseased, extensive degeneration and necrosis of bone having occurred. The absence of all suffering was singularly manifested in this case. The patient sang a Scotch air during the performance of the operation, in a manner she could scarcely have equalled under other circumstances.

Necrosed Tibia.

This patient is about fifty years of age; came into hospital with severe compound fracture of leg, and extensive injury. Abscesses formed, and disease of bone took place. Numerous sinuses indicated formation of matter deeply seated. Under influence of chloroform, a longitudinal incision was made upon the front of the tibia, from the superior sinus to the lowest, in extent about five inches down upon the necrosed bone. The diseased tissues and integument being dissected from the bone on each side, a trephine was applied over the diseased tibia twice, and pieces of bone removed on each occasion with forceps and elevator. No abscess in the bone was discovered by the trephine, or discharge of pus occurred. The usual water-dressings applied.

KING'S COLLEGE HOSPITAL.—July 11th.

Amputation of Breast—Prolapsus Uteri—Operation by Suture upon Fourchette of the Vulva.—Mr Fergusson. Varicose Veins—Acupressure, and Subcutaneous Section.—Mr Henry Lee.

Amputation of Breast.

The patient, a woman between thirty and forty years of age, was operated upon when under influence of chloroform for tumour of right breast. The nipple being a central point, a horizontal incision of an oval or oblong form was carried through the integument and tissues, dissecting away the tumour, which was free of adhesions, from fascia and muscles beneath. Scarcely any hæmorrhage occurred, and only one artery required to be secured. In speaking of this tumour, Mr Fergusson remarked that it had all the characters of malignant tumour—nipple retracted or drawn down below the level of the surface of the skin. On cutting into the tumour and pointing out a diseased cyst, which he divided, Mr Fergusson observed, this disease is what some have called encystic sarcoma: it is, as you see, a cyst of a distinct character, and is malignant; and where you find encysted cells with matter in them, there you have malignant disease. The skin and surface of the breast were little altered or diseased, and no puckering, except at the nipple, was manifested. Mr Fergusson had watched the case some time, and had recommended an operation, which he was sorry was disregarded, as the chances of success were now doubtful.

Prolapsus Uteri.

The patient, a middle aged-woman, had been under Mr Fergusson's eye for some years, and he had performed an operation on a former occasion. On that occasion the bladder, with the posterior wall of the vagina, prolapsed; on the present occasion the vagina and uterus prolapsed. Under the influence of chloroform, a portion was cut from the margin of the posterior commissures of the vulva, and for more than an inch—about an inch and a half—on the sides, when needles and silk sutures were applied as for hare-lip, the edges of the cut surface brought nicely in apposition, and water-dressings applied. Mr Fergusson explained that in this operation he used the common silk ligature, not metallic. Having, he said, during a lengthened practice used as many metallic sutures as most, he found the old silk ligatures were best. He said it was all very well for gentlemen to talk about what they do not practise, and consequently do not understand; they talk and write, but know nothing of surgery. This, we believe, is the first announcement of secession from the recently-introduced practice of metallic wire ligatures, to return again to silk, and we shall probably hear more of objections to their use.

Varicose Veins.

Mr H. Lee operated upon a powerfully-built man for varicose veins on the right leg. He operated upon two veins upon the anterior aspect of the leg, at the anterior part of the upper third. He introduced two metallic steel needles under each vein, leaving a space of about half an inch between them; he then made a subcutaneous section of the vein. He stated that this patient came from the Sailors' Home at Tower hill, from which place many cases were constantly sent to King's College Hospital. In two or three days after their admission they were operated upon, and discharged cured in ten days. In this way King's College had been able to give a body of serviceable recruits to her Majesty's navy of no inconsiderable amount—to say nothing *of volunteers*. Mr Lee referred to the various modes of treatment of varicose veins. That of formation of clot, he said, answered very well for a time; then soft fibrine became generated, inducing abscess of the coats of the veins. Soft fibrine might become absorbed, and no more deadly poison than it could be received into the system. Or matter might form, when incisions would be required, and a troublesome and tedious cure result. Pressure was another mode. Many years ago Mr (now Sir Benjamin) Brodie recommended and practised subcutaneous section, but not accompanied with *acupressure*. The advantage of this operation is, there is no external wound, and the acupressure induces sufficient adhesive inflammation to cause the internal coats of the veins to throw out fibrous lymph, which completes the obliteration of the vessel.

Formation of Bone.

Dr Ollier of Lyons being present, Mr Bowman introduced him, and exhibited specimens of the experiments he had made to demonstrate the formative force of the function of the periosteum in the production and growth of bone, and which had been recently brought before the British Association at Oxford. A piece of tibia and fibula had been sawn away from the leg of a rabbit, and a portion of periosteum from another animal having been transposed to the part, and become attached to the denuded bone, laminæ of new bone became deposited in a state of incipient or imperfect ossification. Another experiment of a similar kind showed, after a longer period, considerable growth of the bone—in short, to its complete restoration. In another experiment a portion of the skin of the head and neck, including the ears, was dissected from a large portion of the occipital region of another rabbit, and transposition upon it of periosteum, in which the formation and growth of a lamina of new bone was demonstrated, and the parts being injected, the vascular communication was beautifully manifested. In another experiment the tibia of a rabbit was exhibited, from the upper part of which the periosteum had been denuded, and

folded down over the lower, and wrapped round the leg, showed a rim or collar of new bone formed round it. Again, a portion of periosteum, placed upon a living surface, showed first the formation and growth of a cylinder of bone without medullary cells, or cancelli yet produced. The same experiment in another part showed a cylinder of bone with both medullary cells, and cancelli perfectly formed after a longer period. The ossific secretion is produced in a line with the periosteum.

Mr Bowman made a few remarks upon these interesting experiments, which, he said, clearly and completely established the formative force inherent in periosteum to secrete and promote the growth of bone. He said this had been announced and promulgated some years back by Professor Sharpey and others, and nine years ago he himself had maintained this doctrine in his physiological lectures at King's College; but its establishment is completely confirmed by these interesting experiments of Dr Ollier. We believe Professor Syme, many years since, demonstrated this physiological fact at Edinburgh.

BRITISH ASSOCIATION AT OXFORD.

THE DARWIN THEORY OF SPECIES.

Two papers on Saturday, the 30th ult., were of great importance to Medical men, as bringing under debate a subject on which their opinion and advice of late have been often sought in mixed society—viz., as to what they think of Mr Darwin's book? One was a communication by a Dr COLLINGWOOD 'On Recurrent Animal Form and its Significance in Systematic Zoology.' The object of this paper was to call attention to the frequent recurrence of similar anatomical forms in widely-separated groups of the animal kingdom. The Author thought that no principle of gradation would sufficiently account for these analogies, but that deviation from typical form is usually accompanied by modifications of typical habits; and the somewhat dubious principle was supported, that agreement of habit and economy in widely-separated groups is always accompanied by similarity of form. The appearance, in fact, of the Physiological Section during the reading of this and the following paper, the crowds collected for some purpose, told that there was something "in the wind"—some subject of considerable interest to the Profession at large about to be discussed.

The other paper was by Dr DRAPER, of New York, 'On the Views of Mr Darwin and others on Development of Intellect and Progression of Organisms.' This communication, rather American in its peculiarities of diction, was only of importance as eliciting a most remarkable but most conflicting discussion, in which Sir B. Brodie, the Bishop of Oxford, Professor Huxley, Dr Lionel Beale, Mr Lubbock, Professor Hooker, and others joined, as to origin of "Species." The object of the paper of Dr Draper was to show that the advancement of man in civilisation does not occur in a fortuitous manner, but is determined by law. "In three great lines of life," Dr Draper established that "the general principle is to differentiate instinct from automatism, and then to differentiate intelligence from instinct;" that it is impossible also to separate the individual from the race, and what holds good for the one holds good for the other; man, too, being the archetype of society.

The discussion commenced by the Rev. Mr CRESSWELL, who denied that any parallel could be drawn between the intellectual progress of man as this archetype, and the physical development of the lower animals. The Americans are wrong, totally wrong, as to the 'Iliad' of Homer, to wit, being produced when Greece was perfect as a nation; it was produced during the babyhood or infancy of Greece.

Sir B. BRODIE, in a long and masterly exposition of the subject of Mr Darwin's book, stated that he could not subscribe to its hypothesis. The "primordial germ" in this hypothesis has not been demonstrated to have existed. The great thing, Sir Benjamin believes, which separates man from the lower animals, is a power of self-consciousness — "self-responsibility," as termed by some writers—(Dr Kidd)—consciousness. This principle differs from anything found in the material world, and it is difficult to see how this could originate in lower organisms. This, in fact, is identical with Divine Intelligence; and to suppose it could originate with matter, as held by Mr Darwin, involved the absurdity of supposing Divine Power to be dependant on anatomical and other arrangements of matter.

The Bishop of OXFORD also attacked the Darwinian theory at considerable length. Medical men must know, if they were properly instructed or at all on a level with general knowledge in physiology, that even the remains found in Egyptian catacombs all speak of their identity with existing physiological forms. The Rev. Prelate entirely agreed with the masterly arguments of Sir B. Brodie, even in the great case of the pigeons of Mr Darwin, which were altered physiologically by training, so forcibly urged even in medical journals as conclusive. It proved nothing at all; the thing was ridiculous, for no sooner were these animals set free than they returned to their primitive fixed type. Everywhere sterility attended interference with species, well seen in the closely-allied forms of the ass and horse. Medical men ought to teach and preach these things, for the greatest names in science are opposed to Mr Darwin's theory.

Professor HUXLEY agreed, on the contrary, that the Darwin theory, if not strictly true, is the best explanation of the origin of species which has ever yet been published. The question is not so much as to transmutation or development of species, as production of forms which become permanent: thus the short-legged sheep of America, like the new pigeons, originated in the birth of an original parent of that stock, still kept up, with short legs. This single fact is at the bottom of the whole subject.

Dr LIONEL BEALE referred to some of the difficulties of the Darwin hypothesis, more especially those vital tendencies of allied species which now seem to be independent of external agencies. He spoke of the unnecessary "verboseness" of Darwin's book.

Mr FITZROY denied Professor Huxley's statements; but Mr LUBBOCK accepted them, and thought Professor Huxley right.

Professor HOOKER being called upon by the President, went over the subject with considerable ability, and showed that the Bishop of Oxford misunderstood the gist of Mr Darwin's book, which is in fact a strong protest against the anatomical transmutation of species. Mr Darwin holds the doctrine of the successive development of species by variation and natural selection. Dr Hooker's experiences of the vegetable would lead him to agree with the Darwin hypothesis. One-half of the known kinds of plants are disposable in groups, the species (1) connected by various characters common to all in that group; in fact, the general characteristics of orders, genera, and species amongst plants afford the strongest countenance to Mr Darwin's hypothesis. After a further elucidation of the subject as bearing on the views of Edward Forbes of the unchangeability of species, also liable to discussion, Professor Hooker said he had no hesitation in publicly taking up or adopting the Darwin hypothesis. He would lay it down, however, should a better one be forthcoming, or should the now-abandoned doctrine of original creation of species regain all it had lost in his experience. [Professor Hooker's views seem to have rather staggered the preceding speakers.]

Dr DAUBENY at a former meeting having brought under notice the final causes of sexuality in plants as bearing on Mr Darwin's work, one use, he thinks, is the dissemination of species; for many plants, if propagated by buds alone (as they may be so propagated) would in a manner be confined to a single spot. Flowers have been provided, too, probably in order to prevent that confusion that would arise from the uniformity in the aspect of the vegetable kingdom if plants had been exclusively multiplied by buds; in fact, a bud is a mere counterpart of the stock from whence it springs, so that we are always sure of obtaining the very same description of fruit by merely grafting a bud on another plant of the same species—more so, in fact, than by the use of seeds: so much is this the case, that by the latter some variations from the primitive type are sure to result. Dr Daubeny gave his assent to the Darwin hypothesis so far as the origin of species by natural selection is borne out by the final causes of sexuality in plants: he did not at all advocate it to the extent, however, Mr Darwin himself did.

Dr WRIGHT, as a curious instance of *quasi* reason in a gorilla, mentioned how near it came to man in one instance he had known,—the female gorilla to go of itself to the sea-shore, taking its young with it, and feeding it on shell-fish and oysters, which they take with great facility!

Professor OWEN, whilst giving all praise to Mr Darwin for the courage with which he had put forth his theory, felt still it must be tested by induction from facts by the Bacon method: as a contribution to these facts, he would refer to the structure of the gorilla, whose brain presented more differences as compared to the brain of man, than it did when compared with the brains of the most problematical form of quadrumanous animal. The deficiencies in the cerebral structure between the gorilla and man are immense: the posterior lobes in man's brain present parts wholly absent in the gorilla; the same is seen in the other parts of the body. The great toe also in man is intended that he shall stand erect, whilst in the lower monkeys this is impossible, and they must always walk on "all-fours" or climb.

Professor HUXLEY denied altogether Professor Owen's statements as to the brain of the gorilla, and appealed to Tiedmann's dissections. He maintained also that there is more difference between the monkeys without big toe and the gorilla, than there is in this respect between the latter and man. The gift of speech, he thought, is the great feature, and distinguishes man from the gorilla.

The debate, we may say, finally concluded leaving everything very much as it found it; Professor Owen and the party of dissent being very much like a still more recent party, who say, "We defer all to a matter of feeling, though inclined to assent to the argument."

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 26, 1860.

F. C SKEY, Esq., President, in the Chair.

A paper by Mr J. W. HULKE was read, on

GLAUCOMA AND ITS SURGICAL TREATMENT.

The Author refers to a paper 'On the Morbid Anatomy and Pathology of Glaucoma,' communicated by him to the Society in December, 1857. Since then, the treatment of glaucoma by 'iridectomy' has been extensively practised in the Royal London Ophthalmic Hospital and in private, and the results have been so very successful that the Author is desirous of bringing the operation under the notice of the Society. In order to prevent any misunderstanding respecting the nature of the cases in which he advocates the performance of iridectomy, Mr Hulke gives an outline of the symptoms, the ophthalmoscopic signs, and the morbid anatomy of glaucoma. There are two forms of this disease—an acute and a chronic; but many cases have an intermediate character. In 75 per cent. or more of all cases, the active stage is preceded by a premonitory period—'prodroma.' In acute cases the transition is abrupt; in chronic cases it takes place by insensible gradations.

Premonitory Symptoms. — Rapidly-increasing presbyopia; the appearance of a coloured halo round the flame of a candle; the spontaneous appearance of flashes and other spectra. Intercurrent obscuration of vision, attended with vague orbital and frontal pains, slight hardness of the eyeball, and contraction of the field of vision. The pupil is large and sluggish; the size of the anterior chamber is much diminished. The duration and intensity of these symptoms are very variable, but they are rarely absent.

Acute Glaucoma.—The active stage sets in as sudden and violent outbreak, often at night. Violent racking pain in the eyeball, often attended with sickness, and followed by rapid extinction of sight. The pupil is widely dilated and motionless; and the lens has sometimes the peculiar greenish tint which was formerly considered so characteristic. The ciliary vessels are swollen; the conjunctiva is red and often chemosed; the globe is very hard; the cornea is dull, and its sensibility is lowered. Remissions

are followed by fresh paroxysms, and complete irremediable blindness always ensues.

Chronic Glaucoma.—The premonitory period slowly glides into the active. The obscurations, which were at first evanescent and separated by long intervals, become more frequent, and last longer. The contraction of the visual field progresses. The tension of the globe increases. The iris becomes dull; the aqueous humour turbid; the cornea dimmed and flattened. Mr Hulke lays stress on the flattening of the cornea, which is easily demonstrated, because it has been recently stated that the cornea becomes conical in glaucoma.

Ophthalmoscopic Signs.—Excavation of the optic nerve entrance, and pulsation of the retinal vessels. To these capillary apoplexy of the retina is often added; and sometimes there are small blood-clots in the vitreous humour, which is unnaturally firm. It is only late in the disease, when all the component structures are undergoing atrophy, that the vitreous humour becomes fluid.

The Nature and Causes of the Glaucomatous Process.—All the leading features of the glaucoma are due to excessive tension of the eyeball from a superabundance of fluid within it, which distends the vitreous humour. This fluid—serum—is derived mainly from the choroid. Many circumstances show that the retina is only passively concerned. Glaucoma might be considered a serous choroiditis. Mr Hancock has advanced the theory that spasm of the ciliary muscle forms an essential part of glaucoma. The Author has, however, found complete atrophy of this muscle in dissections of glaucomatous eyes; hence the inference that this muscle is concerned in maintaining the glaucomatous condition. The Author has been unable to trace any connection between glaucoma and gout or rheumatism. Some other diseases and injuries of the eyeball occasionally assume a glaucomatous type. This is especially the case with wounds of ciliary region and sclerotico-choroidal staphyloma.

Treatment.—Generally the age and broken health of the subjects of glaucoma forbid antiphlogistics; venesection is inadmissible; leeches and counter-irritants are useful as adjuncts, but cannot alone cope with the disease. The excessive tension of the globe is suggestive of the evacuation of some of the superabundant fluid by tapping. The old surgeons, Antonius, Nerck, Jobus à Meckren, and others, were familiar with this operation, but they practised it chiefly in hypopion, onyx, and hydrophthalmos. Wardrop ('Med.-Chir. Trans.,' 1813) tried it extensively. With a view to lessen fulness and congestion, he tapped the anterior chamber in superficial and deep-seated inflammations of the eye. The operation was at first warmly taken up by other surgeons, but soon fell into disuse. In our own day it has been strongly advocated by Desmarres, but it has found little favour with English surgeons, though most have occasionally performed it. In glaucoma the relief that paracentesis corneæ affords is too transient to render it of much value. Paracentesis scleroticæ has been practised by Desmarres and Hancock in glaucoma, though with different objects. Mr Hulke reverts to this, after fully describing the operation of iridectomy as proposed by Dr A. von Graefe.

Iridectomy consists in excising a segment of the iris, in its whole breadth, from the pupillary margin outwards to its insertion. This is effected through an opening of corresponding size at the extreme edge of the anterior chamber. Iridectomy may be practised at any part of the iris. Graefe usually makes it outwards; but adds that, when desirable for the sake of appearance, it may be made upwards. This latter position has been adopted by Mr Bowman, and is that which Mr Hulke has generally chosen. By removing the iris in this manner, the pupil is at once enlarged up to the corneal incision, which forms, as it were, the base of a coloboma iridis, and the edge of the lens, with the suspensory ligament, stretching in front of the vitreous humour and the ciliary processes, are exposed to view. The little blood which oozes into the anterior chamber from the cut edges or surface of the iris should be at once pressed out or removed with a scoop. The after-treatment is very simple. A light compress may be applied for a short time as a precaution against hæmorrhage. This may be replaced after an hour or two by a piece of wet rag. The room should be shaded. Usually nothing else is necessary. At first the aqueous humour trickles away; but the corneal wound soon heals, and the anterior chamber fills again. The hardness of the eyeball is at once lessened, and a natural tension is gradually attained; the pain abates, and soon altogether disappears. As regards vision, the ultimate results are intimately dependent on the period at which the iridectomy is performed, being more perfect where it has been early undertaken than where it has been postponed. In the premonitory period, where the symptoms are well marked, the propriety of operating cannot be doubted. In acute glaucoma, where the operation is done during the first inflammatory attack, or soon afterwards, vision is very completely restored. In chronic glaucoma, the results are less uniform and less decided. This is in consequence of the insidious nature of the disease—structural changes of the retina creeping on *pari passu* with the gradually-increasing tension.

Alleged Objections to Iridectomy.—1. Its reported uniform failure in the hands of some surgeons. This is in great probability to be generally attributed to its having been practised in cases which were not true instances of this disease. Many failures have proceeded from its having been done at far too late a period. 2. The great difficulty of the operation. This has been much magnified. It does not require more skill than most surgeons possess, and when chloroform is used it becomes really a simple matter; but even were it difficult, which it is not, in the absence of other known means of cure, we should be no more justified in rejecting it on this account, than we should be in refusing a patient the benefit of herniotomy where the taxis and other measures had failed. 3. The disfigurement produced by the coloboma iridis is so slight that it cannot constitute a real objection. 4. Its supposed injurious action on accommodation. Further experience has corrected some misimpression which at first prevailed respecting its influence on the adjustment of the eye. The previously existing presbyopia is not increased by removal of a portion of the iris; indeed, the refracting power of the globe sometimes actually increases after iridectomy—probably, as Graefe has shown, in consequence of the flattened cornea resuming its natural curvature. To avoid these alleged disadvantages, paracentesis scleroticæ has been advocated by Middlemore, Desmarres, and Hancock, as a substitute for iridectomy. Middlemore proposed to evacuate the turbid, diffluent, vitreous humour with a grooved needle, and to replace it with a syringeful of clear water. But, except in very old cases, the vitreous humour is much too firm to flow out along a grooved needle; and probably few English surgeons would adopt Desmarres' suggestion, of introducing a probe and breaking it up. Mr Hancock, considering a spasm of the ciliary muscle to be an essential part of glaucoma, divides this muscle by striking a knife through the ciliary region backwards and inwards towards the axis of the globe. But Mr Hulke has demonstrated, by microscopical examination, advanced atrophy of this muscle in many glaucomatous eyeballs; whence it follows that the ciliary muscle is not actively concerned in maintaining the glaucomatous process. In all probability, the success of Mr Hancock's operation is solely due to the draining away of some of the superabundant fluid. According to this view, it is simply a peculiar mode of paracentesis, and cannot rank as a substitute for iridectomy until it has been thoroughly established that it permanently relieves excessive intra-ocular tension, which, in common with most surgeons, Mr Hulke has found that tapping the vitreous humour fails to do.

THE INTERNATIONAL STATISTICAL CONGRESS.

This Congress was opened on Monday, Prince Albert delivering the inaugural address.

On Tuesday morning the various Sections of the Congress met at King's College, at ten o'clock. The first section (Judicial Statistics) was presided over by Lord Brougham, the second (Sanitary Statistics) by the Earl of Shaftesbury, the third (Industrial Statistics) by Sir Roderick Murchison, the fourth (Commercial Statistics) by Nassau W. Senior, Esq.; the fifth (Census Statistics) by Earl Stanhope, and the sixth (upon Statistical Methods) by Professor Graham.

SECOND SECTION.—SANITARY STATISTICS.

The Section met on Tuesday, at ten o'clock, the Earl of Shaftesbury in the chair.

A paper, by Miss Nightingale, was read, "On the Method of Reporting Hospital Statistics." The proposals were thirteen in number, and referred to the following matters:—Separating the record of "cases of disease" in Hospital from the "persons" treated. The adoption of a uniform system of record of transfer of patients from the Medical to the Surgical side of an Hospital, and *vice versâ*. Registering the date of attack as well as the date of admission of the patient. Weekly or monthly record of admissions, as well as annual summaries. The adoption of a system of registration for out-patients of Hospitals and Dispensaries. Recording the locality whence patients are received. Recording secondary diseases arising in Hospital, and registering the deaths from secondary diseases, as well as from diseases for which the patients were admitted. The proportion of empty beds for the whole year, and for each season. The cost of each in and out-patient, given under different heads. In Hospitals supported by voluntary contributions, the number of in and out patients, and also the number of letters of recommendation given. This paper was discussed on Wednesday, when two of the propositions were withdrawn, as being better expressed in others. All the others were adopted, except that referring to the registration of deaths from secondary diseases, which was withdrawn for future consideration.

The consideration of Dr Sutherland's paper on a "Uniform Scheme of Sanitary Statistics," was resumed. The propositions were discussed, and adopted, with several additions and modifications, excepting Nos. 14 and 15, the discussion on which was adjourned.

An important paper, by Dr Farr, was read on Thursday.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

VACCINE BOARD.

Mr Brady asked whether it was the intention of the Government to institute a Vaccine Board in Dublin similar to that which exists in London. He also asked the Chief Secretary for Ireland if his intention had been directed to the fact that the Board of the Cock-Pock Institution of Dublin charges 2s. 6d. for two ivory charged points of vaccine lymph to medical men, while the said Board receives an annual grant of 400*l.* for the better supply of pure lymph for the protection of the people.

Mr Cardwell was understood to say that he had caused inquiries to be made into the subject to which the hon. gentleman referred, but their result had not yet reached him.

DR GUYDIR.

Colonel Greville asked the Judge-Advocate whether it was true that Dr Guydir, Assistant-Surgeon, Royal Longford Rifles, who was tried by a general court-martial on the 1st and 2nd days of June last, was placed in arrest on the 10th day of May last, and still remained under arrest, and debarred from practising his profession, in consequence of the finding of the Court not having yet been promulgated by the authorities; and if it was true that six field officers and seven captains of disembodied regiments of Militia were still kept under daily pay and allowances, awaiting the promulgation of the sentence upon Dr Guydir.

Mr Headlam said that some delay had necessarily arisen after Dr Guydir was placed under arrest, before the court-martial could be summoned to afford the means of making the necessary inquiries and forwarding the facts of the case to the Judge-Advocate. After the finding of the Court he had two audiences of her Majesty on the subject, and it was not until the third audience, on June 22, that the sentence was confirmed. On the following day it was sent to the Commander-in-Chief, and he was happy to say the result was that Dr Guydir would be released. The only inconveniences the officers composing the Court were subject to, were to hold themselves liable to be called upon to reconsider the facts.

ADULTERATION OF FOOD AND DRINK BILL.

The Lords' amendments to this Bill were agreed to.

OUR NOTE BOOK.

INVESTIGATIONS CONCERNING HYDROPHOBIA.

From a series of returns made upon this subject, from different departments in France, during several years, and epitomised by Dr Tardieu, in the 'Annales d'Hygiène Publique,' we glean some interesting information upon the following points:

I. *The species of animal by which the Hydrophobia was communicated.*—Out of a total of 228 cases in which reference was made to this point, 188 were stated to have been produced by the bite of a dog, 13 by that of a cat, 26 of a wolf, and 1 by the bite of a fox. In two cases in which the bite of a cat produced the disease, one animal is reported to have become rabid in consequence of an extensive burn, another owing to its having been robbed of its young. These cases are of considerable interest, as they tend to resolve the still doubtful question of the spontaneous development of Hydrophobia in other species of animals than the canine.

II. *The season of the year at which this disorder is most frequently developed.*—This circumstance was noted in 181 cases, 110 of which occurred during the hot seasons of the year, 71 only during the cold. There is, doubtless, a marked difference in favour of the months in which the temperature is most elevated; but it does not remain a less constant fact that no season is really opposed to the development of Hydrophobia, or can render its effect less formidable.

III. *The average number of persons who escaped the malady after being bitten.*—On this point we have the records of 198 cases of persons who were bitten, in many instances by the same animal; of these, 112 were subsequently seized with Hydrophobia, whilst the remaining 86 experienced no ill effects. We need scarcely remark that numerous adventitious circumstances, such as the interposition of an article of clothing to which the saliva of the rabid animal might adhere, the state of the patient's mind or health after the injury, &c., would considerably influence the results in this particular.

IV. *The length of the stage of Incubation.*—In a large majority of cases this was not more than a few weeks. Out of 147 cases referred to, the period of incubation was under a month in 26, more than a month but under three months in 93 cases, whilst in the remainder the length of time occupied was from six to twelve months. The incubatory period appeared shorter in very young persons than at any other age.

V. *The length of time between the development of the disease and its fatal termination.*—On this point the statistics collected corroborate too fully the preconceived ideas as to the rapid progress of the disorder. Out of 161 cases, death put an end, within a week, to the horrible sufferings of the patients in 158, more than one-half of that number dying within four days, even, from the time at which the malady first manifested itself.

VI. *The relative efficacy of the means employed to prevent the development of Hydrophobia.*—Upon this all-important portion of the subject Dr Tardieu observes that the fact cannot be too strongly insisted upon, that the only hopes of security from the fatal effects of this dreadful disease consist in immediate cauterisation with the red-hot iron, and that every other method only comprises the future safety of the patient by the irreparable loss of the only moments during which the preventive treatment is applicable.

VII. *Curative treatment of Hydrophobia when it has become developed.*—Dr Tardieu makes the disheartening statement, that of all the remedies which have as yet been suggested, chloroform included, for the treatment of Hydrophobia when fully developed, he has found none to have been attended with sufficiently promising results to enable him definitely to say that it will effect a cure.—'The London Medical Review.'

A NEW SYSTEM OF BATHING.

We borrow from the Transactions of the Academy of Medicine, some very curious details relative to a hydraulic apparatus which threatens the old system of baths with utter revolution.

We noticed in this Journal (Art. 5622) that one of our honourable contemporaries of the Press, Dr. Sales-Girons, had succeeded in reducing water to spray, and in introducing it in this condition into the respiratory organs, each of its spherical molecules containing all the volatile and fixed elements of the integral from which it was detached, and in the same proportions. This important peculiarity, now demonstrated, is sufficient to establish a clear distinction between the respiration-rooms of the ancients and those instituted in 1856, on the new principle, inaugurated by M. Sales-Girons. In the former, the pulmonary mucous membrane was brought into contact with the *gaseous principles* only of mineral waters, to the exclusion of the *fixed ingredients;* in the latter, it is the *entire* water which is conveyed into the respiratory organs, in the same way as on the seashore, the water, reduced to spray by the wind, and closely mingled with the atmosphere, is directly inhaled by the patients. We have not to consider here the breathing-rooms, to the utility of which we have called attention, nor even the more or less ingenious portative apparatus, with which M. Sales-Girons and M. Mathieu, surgical instrument-maker, have endowed therapeutics. We are merely desirous of bringing to the notice of practitioners an equally ingenious derivation of of M. Sales-Girons' felicitous idea, realizing on a larger scale the advantages of the reduction of water to spray. We refer to the *hydrofère* bath, devised by M. Mathieu (de la Drôme).

Formerly a representative of the people, M. Mathieu is no less known by his meteorological studies than by the honourable position he acquired in our political assemblies. M. Mathieu, of an ardent and investigating mind, does not confine himself to the introduction of a few drops of mineral water into the respiratory organs. M. Gavarret, in a concise and elegant report, recently informed the Academy that M. Mathieu replaces the sixty or eighty gallons of water, containing an ordinary bath, by six or eight pints of liquid comminuted by his *hydrofère*. M. Mathieu rightly thought that in a bath of stagnant water, the portion of liquid in immediate contact with the skin alone, exercises a topical action, and supplies materials for absorption. This being admitted, he sought to keep up on the surface of the skin a very thin layer, constantly renewed, of active liquid. The apparatus invented to solve this problem is very simple, and operates with perfect regularity.

The liquid, enclosed in a copper box, is divided into very fine particles by a current of air supplied by a fan, working under a pressure of about two inches of mercury. The subject seated in a bathing-box similar to that used for fumigations, the jet of gas and of comminuted liquid escapes by a discharge-hole situate on a level with the knees, rises obliquely, spreads, and is broken into an excessively thin rain, which is incessantly thrown upward on the body of the patient. The head may, at pleasure, be kept outside the box, or remain exposed to the action of the rain, the temperature of which may be regulated according to the peculiar indications of each case.

Frequent experiments, instituted in M. Hardy's wards at the Hôpital Saint-Louis in Paris, admit of the affirmation, that with M. Mathieu's system of bathing by affusion, baths into which enter high-priced substances, such as iodine, mercury, or aromatic essences, may be administered *at a very trifling cost.* With the *hydrofère* the medical practitioner may, at all places and in all seasons, subject his patients to the influence of sea-water or natural mineral water baths; for M. Hardy's experiments peremptorily establish, and that was the principal question, that the physiological and therapeutic action of the hydrofere baths is identical with that of the mixtures or solutions used in the ordinary baths. One advantage more which M. Hardy points out in the hydrofere baths is, that the water, being constantly renewed, more easily carries away with it the scales and foreign matter adhering to the surface of the skin. A great number of persons labouring under grave, and for the most part stubborn affections, have been radically cured or much relieved by the hydrofere medicinal baths. In the treatment of those diseases of the skin especially which extend to the face and scalp, the superiority of these baths is incontestable. The experiments conducted at the Hôpital Saint-Louis prove that patients, far from desiring to keep their heads outside the box, generally prefer exposing it, like the rest of the body, to the action of the spray.

If this latter advantage be confirmed by subsequent observation, it will plead powerfully in favour of the *hydrofère.* We are not surprised to learn that the Administration of Public Assistance has required a special and detailed report on the subject. The Academy has taken the requisite measures for the accomplishment of this necessary formality. From these circumstances, it may be fairly inferred that M. Mathieu's system, which is so economical, will soon be in general use, and realise one of the most desirable and the least foreseen improvements of balneatory medication.—'Journal of Practical Medicine and Surgery.'

GLYCEROLE OF LEAD.

The following is suggested as a substitute for Goulard's cerate. This cerate, as is well known, becomes speedily rancid, and in that state is more irritating than soothing to inflamed surfaces. The substitute does not change, is easily washed off with water, and can be reduced to any desired extent, for the purposes of a wash, with rose or distilled water:—

Pure glycerine, ...	13½ oz. (fluid).
Solution of sub-acetate of lead, .	2½ oz. "
Camphor, ...	1 dram.

Triturate the camphor into powder, with a few drops of alcohol; add the glycerine; heat in a water-bath until the camphor is dissolved; when cool, add the solution of lead, and shake well together. These proportions are those for Goulard's cerate, substituting glycerine for the oil and wax.—'Journal and Transactions of the Maryland College of Pharmacy,' and 'British American Journal.'

LEGAL INTELLIGENCE.

OXFORD CIRCUIT.—Oxford, July 14.

Civil Court.—(Before Mr Justice Hill and a Special Jury.)

GARDNER *v.* HARRAP.

Mr Serjeant Pigott and Mr Gray appeared for the plaintiff; Mr Huddleston, Q.C., and Mr Phipson, for the defendant.

The plaintiff in this action, Henry Gardner, was a farmer at Chipping Norton, Oxford, and hef sued the defendant, Henry Harrap, a sort o surgical practitioner of great repute at Brighton, to recover damages for negligent and unskilful practice as a surgeon in treating the plaintiff for the cure of a bad knee.

It appeared from the plaintiff's evidence that in the year 1857 he had taken a cold, which brought on a rheumatic attack in his knee. The joint was inflamed, and he was confined to his bed for several weeks, and, as the result, the knee became contracted. Under the advice of his medical attendant, Mr Farwell, he went to Bath, and remained there for several weeks, under the care of a Mr Wood, a surgeon, who advised rubbing the knee. On the 11th of October, 1857, he left Bath in improved health, and returned to Chipping Norton, where, under Mr Farwell's directions, the knee was rubbed every day for two hours. On the 18th of December he went to Brighton, and consulted the defendant on his stiff joint. The defendant was an irregular practitioner, but he had a great reputation and large practice. He assured the plaintiff that there was no disease in the knee, but the joint was drawn up in consequence of very improper treatment. The defendant rubbed in some white ointment, and then put on some large plasters, which covered the limb from above the knee to as low as the ankle. The plaintiff told the defendant he thought he must have come to the wrong man, as he expected to be shampooed; but the defendant said there was no mistake, as he was the only Harrap in Brighton, and he was a spinal surgeon. He said he could cure him in six weeks, as he had no disease in the joint. Upon this the plaintiff put himself under the defendant's care and treatment. The treatment consisted in the application of a strong lotion laid on wet cloths, which the defendant called putting the leg "in pickle." The lotion was very strong, and smelt like ammonia, and caused the plaintiff great pain and inflammation in the leg. The plaintiff complained of this to the defendant, but he consoled him by telling him that he could not expect to be cured without going through a considerable degree of pain. However, he put on a milder lotion, and substituted a milder plaster—viz., a lemon-coloured plaster for one of orange colour. Matters went on thus till February 1858, when some reference was made to payment at the rate of

2*l.* for three visits; but the defendant told the plaintiff that he had never charged him anything, neither would he till he cured him. In the month of April, 1858, the plaintiff had taken cold and felt very ill, and was satisfied that some matter was forming in his leg, and, by the advice of the defendant, a Dr Hilbers was called in to prescribe. In a few days a swelling in the leg broke, and the plaintiff in the month of June complained of a shivering in his back, and said he believed more matter was forming. The defendant then said the plaintiff's spine was affected, and he applied his lotions and plasters to his back and body. The plaintiff soon afterwards complained of pain in his head, and the defendant assured him that he had a softening of the brain, and applied his white lotion to his head. Upon this point the plaintiff admitted the defendant was right, for, he said, if his brain had not been "very soft" he should not have continued under the defendant's treatment so long. However, the plaintiff left Brighton on the 11th of October, 1858, and was confined to his bed for seventeen weeks; but he had since recovered his general health, though his knee, owing to the defendant's unskilfulness, was permanently contracted, and he could not walk without a crutch. The defendant used to speak in strong terms of condemnation of the practice of medical men, and said that they wanted a "hanging day" amongst them, because they applied leeches. It appeared on the cross-examination of the plaintiff that the defendant had attended him a hundred and seventeen times, his attendances extending from half an hour to two hours each time. The defendant had also brought an action against the plaintiff to recover payment; upon which the plaintiff brought the present action to recover damages for the defendant's negligent and unskilful treatment.

Several surgical witnesses were called, and gave evidence that the defendant's treatment of the plantiff's leg was unskilful and improper. These were Mr Farwell and Mr Wood, and a third surgeon, named Taylor, who attended the plaintiff when he left Brighton; and their evidence was supported by a surgeon of the city of Oxford.

On the part of the defendant, evidence was given that he was ill, and unable to attend the trial; but his assistant, a young man named Bennett, was called, and also a Dr Hilbers, and, according to their opinions, the defendant's treatment was very skilful and generally successful. There appeared to be no doubt that the defendant enjoyed a considerable reputation, and had a great number of patients, and it was urged on his behalf that this action was brought only with the view to evade payment of the defendant's demand for his long and attentive services.

The jury ultimately found for defendant—Damages 300*l.*

YORK, July 14th.

(Before Mr Baron Willes.)

ALLEGED MANSLAUGHTER BY A QUACK DOCTOR.

George Swinson, a quack doctor, was charged with the manslaughter of John Batty, on the 22nd of March last, at Sheffield. The features of the case were of an extraordinary character, differing materially from ordinary cases of manslaughter, the prisoner having, it was alleged, caused the death of John Batty, by gross and culpable negligence in the treatment of a disease under which that person was labouring. Batty, it appeared, was a sheep-shear maker at Grimesthorpe, and the prisoner was a toll-bar keeper at Pitsmoor, both of which places are in the neighbourhood of Sheffield. The prisoner had obtained considerable popularity in his practice as a quack doctor; and Batty, having a wound upon his leg, was induced by Swinson's reputation to visit him. The prisoner, on looking at the wound, which was in the neighbourhood of some large bloodvessels, made an application to it which caused considerable pain. On four other occasions the prisoner treated the wound, which on each visit was enlarged in size. The last occasion was the 22nd of March. After leaving the prisoner, the deceased proceeded on his way home; but when he had got about half-way, the pain which he was suffering became so intense that he cried out for assistance. A person coming up to him found blood flowing from the leg of deceased's trousers, and endeavoured to remove him to a stable close by. The deceased fainted on his way, and died from loss of blood after he had been laid down about twenty minutes. A post-mortem examination of the body of the deceased was made, when it was found that caustic had been applied to the wound, and had eaten through the vein in its vicinity. The deceased's death had resulted from loss of blood. The prisoner, on hearing of the death of his patient, remarked that it was a bad job, and that it would be a 'York job' for him. For the prosecution, it was urged that the death of the deceased had been caused by the ignorance and rashness of the prisoner. Mr D. Seymour, however, urged in defence that the evidence showed that the vein which had been ruptured was in a varicose condition, and had burst from oxer-exertion. The jury acquitted the prisoner.

Births, Marriages, and Deaths.

BIRTHS.

Brown.—July 12, at Hampstead, the wife of R. G. Brown, Ex.-L.R.C.P., of twins, son and daughter.

Beck.—July 14, at Belfast, the wife of John Woods Beck, M.D., of a son.

Cannon.—July 17, at Rockville, Cheltenham, the wife of Dr Henry Mills Cannon, Surgeon H.M.'s Bengal Army, of a daughter.

Davis.—July 18, at Addison road North, the wife of Henry R. Davis, Esq., L.R.C.P.E., of a daughter.

Sturt.—July 17, at Margaret street, Cavendish square, the wife of T. J. Sturt, M.D., of a son.

MARRIAGES.

Fish—Chesterman.—July 17, at the Parish Church, Banbury, the Rev. John D. Fish, M.A., to Henrietta Barnes, youngest daughter of Shearman Chesterman, Esq., M.R.C.S., of that town.

M'Andrew—Cockrell.—July 13, at St Mary's, Twickenham, Wm. Henry M'Andrew, M.D., of H.M.'s 57th Regiment, Bombay, to Julia Margaret Cockrell, Woodlands, Twickenham park.

Merryweather—Hill.—July 12, at Ledbury, Henry Merryweather, Esq., M.R.C.S., of Sheffield, to Mary Emmeline, second daughter of the late Thomas Hill, Esq., of the Old Rock, Dymock, Gloucestershire.

DEATHS.

Anderson.—July 8, at Tyree, James Anderson, L.R.C.S. Edin.

Bowen.—July 13, at Park villas, Ilford, Essex, aged 26, Jane, the wife of Dr Bowen, late Surgeon to the Royal Hibernian Military School, Dublin.

Chick.—July 13, at his residence, Great Jackson street, Hulme, Manchester, Edwin Reynolds Chick, Esq., L.R.C.P. Edin., M.R.C.S. Eng., L.F.P.S. Glas.

Crawford.—May 23, at Secunderabad, Clara Frances, wife of Thomas Crawford, M.D., 18th (Royal Irish) Regiment, and daughter of the late Richard Morrison, Esq., of Dublin.

Drew.—July 5, at Milford, Pembrokeshire, John Drew, Surgeon R.N., Admiralty Surgeon and Agent, and Surgeon to the Hon. Trinity Corporation at Milford, aged 69.

Fyfe.—July 9, at 37 Pleasant street, Clarence street, Liverpool, James Corson Fyfe, L.R.C.S. Edin.

Graves.—July 13, at Barton street, Gloucester, Standish Ryves, eldest son of R. W. Graves, Esq., F.R.C.S., aged 11 years.

Gorman.—May 30, at Trincomalee, of phthisis, James Gorman, L.R.C.S. Edin., Staff Assistant-Surgeon, Army, aged 29.

Hickman.—July 12, at Duke street, St James's, William Hickman, Esq., M.R.C.S., aged 28, second son of — Hickman, Esq.

Lind.—July 10, at Corstorphine Lodge, Ryde, Isle of Wight, James Player Lind, M.D., late of Wadham College, Oxon, Justice of the Peace for the County of Hants, and for many years Chairman of the Bench of Magistrates at Ryde, in his 70th year.

Morgan.—May 21, at Old Calabar, West Coast of Africa, John Steane Morgan, Esq., late of Whitby, Yorkshire, second son of the late Wm. Hoskyns Morgan, Esq., Surgeon R.N., of Hereford, aged 37.

Parkin.—July 11, at Hightown, Yorkshire, John Parkin, M.R.C.S., aged 37.

Reid.—May 26, at Allahabad, East Indies, of typhus fever, Harry Reid, L.F.P.S. Glasgow, M.D. University of St Andrew's, Assistant-Surgeon of H.M's 75th Regiment.

Williamson.—July 4, at his residence, Aberdeen, Joseph Williamson, M.D. University of Edinburgh, M.R.C.S. Eng., aged 50.

MEDICAL NEWS.

Apothecaries' Hall. — Name of gentleman who passed the Examination in the Science and Practice of Medicine, and received his Certificate to Practise, on Thursday, July 12: —Henry Chrippes Sherwin, Pulborough. The following gentlemen also on the same day passed their First Examination:—Charles Brook, Lincoln; Nathaniel Englcheart Cresswell, St Mary's Hospital; Humphry Davy, St. Mary's Hospital; Richard Dawson, University College; Thomas Griffiths, University College; Horace Sydney Howell, St Bartholomew's Hospital; John Talfourd Jones, University College; George Albert Miskin, St Thomas's Hospital; Thomas Neatby, Barnsley; Frederick Thomas Roberts, University College; Nathaniel Gilbert Scott, St Bartholomew's Hospital; Richard Lewis Shone, University College; Thomas Galston Wollaston, King's College.

Royal College of Surgeons.—At a Meeting of the Council of the College, on the 12th inst., Mr John Flint South was elected President; Mr Cæsar Henry Hawkins, F.R.S., and Mr James Luke, F.R.S., were elected Vice-Presidents, of the College. This is the second time these honours have been respectively conferred on these distinguished Surgeons.

British Medical Association.—We learn that at the meeting of the Metropolitan Counties Branch, held on Tuesday last, it was unanimously resolved to invite the Association to meet in London in 1862.

Legacies.—The late Mr J. Mayer, of Hanley, has left several liberal legacies to public institutions; amongst them, 1,000*l.* to the Royal Free Hospital, 500*l.* to the Brompton Hospital for Consumption, and 1,000*l.* to the North Staffordshire Infirmary.

The Surgeon's Daughter.—The 'Indépendance Belge' announces the intended marriage of the daughter of Professor Velpeau with a member of the French Legislative Assembly and chamberlain of the Emperor. The portion of the young lady is to be 25,000*l.* and an outfit worth 2,000*l.*

Braidism in France.—The French are very fond of connecting proper names with the designation of new theories in science or art. Faradization is now, amongst our neighbours, as common an expression as Galvanism; and now we find the following book announced: 'Theoretical and Practical Course of Lectures on Braidism, or Nervous Hypnotism, considered in its relations with Psychology, Physiology, and Pathology.'

Militia Surgeons.—Mr Sidney Herbert has received a deputation to present a requisition, signed by 47 colonels and 109 members of Parliament, directing his attention to the present unsatisfactory state of the Militia Surgeons, and urging on him the justice and propriety of placing these gentlemen in a more remunerative and satisfactory position.

Marriages of First Cousins. — Dr Bernis, of Kentucky, has found that ten per cent. of the deaf and dumb, five per cent. of the blind, and fifteen per cent. of the idiots, admitted into the various charitable institutions of the United States, are the issues of marriages of first cousins. These unions are now prohibited in certain States, and especially in Kentucky.

Somnambulists Fined.—In Paris, professional somnambulists have frequently been condemned to fine and imprisonment for obtaining money on pretext of indicating occult facts. Two persons named Nicolas, man and wife, were this week committed to prison for one month, and each fined 50 fr., for swindling out of 20 fr. a man who had been robbed, and to whom they pretended falsely to indicate the thieves.

Poor-law Medical Reform Association: Students' Branch.—A meeting of the committee was held on Thursday evening, the 12th

instant, at the Freemasons' Tavern. In the absence of Mr E. Hart, Mr Felch, of the Middlesex Hospital, was voted to the chair. Mr Sutton read a letter from Dr Tilbury Fox, stating that his numerous engagements compelled him, with great regret, to resign the office of secretary. A similar communication was received from Mr Felch, resigning the treasurership. A vote of thanks was proposed to the retiring officers, for their assiduity in carrying on the work. Mr Galton (Guy's) and Mr Sutton (Middlesex) were then requested to undertake, solely, the duties of treasurer and secretary, which had hitherto been fulfilled by two gentlemen. It was announced that Mr Pigott, M.P., was about to bring in a new Bill for Poor-law Medical Reform, though, from the lateness of the session, it was feared it would not pass into law this year. Mr W. Brett (Westminster) strongly urged the committee not to allow the attention of the profession and the public to be turned from this important measure. He suggested that a circular should be sent to all the provincial schools of medicine, calling upon the students to hold meetings and to petition Parliament. Handbills should also be printed, and affixed to the notice-boards of the London hospitals, inviting the students to sign the petition which was drawn up at the late aggregate meeting in St Martin's Hall. Mr Brett thought it would be well to call meetings of the working classes, and lay the question before them. It concerned the poor more than the medical man. His suggestions were adopted.

Coroner's Court.—The annals of our criminal courts have recently furnished us with a case of some medico-legal interest. Geo. Solloway, an inmate of Windsor Workhouse, was charged at the Abingdon assizes on the 10th ult. with the manslaughter of Wm. Wickens, a pauper, on March 6th last. From the evidence it appeared that deceased was an idiot, and was suffering from hemiplegia. He required a bath, and the prisoner, as a part of his duty, placed deceased in a warm bath, in which he remained half an hour. During this time he was seen to shiver. He was taken out and put to bed, when almost immediately afterwards he died. The medical witness attributed "his death to apoplexy. Had made no post-mortem examination, as the coroner had given him no order to do so. Deceased might have died of apoplexy of the lungs or disease of the heart." Mr Justice Hill observed, "that as death might have arisen from natural causes, it would be wrong to convict the prisoner; but if proper care had been used, the necessary evidence might have been got." The jury acquitted the prisoner. If it were a mere question of economy that no post-mortem was made, the authorities cannot but bear the blame of a short-sighted policy; for had an autopsy exhibited to the surgeon facts sufficient to account for the man's death by natural causes, then there would have been an end of this case, the costs of the prosecution saved, and the accused relieved from the horrible imputation which has attached to his name during the last four months. If, on the other hand, evidence had been afforded indicative of death by any act or by the wilful neglect of the accused, then the case could have satisfactorily gone into court, and the prisoner's alleged guilt established. Now, however, the case resolves itself into one of two propositions—either that an innocent man has been committed to await his trial on a charge of manslaughter, when such committal might have been averted by proper medical evidence, or a guilty person has escaped punishment through the absence of a most important branch of evidence. This case, however painful in some respects, is gratifying to the Profession, as exhibiting the rapidly-increasing importance of the medico-legal branch of science; and it is our earnest wish that the observations made by the learned judge may have due weight upon prosecuting authorities in future, and induce them to set more value on medico-legal evidence.

APPOINTMENTS FOR THE WEEK.

Wednesday, July 25.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, July 26.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2½ p.m.

London Home.—2 p.m.

Friday, July 27.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, July 28.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, July 30.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, July 31.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

Medicus.—It is difficult to know what to recommend, as you seem to have exhausted the Pharmacopœia. Sciatica is sometimes a very obstinate affection: we have known hot-air baths do great good; injection of a solution of morphia under the skin, between the tuberosity of the ischium and the hip, has been found beneficial in some cases, but it has failed in others. We have noticed sciatica to have often had an intermittent character; in such cases quinine and arsenic are beneficial, with change of air. We should not despair of these latter resources, although in your case they may appear formerly to have failed. Try the effect of a mild galvanic current.

J. W. H.—It is unlikely that the proposition will be carried out.

A Subscriber.—We have no confidence in it; we have tried it frequently, but it has failed to produce a beneficial effect.

Omega's letter on "Special Hospitals" received.

Dr Chas. W. is thanked.

The Munster News.—Received. The case reported is a very singular one, but the evidence is not clear enough to endow it with medical interest.

Mr Johnson.—1st. No.—2nd. Yes.

Edinensis.—We are obliged. It shall be attended to.

M.R.C.S. Eng. and L.A.C.—We are not aware of any separate treatise on the subject.

A Poor-law Medical Officer.—Received. We are unable to answer your question satisfactorily.

A Student.—You will come under the old regulations.

Mr Davis.—Yes.

A Subscriber (Ramsgate).—You had better write to Weiss, in the Strand, who will inform you.

Mr S. B.—The qualifications are sufficient.

Dr Gibson's Cases of Diptheria shall appear next week.

H. H. G.—No. The appointment of District Vaccinator is independent of that of Medical Officer. The publisher will attend to the requests contained in your note.

M. A. B.—Such an appointment as you describe would be most desirable for you, and might be obtained by application to the great shipowners. A recommendation would be an advantage.

Mr Benson.—1st. Yes. 2nd. Yes.

Chirurgus (Boston).—It was so formerly; but the rule has been rescinded.

Dr W. H. T.—Apply to the Registrar.

A General Practitioner.—The Medical Council have nearly completed their arrangements for a new Pharmacopœia for the three kingdoms. It will probably be ready by the beginning of next year. The inconvenience resulting from the present discrepancies must be, as you say, very great in some districts.

Medical Crotchets.

"A learned doctor of wry law,
And would make three to cure one flaw."
Hudibras.

To the Editor of the Medical Circular.

Sir,—We are at present in a whirl of new, but false, excitements on paper: might we not all as well go easy? We are to have midwifery "made easy," false presentations corrected by fanciful external manipulation. We are to have syphilitic eruptions cured by arsenic, or "short and energetic courses of mercury," which would get well without either. But "syphilisation," it seems—as you suspected a little while ago—is not only not orthodox, but it is a blunder, as bad as the arsenic and mercury. Patients are occasionally seen admitted in such hospitals as Guy's or St Bartholomew's, who have been turned out "cured" from the Lock Hospital by the so-called brilliant "syphilisation" method, *quoad* their simple primary sores on the genitals; but their legs or limbs, poor wretches! present a miserable mass of nasty ulcers, which are the result of the brilliant inoculating process: nay, what is more, in ninety-nine cases out of a hundred, these nasty experiments, or ulcers, are admitted to be new flaws to cure an old one, and have done neither good nor harm; in other words, they are flaws or blunders from beginning to end. It answers the book-publishers, but nobody ought to be misled by their dreams. One need not say what mischief—greatly to the discredit of legitimate medicine—the "energetic" courses of mercury do, too, in this disease. We have an hospital for urinary diseases and "stone," probably much needed, but, it is said, violently opposed by Dr Hassall; and, peradventure, an hospital for crooked elbows and knees is said to be in process of orthopœdic incubation—to be opposed by some Great Northern somebody else yet there is room for all, as our largest hospitals are becoming careless and inadequate to the great work devolving on them and such jobs, that men like MacWhinnie are obliged to cut them!

The "Educational Council," at the eleventh hour, have published a much-required code of regulations on the education of young medical men in future, very much needed;—one of the good, much-desired results of the Oxford "revivals" and parliamentary interference: and as to Apothecaries—as wisely suspected not long ago in the Medical Circular, the Apothecaries' Hall Corporation refuses to permit the College of Physicians to establish another grade of General Practitioner or Apothecary. So far so good.

Some one asks, what is the Medical Circular doing? We owe the chief of these reforms to it, and your correction of medical "fancies" are invaluable. Yours, M.D.

M.R.C.S. (Birmingham).—We believe the practice is founded on an error. There is nothing gained by placing a patient two or three times under chloroform the week previous to the day of operation. We know it is very common, but it is now decided to be a custom more "honoured in the breach than the observance."

Foreign Graduates and the Medical Council.

To the Editor of the Medical Circular.

Sir,—Permit me to say that I think "Paul Pry" falls into an error in the conclusion he draws from his statistics, as published in his letter in your last impression. He seems to imagine that all the foreign graduates whose names do not appear on the 'Medical Register' hold diplomas that the Council have refused to recognise. I take it that this is by no means correct. Many foreign graduates, in common with a great number of British ones, look upon the new Act as a sham and a delusion, and have not, therefore, thought fit to apply to have their names enrolled in a useless register, at an expense of a couple of guineas. For my own part, I hold a foreign diploma, obtained after a regular course of study and a rigid examination, and do not, therefore, see how the Council could refuse to register it, were I to make application. I have not, however, done so, and until some much greater advantages are to be obtained for my two guineas, do not intend—more especially as the Medical Directory publishes a far more complete list of practitioners, and levies no tax upon them for inserting their names. The truth is, that the 'Register' does not at present contain the names of half the qualified medical men in the country, and never will until they are inserted free of charge. Registration literally confers no advantages, and large numbers, therefore, object to pay for it.

July 14th, 1860. A Foreign Graduate.

Mr Milton will have seen that the continuation of his excellent lectures was inserted last week.

Mr Whitton's communication has been received, but declined, having been published in another journal.

Letters received from T. Webb, H. Tucker, S. Davidson, R. Jones, J. Tufnell, Dr C. Phillips, H. Berkeley, H. H. Taylor, J. Popjoy, T. M. Clewley, J. Tucker, J. T. Hussey, Dr Wilkinson, G. G. Smith, Dr Lowne, W. H. Oliver, Dr Ffolliott.

Briet's Celebrated Patent

GAZOGENE or AERATED WATERS APPARATUS, for the immediate production of SODA WATER, GINGER BEER, SPARKLING WINE, LEMONADE, &c.

SOLE AGENTS FOR GREAT BRITAIN,

MATHIEU AND FRIQUET,

5A Little James Street, Bedford Row, London, W.C.

This agency was first established by one of the Partners (Mr F. Mathieu), who kept it from 1851 to 1854, and is now a Branch of the Patentees' Paris Establishment. It is the only house in the United Kingdom supplied by the Patentees, and there is no other having the right to use the name of Agents for for them.

MATHIEU and FRIQUET are manufacturing the GENUINE LEMON SYRUP made from the actual FRUIT. When used with the Aërated Water from the Gazogene, it produces a pure and wholesome Sparkling Lemonade of the most exquisite and refined flavour.

Powders for Generating Gas in the Apparatus. Special and able Workmen from the Paris Manufactory are kept on the premises for the prompt and sound repairing of the Gazogenes, at low charges. No other repairers appointed by the Manufacturers.

WHOLESALE AND FOR EXPORTATION ONLY.

Price Lists sent on application on receipt of Busine Card.

Label Warehouse, Letter-Press, Copper-Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctors' Commons, London, E.C.

H. Silverlock's stock of LABELS for DISPENSING purposes, having been recently revised and enlarged, now consists of upwards of 800 different kinds. Yellow and Green Labels for Drug Bottles, Drawers, &c., at per book or dozen; a Book, containing a selection in general use in Surgeries or Dispensaries, 10s. 6d.

Printed Catalogues of the above may be had, post free on application.

Printing of every description at moderate prices.

A New Discovery.—Mr

HOWARD, Surgeon-Dentist, 52 Fleet street, has introduced an entirely NEW DESCRIPTION of ARTIFICIAL TEETH, fixed without springs, wires, or ligatures. They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will never CHANGE COLOUR OR DECAY, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed teeth rendered sound and useful in mastication. 52 Fleet street.

At home from ten till five.

REDUCTION OF THE WINE DUTIES.

The European and Colonial

WINE COMPANY,

122 PALLMALL, S.W., LONDON.

The Promoters of the above Company beg to announce that they have reduced their Tariff of Prices, and now offer their Patrons the full benefit of the new enactment.

RUPTURES. BY ROYAL LETTERS PATENT.

White's Moc-main Lever

TRUSS is allowed by upwards of 200 Medical Gentlemen to be the most effective invention in the curative treatment of HERNIA. The use of a steel spring, so often hurtful in its effects, is here avoided: a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER, fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had, and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer,

JOHN WHITE, 228 Piccadilly, London.

Price of a Single Truss, 16s., 21s., 26s. 6d. and 31s. 6d.—Postage, 1s.

Price of a Double Truss, 31s. 6d., 42s. and 52s. 6d.—Postage, 1s. 8d.

Price of an Umbilical Truss, 42s., and 52s. 6d.

Postage, 1s. 10d.

Elastic Stockings for Vari-

COSE VEINS, and all cases of Weakness and Swelling of the Legs, Sprains, &c. They are porous, light in texture, and inexpensive, and are drawn on like an ordinary Stocking. Price 3s. 6d., 7s. 6d., 10s., and 16s. each. Postage, 6d.

JOHN WHITE, MANUFACTURER,

228 Piccadilly, London.

Notice—Behenna and Co.

ACCOUNTANTS, conduct all business entrusted to them, with secrecy, economy, and despatch. Accounts prepared in Bankruptcy and Insolvency. Arrangements made with Creditors. G. VAN ABBOTT, 13 Basinghall street, E.C.

Medical Practitioners Sup-

plied with ASSISTANTS, gratis, by MAIR and SONS, 34 Bedford street, Strand, who also DISPOSE of PRACTICES on moderate terms.

Health, Fresh Air, and Pure

WATER.—By her Majesty's Letters Patent.—CONDY'S FLUID contains nascent OXYGEN, Nature's true and only purifying agent; instantly removes all offensive smells; renders impure water fresh, and the air pure; when diluted for use, is of a beautiful rose-colour, not soiling the finest linen; is harmless and particularly adapted for toilet use, being both refreshing and exhilarating. The Medical Profession have expressed their unqualified approbation of its merits.—One gallon makes 200 gallons adapted for use. The cooling, healing, gently stimulating, and invigorating properties of this fluid, render it, when diluted, a lotion possessing peculiar and valuable characteristics, whether for bathing the body of invalids, incorporating in poultices, washing and healing wounds, or for general purposes of ablution when in health. Patronized by the Board of Health and most public departments, Hospitals, Schools, and adopted by the India Council in preference to all other disinfectants. In bottles, 6d., 1s., and 2s.; stronger and purer, 1s., 2s., and 4s.

CONDY'S PATENT HEALTH POWDER also contains nascent OXYGEN, is odourless and destroys all smells. Sold in bottles, 1s. 6d. and 3s.; and in casks, 1 cwt.; 36s. Wholesale Agents, John Bell and Co., Chemists, 338 Oxford street; Savory and Moore, New Bond street, Butler and Crispe, 4 Cheapside; W. Twinberrow, 2 Edwards street, Portman square; and Twinberrow and Co., Chemists, Worcester.—Chemical Works, Battersea, S.W.

Bennett's Watches, 65 & 64

CHEAPSIDE, in gold and silver, in great variety, of every construction and price, from 3 to 60 Guineas. Every Watch skilfully examined, and its correct performance is guaranteed. Free and safe by post.

Money Orders to JOHN BENNETT, Watch Manufactory, 65 and 64 Cheapside.

CLINICAL LECTURES.

ON THE DIFFICULTIES THAT ATTEND THE DIAGNOSIS OF THE NERVOUS AFFECTIONS

KNOWN AS INTERMITTENT TETANUS, TETANILLE, IDIOPATHIC MUSCULAR SPASMS, ETC.

DELIVERED AT THE HÔTEL-DIEU,
By M. TROUSSEAU.

There is at present in the Salle St Bernard a woman, twenty-five years of age, whose morbid state is one of great practical interest, on account chiefly of the many possible errors that beset the diagnosis. For several months she has had a severe diarrhœa, but unaccompanied with either fever or nocturnal perspirations, or any lesion on the part of the respiratory organs. To the great privations she has had to endure have sometimes been added the painful torments of hunger. Her husband, attacked with typhus fever, was admitted two months ago into this hospital, and his lengthened convalescence has only contributed to prolong the privations of the *ménage*.

This woman has seven or eight stools during the day, and as many in the night. I ordered for her preparations of bark and sub-nitrate of bismuth, and then a good alimentary regimen. Things were in this state when, yesterday, she complained of numbness of both arms, so that she could neither dress herself, nor hold a spoon so as to eat her *potage*. In the evening she had, as well as this morning again, several attacks of *contraction;* and it is to this singular affection I now wish to direct your attention, for it is one that does not fail to frighten many persons when they do not know that they have to do with an affair destitute of all danger.

If this affection existed in the times of our fathers, which I do not deny, it was at least all but unknown, and for a description of it we are indebted to our own times. The archives of science possess here and there cases, such as those collected by Dance (On Intermittent Tetanus), by Laberge and Murdoch, and by Imbert Gourbeyre, professor to the Preparatory School of Medicine of Clermont, who, in 1844, endeavoured, in his inaugural thesis, to collect the scattered fragments that had been then written on the singular disease I am going to describe to you: but from all these vague cases there was not deduced any complete body of doctrine at the time that M. Delpech, one of my *internes*, published his memoir (1845) on Idiopathic Muscular Spasms, in which were contained many cases that had been carefully observed. Then, in 1852, we had, lastly, the thesis of Lucien Corvisart on *Tétanille* (Little Tetanus).

In my practice at the Neckar Hospital, during the years 1840, 1841, and 1842, I at least met with cases in wet-nurses, and then thought I had a right to give to this affection the name of the *wet-nurse's rheumatic contraction*. But since that time I have seen the disease in men, children, and women who were not in the puerperal state. To enable you to seize more exactly the diagnostic characteristics of this affection, I will admit that it assumes three forms—a division, however, that is purely arbitrary. 1st, a benign form; 2nd, a middle form; and 3rd, a severe form.

1st. *The Benign Form.*—In this variety, which mostly attacks women, the patient experiences formication in the hands and feet, stiffness of the fingers and toes; the fingers next become rigid and firmly drawn together. The thumb is in a state of strong adduction, and the fingers are more or less bent on the thumb, so that the hand resembles a cone, or the hand of a person holding a pen, or, better still, the hand of the accoucheur. The palm of the hand becomes concave from the action of the adductors and their opponents, and the transverse diameter of the metacarpal portion is lessened. The singular way in which the fingers are placed is often sufficient to point out the disease. The spasms under consideration are accompanied with hardness of the muscles of the arm and forearm, which soon disappears and soon returns. The formication and contractions extend now to one of the superior extremities, now to one of the inferior, or to the superior extremities only, or to the inferior; but at other times, and simultaneously, to the two sides and to all the members. But all this is so little painful and attended with so little severity, that the patients themselves pay but little attention to it; the more so that in this benign form there are no general symptoms.

2nd. *Middle Form.*—Besides the local disturbances which I have just enumerated, there is in this form a slight degree of fever, the duration of which is about seven or eight days, and which generally does not persist unless the spasms are renewed. The appetite is lessened, and there is a certain degree of discomfort; but these general symptoms show nothing of a serious nature. As to the contractions, they occasion more suffering and return more frequently; they attack the muscles of the face, the motor muscles of the eye, and the muscles of the pharynx. In some instances the muscles of the tongue are affected, and then the patient can no longer speak; but this is not usual while the hands and feet are the seat of the spasms. The fingers are always drawn together.

3rd. *The Severe Form.*—Four years ago my colleague and friend, Dr Lasègue, was at the Prefecture of Police, where his duties required his attendance, when there was brought to him a young man, a shoemaker, eighteen years of age, who was attacked, it was said, with epilepsy, and who had beeen found in a state of complete drunkenness lying on a heap of stones near the Hôtel de Ville. He was rigid like a bar of iron, the jaws firmly clenched together, and the hand transformed to the accoucheur's hand. After talking with him, and becoming convinced that the disease was not epilepsy, M. Lasègue sent the young man to the Hôtel-Dieu, when he came under my care. The following are the curious phenomena which we then remarked:—The patient, as if suddenly struck, fell to the ground in a state of tetanic rigidity; the muscles of the neck, chest, and abdomen became convulsively rigid, and bent the trunk forward. The respiration after some moments became extremely difficult, and there was a true attack of orthopnœa, which, happily, was but of short duration, and could only be accounted for by suspension of the functions of the laryngeal muscles. The face was red and animated, the lips violet, and the jugular veins swollen.

I have been witness a great many times to attacks of this kind, all of terrible vehemence, and accompanied with pulmonary choking, resembling in these respects attacks of tetanus. No sooner had the spasms ceased, than this person began to talk with a certain degree of gaiety, though he expressed himself with difficulty; got up, assisted his comrades, swept, made their beds, &c.; in short, lived the ordinary life of those who attend to the patients. In the intervals between his crises he had quite recovered his health, and ate with appetite. This patient usually experiences, just as the paroxysm begins, formication in the arms; he can still move the hand, but this soon becomes concave like the hollowed hand of the beggar, then bends, and the arm becomes rigid, while acute pain, that has been compared to cramp, now takes place. The numbness, formication, and cramp are then the first phenomena that characterise an attack, which does not reach the *summum* of its intensity for ten or fifteen minutes; and then the spasms have invaded the superior and inferior extremities, as well as the face, the jaws, and the tongue. The rigidity is thus marked by its migration, by its short duration, and a slight degree of fever (*middle form*); or it is accompanied by violent pyrexia (*the severe form*).

Even should a patient have no symptom for twenty-four, forty-eight, seventy-two, or a hundred hours, it is yet always possible to cause their renewal. In fact, chance showed me how these spasms may be brought on at pleasure. One day at the Neckar Hospital, (in 1839,) I was occupied with the case of a wet-nurse, the subject of violent spasmodic attacks, and I then entertained, as I do now, the notion that this affection is one of a rheumatic kind. I asked for a bandage, placed it on the arm, and desired one of the pupils to practise venesection in my presence, cutting the vein longitudinally, and not transversely; for it is in this manner I think the operation should be done. All at once there was another attack. The ligature was removed and placed on the other arm, and the same thing followed, accompanied with an identical state of the lower extremities. Every time I have since wished to repeat this experiment, I have constantly remarked the same occurrence; and this morning you yourselves have seen, in the woman in the Salle St Barnard, with what rapidity an attack can be induced. I thought, at first, that an explanation of this fact could be found in supposing that this artificial contraction might be owing to momentary venous congestion; but when I compressed the artery so much that no more blood was felt in the arm, a similar effect was still produced. You are ready to say in reply, that the cause lies in the momentary interruption of the arterial circulation—a supposition as groundless as the former, for the whole must be referred altogether to the nervous system.

(To be continued.)

DIPHTHERIA.

ANALYSIS OF SIX CASES OCCURRING IN MY PRACTICE IN THE WINTER OF 1858-59. ATTENDED BY THOMAS GIBSON, M.D., Orton.

1. M. A., female, aged six years; duration of disease, three weeks; recovery.

2. W. B., male, thirty-seven years of age; ill nine days; recovery.

3. S. A., aged eleven years; observed six hours; died.

4. A. S., male, aged eighteen months; ill one month; the exudation on the fauces, &c., recurring during the last week of the illness, and resulting in death, with symptoms of cramp.

5. Aged thirteen years, female; observed twenty-four hours; death resulted as in the former case, with similar symptoms.

6. Aged seven years, male; observed for three weeks; recovery.

All the above cases put on the same symptoms, corresponding exactly in the nature of the exudation and the affection of the respiratory apparatus, with a decided tendency to coma in the fatal cases.

No. 1. The patient expectorated large quantities of tubulated false membrane, and with great relief, the paroxysms uniformly abating in intensity, and the cerebral symptoms mitigating. The treatment pursued was a mixture of the stimulating with the antiphlogistic, with a liberal supply of port-wine, with beef-tea, alternating when the exudation was more than usual in quantity, and when the breathing was oppressed, with an emetic of the tartarised antimony, inhala-

tion of steam, purgative doses of calomel, &c., pencilling twice daily the fauces with tr. ferri mnr. ℥ij., aq. puræ ad ℥ss., and the administration of a mixture composed of nitro-muriatic acid in bitter infusion. In Nos. 2, 4, and 6, the same treatment was adopted with beneficial effects, except in No. 4, which, owing to the relapse and the great difficulty of effectually sponging the throat of young children, unfortunately terminated fatally.

As a rule in this country, I find, on inquiries rigidly made, that when the patients have been seen by the medical attendant early, and treated on this principle, they have uniformly done well; but very often the patients themselves have not observed any serious illness until the disease had so far advanced as to be beyond the reach of medical aid: for when the fauces have been in an œdematous condition for a length of time, the system gives way, and every attempt is rendered futile by the croupy respiration and the speedy death of the patient, which not unfrequently is preceded by convulsions, owing to the non-arterialisation of the blood in the lungs. In cases Nos. 3 and 5 the unfortunate patients were in that condition. I hold that diphtheria requires support at the very commencement; and in this the treatment differs from scarlatina, which will not bear this kind of treatment until the fever is subdued.

THE SPIRIT OF THE PERIODICALS.

Dr S. H. Hobart, of Cork, reports in the 'Dublin Quarterly Journal' the following *Case of Double Monster:*

"On September 23rd, 1860, I was called on to see Mary Barber, then in labour of her first child. On examination I found two feet protruding from the vulva, one being rather lower down than the other. This was about 1 o'clock p.m. The membranes, as far as I could ascertain, had ruptured about 8 o'clock a.m., and the feet had been protruding about two hours previous to my visit. Very little uterine action was going on. I attempted to draw down the foot which had least descended, but found it unyielding, and observed that it was turned nearly at right angles to the other; and the idea suggested itself that they might be the feet of different children; but the fact of their being right and left rendered this less probable. A second attempt to draw down the upper foot having failed, I passed the index and middle finger into the vagina, and could just reach what proved to be a third foot, and, on then following the line of the lowest leg, the breech of this child could be felt, its second leg being flexed on the abdomen. Not being able to bring down this child by moderate traction on the leg which was protruded, I returned home for a blunt hook, and, at the same time, availed myself of the assistance of my friend Dr Bernard.

"On applying the hook over the groin of the first child, or that which had advanced most, we divided the force, Dr Bernard drawing on the protruding leg, while I assisted with the hook, at the same time endeavouring to push up the feet of the second child. In this way considerable advance was made, without exercising undue pressure on one part; and by the time the breech of the first child had descended into the hollow of the sacrum, the feet of the second had gone up completely above the brim of the pelvis. Further advance now became more difficult, the force required steadily increasing as the child advanced more and more. At length the breech was brought down beyond the external parts, and the second leg liberated from the vagina; beyond this, however, no force which appeared warranted could move the child.

"On now examining the posterior part of the vagina, and higher up, the feet of the second child could be felt descending into the pelvis; they appeared to embrace the body of the first child, and, on applying extension to the latter, they descended with it, as if entangled in it, and, on relaxing the extension, all retreated together. On passing my hand along the abdomen of the first child, which was turned towards the mother's pubes, I could not discover any cord, though the hand passed higher up than the proper umbilical region; but it appeared as if a fold of integument occupied its place, and this seemed to be forcibly drawn up into the mother's abdomen. At this stage (my father not being in town) I called on Dr Harvey, and described the state of the case as I have now done, adding that I was strongly inclined to think that there was union between the abdomens of the two children, that the fold of integument I have referred to was the isthmus of connection between them, and that perhaps a cord more directly attached to the other fœtus supplied the wants of both. With his usual kindness, he immediately volunteered to accompany me to the poor woman's house, when, after a good deal of investigation, he succeeded in hooking his finger round a cord. On endeavouring, however, to draw it down sufficiently to ascertain to which child it belonged, it gave way under the finger as if rotten; but on catching the short end between the finger and thumb, its attachment could be traced to the first child.

"Dr Harvey now suggested that what I have described as a fold of integument as the upper part of the child's abdomen might be deceptive, and the state of parts present be owing to the lateral compression causing a sort of puckering of the integuments in front; and the fact that the finger could be sunk into a deep sulcus at the side of this fold, and that the lower margin of the ribs could be traced from either side to the mesial line, rendered it difficult to conceive that the abdomen could be extensively united; besides, the height at which the parts were placed made it impossible to arrive at a positive diagnosis. These points, together with the extreme improbability of the thing, caused us almost to lose sight of the idea of abdominal union, especially as the remarkable manner in which the legs of the second child embraced the body of the first appeared in some measure to account for the difficulty of bringing the latter down. More unsparing efforts were now made to accomplish this object, it being no longer necessary to avoid injuring the child, as it was of course dead, the cord having been accidentally ruptured some time before, as I have mentioned; but the utmost extension that Dr Bernard and I could exercise together scarcely brought it down an inch farther. Dr Harvey now succeeded in passing the blunt hook over one shoulder, and in bringing down the arm; but this, though it allowed one leg of the second child to pass up, did not appear to improve matters in the slightest degree. Nearly two hours having been thus spent in these almost fruitless efforts, the woman became very impatient and much exhausted, and it was thought advisable to postpone further interference for the present; and Dr Harvey recommended that I should, in the meantime, get my father, Dr Hobart, to see the case, and consult with him as to the advisability of giving ergot, and so establishing uterine action, which was still very feeble, and suggested the following points for consideration: viz., that if the parts at the brim of the pelvis were incapable of passing through it in their present state, they would become so impacted under uterine action as to render operative interference much more difficult, if not impossible; but that, if this disproportion did not exist, uterine action would be a most important agent in completing the delivery.

"After allowing the woman about two hours to recover herself, I again visited her with my father and Dr Bernard, when we agreed that it was better to defer the use of ergot for the present, owing to the entanglement of the feet of the second child about the first, and the consequently greater probability of impaction. I now succeeded in passing the hook over the second shoulder and drawing the arm down, but this had no better effect than the descent of the first; the legs of the second child, which had before surrounded the body of the first, now embracing the neck with a firm hug, and no further progress could be made. I was again obliged to trespass on Dr Harvey, who immediately accompanied me, and devoted all his skill and energy to the case. Traction on the child in its present position appeared utterly useless, while every effort to alter its position, and turn its abdominal aspect towards the mother's sacrum, or to free its neck from the grasp of the second child's legs, though modified in every conceivable way, also failed. At length Dr Harvey having passed his hand along the back of the child, and got his fingers well over the shoulders (a manipulation which had several times been attempted before ineffectually), he succeeded by a strong effort in bringing them down into the pelvis, through which they then advanced readily, and soon passed the perineum, followed by the head. And now there could be no longer any doubt about the cause of the previous delay and difficulty, as the child hung from the vagina by the upper part of the abdomen, showing evidently that this part was adherent to the other child.

"Nothing further remained to be done than to see that the second child was advancing in a position favourable for delivery; and Dr Harvey, having discovered on examination that the arm was presenting, immediately turned, and the labour was completed in a few minutes more. The uterus now contracted well under the influence of a dose of ergot, and the placenta was expelled in a short time; it and the cord being single, and similar in every respect to those of an ordinary child.

"The children (both females) proved to be united by the abdomen from the lower edge of the thorax to about the umbilicus. There was an extensive laceration of the abdomen at the lower part of the united portion, from the violence used in dragging on the first child. From this the intestines protruded, and the cavities were seen to communicate freely, no appearance of a septum existing at the united portion. The insertion of the cord was rather obscure, in consequence of its having broken short, as already described, and of the lacerated state of the abdomen in its vicinity. On a subsequent and more careful examination, one umbilical vein could alone be found, and, on injecting this, the wax flowed readily into the right auricles of both hearts, showing that this vessel continued single until after its entrance into the common abdominal cavity. I next proceeded to examine the intestinal canal, and, commencing with the stomach of one child (which we may call No. 1), to which I ascertained it belonged, by passing a bougie down the œsophagus into it, I, with some difficulty, followed the course of the intestine, until I reached to about the junction of the jejunum and ilium. Here it suddenly dilated into a pouch at least four times the size of the stomach. It was somewhat triangular in shape, and from the opposite angle of this the small intestine was again prolonged, and could be distinctly followed till it terminated in a cæcum, passing on to the colon and rectum; but, strange to say, they were those of the other child, or No. 2. A second examination, made with great care, proved the correctness of the first. I had, in both examinations, found some obscurity about the commencement of the canal; as, at a short distance from the stomach, it apppeared to be entangled in, or adherent to, another fold; but I was quite satisfied that I had followed it correctly.

"I then commenced with the stomach of child No. 2, and, after finding a somewhat similar obscurity near the commencement of the canal, distinctly followed it into the same dilatation already referred to; and, as the intestine which I had now traced into it from the stomach of No. 2 proved, on examination, to be the same which I had before followed from No. 1, it was evident that union had occurred higher up between the two alimentary canals, and that they had then continued as a common tube into the dilated portion. Accordingly, a close examination showed that the two duodena ran towards one another, and, uniting, appeared to connect the stomach by a tube of about three or four inches long; and from near the centre of this a common jejunum passed off, and descended, as already described. On again examining the dilatation of the small intestine, it appeared that the third angle of the triangle was prolonged into a sort of infundibulum, and from this could be distinctly traced what appeared at first to be a mere thickening of the edge of the mesentery; but, after following it for about three inches, it began to assume more the appearance of an intestine, and, about two inches farther on, it had become a well-formed ilium, which again passed on to the cæcum, colon, &c., to terminate in the anus of child No. 1, or that with whose stomach we first commenced. The livers were so united by their right lobes that they could not be separated into two distinct organs."

The Author then makes some observations on the mode of development of double monsters; he believes that they originate in a single embryo.

We extract from the same journal the following *Case of Phlebitis*, by Professor O'Connor:

"There is scarcely any subject in medical science on which greater light has been thrown by the researches of modern pathologists than that of phlebitis. The advantages of these discoveries have passed beyond the point they were intended to elucidate, by awakening attention to the doctrines of the humoral pathology, which had passed into unmerited oblivion. Chemical analysis and the microscope have given positive proof of the humoral origin of many diseases discarded previously as mere conjecture.

"The true nature of phlebitis was scarcely known to the world before the writings of John Hunter appeared. And even he had but imperfect ideas on the subject, confined to the primary effects of inflammation on the diseased veins. The opinions of his pupil, Abernethy, were still more vague. According to him, the manner in which phlebitis destroyed life was by the extension of the inflammation to the lining membrane of the heart. As late as 1818, Mr Travers speaks of the innocuous quality of pus when mixing with the blood; asserting that all the evil in such cases was produced by the diffuse inflammation of the veins. The collections of pus found in various parts of the body were supposed to be caused by a metastasis of the pus originally secreted in the diseased veins. The discoveries recently made, that pus globules are too large to pass through capillary vessels into the general circulation, rendered necessary another explanation of these purulent deposits, which was readily afforded by assuming that every pus globule, entering the liver, through the portal veins, or the lungs through the general circulation, becomes a centre of suppurative inflammation in these organs; and, accordingly, that superficial abscesses cannot appear in cases of phlebitis without the lungs being first in a state of suppuration. This opinion is put forth in the following words by Simon, in his Lectures on Pathology: 'I have never seen scattered abscesses in the course of the aortic circulation, except where the lung itself was in a state of suppuration.' A similar opinion, founded, I believe, more on theory than fact, is held by the majority of writers. The following case will, I think, show that there are some exceptions to this general rule; it will be necessary subsequently to see how far these cases can be reconciled with the physiological facts above referred to:—

"Mrs M. was attended in her confinement by a physician in this city. The labour was natural, but some fever, with tenderness over the uterus, arose some days after. She had frequent rigors, with heavy perspirations. I was called to see her about three weeks after her confinement. The tenderness in the abdomen had entirely ceased, but the fever still continued, and abscesses presented in various parts of the body, along the legs and thighs, in the neighbourhood of the joints, and on the abdomen. I am quite sure that during four weeks that I attended her, I opened not less than twenty abscesses. They had all this character in common, that they formed rapidly, and healed as rapidly when opened. All the cases of phlebitic abscesses I observed had this peculiarity. The foregoing was, I am sure, a case of blood-poisoning from some obscure inflammation of the uterine veins: still, there never was the least trace of inflammation or suppuration in the lungs; neither cough, pain, dyspnœa, nor any of the stethoscopic phenomena indicative of such state. Indeed, her perfect recovery would almost preclude the idea of the existence of so formidable a disease.

"Mary Murphy was admitted into the Mercy Hospital some weeks after her confinement, suffering from phlegmasia dolens, with the usual symptoms. After some days, the swelling in the leg subsided, but abscesses formed in rapid succession, which left no doubt of their phlebitic origin. Hectic fever ensued, and the patient gradually sank from exhaustion; but at no time was there discovered any suspicion of disease in the lungs, though carefully looked for.

"About three months since, I was called on to attend a young man who was said to be in fever. He had a quick pulse; heat of skin; great prostration, preceded by rigors; and I should have left the case, believing the diagnosis made before my arrival to be correct, had the patient not alluded to a slight hurt on his shin, which he stated he had got some days before. On looking at the seat of injury, I saw an unwholesome ulcer discharging a small quantity of ichorous pus, and, proceeding from it towards the groin, a number of red lines. This showed me at once that the fever was only symptomatic of venous inflammation or purulent absorption from the wound. On the following day the thigh was extensively swollen, and most tender to the touch, resembling in all respects a case of phlegmasia dolens. He had, besides, severe pains through the abdomen, with retention of urine, which had to be drawn off for several days. Abscesses soon formed on the thigh, the leg, and the abdomen, on the opening of which the swelling of the thigh and the pain subsided. However, the fever continued, and in a few days the other leg and thigh became swollen, and went through nearly the same course. The constitutional symptoms were very severe, and at times little hope was entertained of his recovery, which, however, ultimately took place. In this case, too, we had proof of extensive venous inflammation, without the slightest trace of pulmonary disease. If, then, pus globules cannot pass through the lungs into the general circulation, how are we to account for the facts which I have brought forward? This may be done in two ways: first, that pus globules may be so broken down before reaching the lungs, that their nuclei may pass into the general circulation, and produce such a tendency to coagulation of the blood as must produce inflammation, and consequent suppuration; or fibrine, altered by the inflammatory process, but not converted into pus, may take the same course, and produce the same effects. From this we may come to the conclusion that there are other forms of blood-poisoning, the result of inflammation, besides pyemia. This conclusion affords an explanation of many anomalous cases of puerperal fever, which frequently end in death without suppuration being discovered in any part of the body. Might not this fever be the result of some foreign body, not pus, being absorbed by the uterine veins? Many cases of phlegmasia dolens would admit of a similar explanation, though some of them are manifestly the result of adhesive inflammation in the veins. In one such case, many months after recovery, I found the superficial veins of the abdomen completely obliterated, and converted into hard, cord-like substances. I may also instance hydrotic fever, which sometimes ends in manifest pyemia, and sometimes kills by the simple influence of irritative fever. I have some hesitation in adducing as similar instances the eruptive fever sometimes met after confinements, and called puerperal scarlatina. I cannot imagine that, of all contagious diseases, scarlatina should be the only one met under these circumstances. Why not puerperal measles, small-pox, typhus, &c.? They are at least as contagious as the former; and one of them, small-pox, more likely to occur at the late period of life in which this disease occurs. The cases of this fatal disease which came under my notice were persons in whom scarlatina had occurred earlier in life, and we know how rarely a second attack of this disease is found in the same individual. I may also mention the great fatality of puerperal scarlatina, as distinguishing it from ordinary scarlatina, which is occasionally very mild. Without attempting to dogmatiza on the subject, I would simply suggest for future observation the possibility that this disease may be only a rash symptomatic of some uterine affection. If such should be found correct, it would remove from physicians the painful apprehension that they sometimes are the cause of inflicting a contagious disease upon those whom they profess to cure."

We quote from the 'London Medical Review' the annexed account of a case of *Cancrum Oris*, by Mr Richard Marley:

"On the 1st May, 1860, I was requested to see Ellen J——, a little girl, aged seven years. Upon my arrival, I found she had been rather ailing for some days, and the parents had (as is too often the case in country districts) applied to a chemist. He gave the child some syrups and powders, but as she got worse, I was sent for.

"She appeared to be suffering from a mild attack of infantile remittent fever. The stomach was in so irritable a state as to cause the almost instant rejection of food, whether solid or liquid, and the bowels were obstinately confined. The parents had administered two or three doses of castor oil and senna tea, with no effect, save vomiting.

"I prescribed:

Calomel, one grain
Potas. Sulph. gr. vij, as a powder,

but which was immediately rejected.

"The incessant vomiting was of so debilitating and harassing a nature that I determined, if possible, to allay it. I prescribed:

Tinct. Hyoscyami, ℥iss.
Acid. Hydrocyanic. gtt. vj.
Aquæ Piment. ℥iss.

A teaspoonful of this mixture every two hours was given and retained. This, and a cataplasm, one-half mustard and one-half flour, effectually stopped the irritability of the stomach. There was no abdominal tenderness, and only a slight soreness over the epigastric region, resulting from the application of the mustard. In all cases of constant and apparently irremediable vomiting (as in that of early pregnancy) I find great benefit from homœopathic doses, as far as regards quantity, of medicine or of nourishment. A teaspoonful every hour or two may fail to excite vomiting, when a tablespoonful may have a contrary effect.

"A little cold weak sherry and water was administered in teaspoonful doses, and was retained.

"Having by a strict inquiry ascertained that the bowels had been constipated for nearly a week, and fearing to cause a return of the sickness by administering purgatives, I administered an injection of

Ol. Ricini, ℥j.
Ol. Olivæ, ℥ss.
Decoct. Hordei, ℥j.
Tinct. Opii, ℥ viij.

"She retained it for about half an hour, when it came away ineffectually.

"May 3rd.—I gave her another injection, containing, in addition to the former,

Magnesiæ Sulphas. ℥ss.

"This acted thoroughly, and brought away a copious stool, containing hard scybalæ and thinner fœtal matter of a highly offensive nature. The sickness being allayed, and the bowels well opened, I thought sufficiently light of the case to tell the mother to let me know how she got on, not intending to put her to the expense of any more daily visits.

"May 8.—Mrs J—— called and said the child was about the same in herself, but she fancied 'her mouth was a bit sore, as her right cheek was a bit hot, and upon her gums and tongue were little white spots, like she had seen in infants with the white mouth.' These were about her words. I sent her some powdered Borax mixed up with Bol. Armen., honey, and a little Tinct. Benzoin. comp.

"May 9.—I saw the child, and to my surprise, I may even add consternation, I found that the disease Cancrum Oris was unmistakably established, and gangrene rapidly spreading.

"Apthæ were still present: the gums were spongy, bleeding, and ulcerated; the inside of the right cheek, as far at least as I could see, presented one uniform, dark brown, gangrenous surface. The teeth were loose, and the discharge and breath very offensive.

"In the centre of the cheek, externally, could be felt a hard lump, that might be compared to a kernel, of a livid colour. The mouth could not be closed; and the saliva, vitiated in quality and increased in quantity, mixed with blood and sanies, dribbled continually away. Altogether the child presented the picture of a dreadful and rapidly-progressing fatal disease.

"The treatment amounted almost to *nil*, the child resolutely refusing all internal applications. But such was the extent, depth, and surface of the gangrenous and sphacelated surface, that Acid. Nitric., or Argent. Nitras., or, indeed, any other powerful caustic, would, I feel assured, have never penetrated the mass. She washed out her mouth occasionally with a deodorising wash. Eating was impossible, and drinking almost as impracticable.

"May 10.—Tenderness of the abdomen: relaxed motions, and other symptoms of entero-colitis, now appeared.

May 11.—In the angle of the mouth, a dark sphacelated spot became manifest; this rapidly spread, the livid and new dark 'kernel' on the cheek ran into it; and on the 12th, the whole cheek, internal and external, was thoroughly gangrenous; the teeth were visibly loose, and the sphacelated parts were covered with a slimy thin ichor, alike unsightly to the eye and offensive to the nose.

"May 13.—The motions passed away under her, slimy and bloody. Low muttering, rambling delirium was now constant. The disease, more gradually but surely, seemed involving the deeper and harder structures; and things went on in this state, getting from worse to worse, until early in the morning of the 16th ult., when death put an end to her sufferings.

"*Remarks.*—This case presents one or two points worthy of remark.

"Independently of any peculiarity, Cancrum Oris is happily so rare a disease, that a well-authenticated and well-marked case is worthy of record.

"Had the previous and slight illness before anything to do with it?

"For it has been known to follow fever before.

"Was it cause or effect, or a mere coincidence of a fatal disease, seizing upon an already debilitated constitution?

"Some months ago I had attended this child with mild scarlet fever, and beyond an incipient and transitory sore throat, she had had a good recovery.

"Cancrum Oris is usually found amongst the children of the poor, where they are ill-fed, poorly-dressed, and allowed to revel in uncleanliness and filth, sleeping in badly-ventilated, overcrowded rooms. Here was a child of respectable parents, living in an open and beautiful country, well-fed, well-clothed, well-cleaned; and yet this disease appeared, and rapidly ran its fatal course.

"Its extreme rapidity and the apparent insidiousness of its approach are remarkable. On the 3rd, I left her convalescent. On the 9th, I found a hopeless case.

"The state of the bowels was a deviation from the course usually observed in this disease. Obstinate constipation prevailed at the outset; diarrhœa and entero-colitis being almost always the complication from the first, and frequently before any local affection of the mouth is observed. Pain over the abdomen and muco-purulent bloody stools occurred about five days before death, and showed that the affection of the mucous membrane, commenced above, was continued downwards throughout the whole alimentary canal.

"Pneumonia, a most frequent complication, was absent.

"The only dose of mercury given was immediately rejected. This is worthy of remembrance; for a gangrenous affection of the mouth from the use or abuse of mercury, very much resembling Cancrum Oris, has been known to result from the exhibition of seven grains of calomel, and, according to Dr Stokes, even of gr. iss.

"The primary stage of inflammation and of ulceration was over before I saw her; on the 9th it was gangrene.

"Most authors, I believe, agree that it is not contagious. A sister of the patient, very imprudently, was given and allowed to suck a piece of barley-sugar from the mouth of the diseased child. As yet, I have not seen (nor indeed do I expect to see) any symptoms of taint.

"In conclusion, the points most worthy of consideration in this case are, the previous obstinate constipation, the insidiousness of its approach, its rapidity of progress, and the absence of pneumonia, either primary or secondary, which is present, according to Rilliet and Barthez, in eighteen out of twenty cases."

M. Claude Bernard's Lectures on *Experimental Pathology* are continued in the 'Medical Times and Gazette.' The Lecturer treats this week of the *Gastric Juice*. He observes, with respect to its properties:

"Although its chemical composition slightly differs in various animals, the gastric juice is constantly endowed with a strong acid reaction, a fact established towards the beginning of the last century by the ingenious experiments of Réaumur. This property of the secretion persists throughout the entire scale of being, and comparative anatomists have often been enabled in consequence to determine the precise seat of the stomach in doubtful cases, the reaction of all the other parts of the digestive apparatus being neutral, or even decidedly alkaline. The use of coloured tests enables therefore the observer to point out with perfect accuracy that portion of the intestinal tube which corresponds to the animal's stomach. In certain fishes, for instance, no modification whatever in the shape or size of the alimentary canal corresponds to the place which the organ occupies; so that, without the use of coloured tests, to discover its position would be altogether impossible.

"But the glandular cells, which pour into the cavity of the stomach this powerful solvent, are not collected into a conglomerate mass, but disseminated over a large surface. In former times, the inventive powers of anatomists had been strongly tasked for the purpose of discovering the organ which produces the gastric juice; and, among other viscera, the spleen had been invested with this property, but it is now universally acknowledged that the small tubular glands, which the mieroscope exhibits in the mucous membrane of the stomach, are, in reality, the only source from which this fluid is derived. But how is this to be experimentally demonstrated? The secretion of these little bodies cannot, as in the case of large conglomerate glands, be collected by means of a tube introduced into the excretory duct, and afterwards analysed. Now the mucous membrane which contains them possesses at the same time a considerable number of small mucous follieles, the structure and properties of which are entirely different from those of the above-mentioned glandulæ; direct experiments are, therefore, evidently required to settle the question. The first satisfactory solution of this difficulty is due to Prévost and Leroyer, of Geneva. These gentlemen have proved, by the following experiments, that the pyloric portion of the stomach alone enjoys the property of secreting the gastric juice. The stomach is opened in a living animal by an incision made upon its anterior surface, the abdominal walls having been previously divided. Its inner surface is then gently wiped dry with a fine sponge, imbibed with a weak alkaline solution, care being taken, of course, not to rub off the epithelium; lastly, blue litmus paper is introduced into the cavity, the wound is closed, and after the lapse of a few hours the animal is killed. It will then be found in making the autopsy that, towards the pyloric extremity of the organ, the blue test paper has turned red, while in the other portions of the cavity it has retained its primitive colour, a result which proves that the pyloric portion of the stomach containing the little tubular cells previously alluded to is the real seat of the gastric secretion.

"The experiments may be repeated on various kinds of animals, and invariably leads to a similar conclusion. Thus, in the horse, the pyloric portion of the stomach, and in the Ruminantia, the *red* or pyloric portion of the apparatus, are alone endowed with the property of secreting this fluid, as the coloured tests sufficiently evince. We may therefore consider it as an incontrovertible truth, that towards the pylorus alone is the gastric juice produced.

"But the secretion of these little glands is an intermittent one, in man as well as in the lower animals. Dr Beaumont states that in the case of his Canadian patient, the fluid only made its appearance when food was introduced into the stomach; but as soon as the digestive process was over, no secretion whatever took place within the gastric cavity until the patient had made another meal. In the same manner, when a canula has been introduced into a dog's stomach, not a drop of liquid escapes, provided the animal has been previously kept fasting; but as soon as it begins to feed large quantities of gastric juice are at once seen to flow from the outer orifice of the tube, and the result may be obtained by merely showing the animal its food, as in the case of the salivary glands. In the dog which we exhibit here, the stomach is at present in a state of rest; but the sight of food will immediately stimulate the physiological activity of its glandular elements.

"(The experiment is performed, and perfectly succeeds: a piece of meat being brought in, the gastric juice immediately flows in abundance from the open tube, before the animal has begun to feed.)

"You perceive gentlemen, that, as in the case of most other glands, the process of secretion is not continually going on in the stomach. During the interval which separates one meal from another, the mucous coat is lined with a thick layer of greyish epithelium, and its reaction is alkaline; but as soon as the digestive process commences, it swells, becomes ingested, and grows red; the epithelium falls off in scales, and the gastric juice appears on the inner surface of the stomach, in the same manner as perspiration on the skin. It seems probable that some similar process takes place in all glands during the period of rest. Saliva, for instance, when it begins to flow, contains a considerable proportion of epithelium at first; but the liquid soon becomes transparent, and contains only a few epithelial cells.

"There exists a remarkable difference between the gastric juice and these secretions we have already studied, with respect to the substances eliminated from the economy by the respective glands, after having been introduced into the vessels. We have shown you, for instance, that prussiate of potash and the salts of iron, in general, were not admitted into the salivary secretion; now, the reverse takes place in the case of gastric juice. When prussiate of potash is injected into an animal's veins, if one of the salts of iron is introduced into the stomach, the mucous membrane soon assumes a deep blue colour in its pyloric portions, while digestion is taking place: the two substances having been brought into contact at the orifices of the tubular glands which secrete the digestive fluid, Prussian blue has been formed on the very spot. The same result may be obtained, but with much greater difficulty, by reversing the experiment, and injecting the salts of iron into the veins, while the prussiate of potash is taken by the mouth; and, lastly, when these two substances are separately injected into the vessels, the same effects are still observed; the reaction does not take place as long as they are contained in the blood, but is produced immediately after they have been set at liberty by the process of elimination.

"In making the above-mentioned experiment, I had entertained the hope of discovering the precise seat of the gastric secretion: the two substances being introduced into the circulation on distant points, I had expected to find the Prussian blue which results from their combination contained in the very glands which separate them from the blood; but, in this respect, my expectations have not been realized; for on examining, under the mieroscope, the mucous membrane in which the reaction had taken place, I found that the ferrocyanuret of iron was deposited on its surface, and not within the cavity itself of the secreting tubes.

"We have just stated that the secretion is an intermittent one, and that this is the case in all animals; but how can the fact be proved in rabbits, and other Rodentia, the stomach of which is never empty? The inspection of the urine allows us, by an indirect method, to arrive at this conclusion; for, in all herbivorous animals, this fluid offers, during the process of digestion, an alkaline reaction, and becomes acid as soon as the process is over: in the Carnivora, the reverse takes place; and this difference results merely from the nature of their food; for dogs exclusively fed upon potatoes, and other amylaceous substances, acquire in this respect the properties of herbivorous animals: their urine grows acid while the digestive organs are at rest, and alkaline as soon as they enter into an active state; while in rabbits, exclusively fed upon meat, the urine becomes, on the contrary, entirely similar to that of the Carnivora. If, therefore, one of these animals is examined when fed as usual upon vegetables, it will be found that, after a long period of abstinence (twenty-four hours, for instance), the urine becomes quite acid; we are therefore entitled to believe that digestion has been awhile suspended, although the mucous coat of the stomach remained perpetually in contact with portions of undigested food. But in certain cases of disease, the natural conditions of the gastric secretion being altogether perverted,

an uninterrupted flow of liquid takes place. We have informed you, in a previous part of this course, that the stomach often eliminates certain bodies which for various reasons can no longer escape through their usual channels. Prévost and Dumas ascertained, many years ago, that when both kidneys were removed in a dog, several days would elapse before it was possible to prove the existence of urea within the blood by means of chemical tests: another, and a different mode of elimination had therefore been provided for this substance; but these gentlemen had made no attempt whatever to give an explanation of the fact, when I discovered unequivocal signs of the presence of urea and salts of ammonia in the gastric juice of dogs which had recently been deprived of both kidneys. It therefore appears that in this part of the body does the elimination take place during a certain lapse of time; and the animal's appetite does not diminish under these circumstances, nor is digestion impeded, but when the stomach can no longer perform its office in this respect, the noxious substances pass into the blood, and the symptoms of uræmia make at last their appearance."

Dr C. D. Doig contributes to the same journal an article headed *The Forceps and Perforator Compared.* After briefly relating two cases, and reciting some statistics by Dr Ricker of Nassau, and Dr Davis of London, the writer goes on to say:

"The preceding data indicate that deficient pelvic space is one common condition requiring operative procedure; in what cases, then, of pelvic contraction may the forceps be applied with success, and in what must the perforator be resorted to? It is difficult to come to a definite conclusion on this point, as each case requires to be considered individually. In the instance detailed, craniotomy was performed in consequence of disproportion between the child's head and the pelvis, attended by comparative feebleness of the pains. In many cases, however, requiring this operation, or the less serious one, the forceps, the pelvis is distorted, as well as of unequal size. Although it is impossible to lay down rules applicable to every individual instance, we can come to conclusions which admit of general application. The conjugate diameter of the normal pelvis varies from four inches at the brim, to four and a half inches at the outlet. Dr Simpson, of Edinburgh, used to lay down the following rules: that the forceps could be applied if the conjugate diameter was three and a quarter inches, and that embryulsio was to be adopted when the conjugate varied from one and three-quarter inches to three and a quarter inches.

"We come next to inquire, what is the frequency of these operations compared with other obstetric operations, and with midwifery practice in general; and what is the mortality attending the operations? The results of the statistics of different authors are more various than is desirable, and are exhibited by the following figures:—

		Labours.	Forceps.	Proportion.	Craniotomy.	Proportion.
				1 in		1 in
Dublin	Clarke	10,199	14	728	49	248
,,	Collins	16,654	27	617	118	141
Paris	Baudelocque	17,383	31	561	6	2,898
,,	Lachapelle	22,243	76	293	12	1,854
,,	Boivin	20,517	96	214	16	1,282
Vienna	Bon	9,589	35	274	13	737
Heidelberg	Naegele	1,711	55	31	1	1,711
Berlin	Kluge	1,111	68	16	6	185
Dresden	Carus	2,549	184	14	9	283
Berlin	Siebold	2,093	300	7	1	2,093
London	Davis	7,302	6	1,217	9	811
Nassau	Ricker	304,150	4,223	72	165	1,843

"The following figures give more minute particulars with reference to the frequency of these two operations in British Midwifery:—

		Forceps in			Craniotomy in	
Simpson	1	472 cases.	1		1,417 cases.	
Lever	1	518 ,,	1		186 ,,	
Churchill	1	546 ,,	1		149 ,,	
Ramsbotham	1	611 ,,	1		805 ,,	
Collins	1	617 ,,	1		141 ,,	

"It may therefore be with safety inferred that in British Midwifery forceps cases occur once in 550 births, and craniotomy once in 530 births.

"With regard to the mortality attending forceps cases, Dr Ricker mentions that out of 4,223 instances 93 women died either during, or soon after, the operation, and 684 children were still-born. Hence 1 woman out of 45$\frac{3}{93}$ deliveries by the forceps died, and 1 child out of 6$\frac{1}{8}\frac{9}{4}$.

"Dr Ricker also states the results attending the breaking up of the fœtus, which may be arranged under two divisions:—

"*Perforation*, 143; proportion, 1 in 2,126; lived, 88; died, 35; no information, 20.

"*Embryotomy*, 22; proportion, 1 in 13,825; lived, 16; died, 6.

"In the course of the preceding remarks have been considered—1. The mode of using the forceps; 2. The method of practising craniotomy; 3. The circumstances demanding the performance of these two operations; 4. The diameter of the pelvis that admits of the use of the forceps or the performance of craniotomy; 5. The comparative frequency of the two operations; 6. The success attending each. The investigation might be profitably carried to a much greater length, but the object of this paper has been rather to associate this statistical inquiry with actual cases, than enter into minute details."

Assistant-Surgeon Chapple communicates a report on *Sudden Mortality from Coup de Soleil.* We quote the following:

"To what cause or causes was the mortality attributable? In enumerating the cause likely to be productive of mortality, I shall also draw a comparison as to Barrack Accommodation, Dress, Duty, Habits, &c. between the Battery and a detachment of the 4th Regiment stationed in Baroda at that time, and which (with the exception of one death) continued perfectly healthy. The strength of the Detachment was, non-commissioned officers and men, 171; the strength of the Battery, non-commissioned officers and men, 210. Now it has been seen that between May 27 and June 2, there were ten deaths, and almost half the Battery on the sick-list; the Detachment of the 4th Regiment during that period lost one man from *coup de soleil*; but the men were remarkably healthy, not the slightest increase of sick; on the contrary, there were fewer in hospital at the time than for some months previous.

"*Barrack Accommodation.*—The barracks are high, well-ventilated, and commodious, allowing an average cubical space of 12,000 feet per man. They were similar for the Detachment of the 4th Regiment and for the Royal Artillery.

"*Diet.*—No cause likely to affect the health of the men could be traced to the diet, as the rations were good, and were similar for the Detachment of the 4th Regiment and the Royal Artillery.

"*Dress.*—The head dress worn by the Detachment of the 4th Regiment and the Royal Artillery was the cap cover of equal thickness but of different colours; it would be sufficient protection against a morning or evening sun, the only one to which a soldier in cantonment is likely to be exposed, but against a mid-day sun it would be totally inadequate. The clothing light and loose, and alike except in colour for Detachment of the 4th Regiment and the Royal Artillery.

"*Duty.*—The duty performed by the Royal Artillery was more severe than that of the 4th Regiment, and the men were consequently more exposed to the sun. Five days out of the seven the Royal Artillery turned out for duty at daylight, and did not return until seven o'clock. In the evening again the men turned out to stables about half-past five o'clock p.m. The usual absence of the slightest breeze about that hour renders it the most oppressive time of the day.

"*Intemperance.*—The quantity of arrack consumed in the canteens of the Royal Artillery and 4th Regiment respectively having been ascertained, it was found that the consumption per man in the former was more than twice as much than in the latter.

"It will be thus seen that the Royal Artillery had more duty to perform than the 4th Regiment, and that the latter were of more temperate habits; in all other respects they were similarly situated. Of those who died, some were said to be free drinkers, and others hard drinkers. I have no doubt that when the nervous depression seized the men, many had resort to drink as a relief.

"The heat during the latter half of May was very oppressive, the thermometer registering an average of 106°; at four p.m., in the barrack-room, on the 1st and 2nd of June, it was 110°. The nights also showed a corresponding rise in temperature, the thermometer during that time at ten p.m. averaging 97°. Thus the continuous high temperature, and to a certain extent the exposure while at duty, especially evening duty, acting on men of intemperate habits, no doubt caused the mortality. The Detachment of the 4th Regiment, having no duty to perform at times, which compelled them to leave their barracks before they could do so with safety, and being of more temperate habits, they suffered less in proportion to the Royal Artillery.

"*Symptoms.*—The following symptoms are invariably present:—Severe headache, which is sometimes not mentioned, owing to drowsiness and stupid insensibility to pain; face generally pale. In severe cases the patient may become suddenly pulseless, but generally the pulse is quick and full; indeed, the pulse as a decided symptom cannot be depended upon, as it differs almost in every case. Skin intensely hot and dry, constriction of the chest, great debility. As the disease advances, the vessels of conjunctivæ become suffused, the pupil contracts, face pale or of a leaden hue, head and extremities cool, the rest of the body hot and dry, pulse weak, action of heart violent; the patient is with difficulty made to comprehend what is said to him; the act of deglutition is with much difficulty performed. I have seen the stage of coma frequently ushered in by vomiting. When the patient becomes comatose, the breathing is slow, laboured, and accompanied with loud moaning; the pupils are contracted to a point (though on one or two occasions I have seen them dilate for a few minutes, and again contract). The vessels of conjunctivæ are highly congested; pulse very irregular, action of heart intermittent. Skin intensely hot and dry, extremities cold, head cool; I have remarked a very peculiar pulsation of iliac and femoral arteries in every case of sunstroke which I have treated. Immediately preceding death, vomiting frequently occurs, the pupils dilate, respiration is performed in gasps, and not accompanied with the loud moaning before mentioned. The skin remains hot for some time after death.

"In the early stage of the disease, when the head is hot, skin hot, and the patient conscious, I cause cold water to be poured on the back of the head in a continuous stream, administer a brisk purgative, and give frequently-repeated doses of ammonia or brandy, according to the feeling of debility or depression present. If the head does not become cool, and the patient complain of severe headache, I apply a couple of dozen leeches to the temples, and, having cut the hair close, apply a cold evaporating lotion to the head, and counter-irritants to the extremities. As the disease advances, and coma sets in, I usually apply a blister to the back of the head, administer stimulants by enemata, apply strong mustard sinapisms to the calves of the legs and inside of the thighs, or have them rubbed with aquæ ammoniæ fort.; but I have seldom by these means succeeded in reddening the parts: hot water I have found much quicker and more effectual in action. The skin being always intensely hot and dry, I have tried cold sponging of the whole body, and with evident relief; but in most cases, immediately the sponging was stopped, the temperature of the skin again rose rapidly. I have wrapped patients in wet sheets, by which means I thought I might get the skin to act, but without any benefit. I think the chief reliance, in the treatment of sun-stroke, is to be placed in application of cold to the head, frequent administration of stimulants, and the application of counter-irritants to the extremities. The patients generally die worn out, and therefore stimulants should be persevered in to the last, in order to enable them to battle against the disease. I have saved a few cases which had advanced to the stage of coma; and I attribute the recovery to the frequent exhibition of stimulant enemata, assisted, of course, by other means. There is a failure of nervous energy from the commencement of this disease, and our chief endeavours ought to be directed in supplying this defect.

Post-mortem Appearances.—I have never seen satisfactory evidences to account for death in any of the bodies which I examined. On one occasion I met with serous effusion to the extent of half-an-ounce at the base of the brain. The vessels of the membranes of the brain, and those of the surface of the brain itself, I have occasion-

ally found congested, but never highly so; on cutting into the substance of the brain, I have always found it quite natural. In those cases not treated by the application of leeches to the head, the scalp, on being cut into four or five hours after death, bled profusely. On one occasion more than twenty ounces of blood was thus poured out. The kidneys were unusually highly congested. The other viscera presented no changes worthy of note."

The 'Lancet' opens with Dr Brown Sequard's Lectures on *Paralysis of the Lower Extremities*. We extract the Lecture:

"The very striking symptoms of myelitis which we have described do not always exist in a very marked degree. According to differences in the seat of inflammation in the spinal cord, there are great differences in the intensity of the symptoms, and, still more, some of them may be missing. When the grey matter of the spinal cord is the seat of the inflammation, all the characteristic symptoms exist, and to a notable degree; but in those rare cases in which the inflammation is limited to the white columns of the spinal cord, there is a marked difference from the preceding kind of myelitis. If the posterior columns be the seat of inflammation, the symptoms are much less marked, but they all exist. When the disease is in the anterior columns, there is no anæsthesia, and the morbid sensations referred to the paralysed parts of the body hardly exist. We will return to this subject when we speak of the paraplegia due to pressure upon the spinal cord by a tumour, a displaced or broken bone, &c., and we pass now to the history of paraplegia due to a chronic meningitis.

"*Chronic Meningitis.*—The paraplegia due to this cause presents several characteristic features, of which we will say but very little, on account of the usual facility of diagnosis. These features are the following:—

"1st. Pain usually of a rheumatic character, and more or less diffused along the spine. Generally there is no great increase of this pain when pressure is applied on the spinous processes, as in cases of myelitis; while, on the contrary, every movement of the spine forward, backward, or laterally, increases the pain, sometimes to a very great degree.

"2nd. The nerves originating from the part of the spinal cord where the meninges are inflamed are the seat of acute pain, which is very much increased by mechanical causes. The sciatic nerves, for instance, when meningitis exists in the lower part of the spine, seem to be the seat of very great pains, which are much increased when the lower limbs are moved. When inflammation is confined to the part of the membranes at the place where the nerves of the upper limbs originate, the movements of these limbs cause great pain.

"3rd. There are frequent, and in some cases constant, spasms in the muscles of the back. Those spasms which render the spine almost immovable are produced or increased when an attempt is made to move the trunk. When they exist in the cervical region, they bend the head backwards, just as in tetanus.

"4th. In cases of meningitis, the degree of paraplegia may vary from the very slightest to the most complete. Sometimes a slight paraplegia increases and then diminishes rapidly, owing to rapid changes in the quantity of the cerebro-spinal fluid or to the degree of congestion that accompanies the inflammation of the meninges.

"5th. Anæsthesia is very rare in spinal meningitis. Sometimes there is a real hyperæsthesia, or at least a morbid sensibility and an increased susceptibility to reflex movements.

"6th. A curious symptom is a spasm of the sphincter of the bladder, which prevents the evacuation of the urine. In some cases this spasm is followed after some time by a paralysis of the sphincter.

"These symptoms are sufficient to characterise meningitis in a chronic and even in a subacute state. We will say a few words more hereafter on the diagnosis of this affection.

"*Congestion of the Spinal Cord and its Meninges.*—Several of the symptoms which coexist with paraplegia, in cases of myelitis or meningitis, are often observed in cases of simple spinal congestion, as shown by Ollivier d'Angers, in his important work on the spinal cord. This affection is frequently produced in cases of suppression of the menses or of the lochiæ, and of disease of the liver and other abdominal organs in which there is some obstacle to the return of blood from the spinal cavity. The paraplegia caused by excesses of sexual intercourse very often depends upon a congestion of the spinal bloodvessels. It is very rare that this congestion exists without an increase in the amount of the cerebro-spinal fluid, so that two causes then coexist to produce the paralysis of the lower limbs. The symptoms which characterise a spinal congestion are the following:—

"1st. Formication, alternating with numbness, especially in the beginning of the affection. The skin of the toes and fingers are the principal places where formication appears, but it often exists in various portions of the skin in the paralysed parts.

"2nd. Only a slight pain in the spine, hardly increased by pressure.

"3rd. Frequently a morbid increase of sensibility, even when there is numbness.

"4th. In many cases the power of moving the paralysed lower limbs is much greater when the patient lies down than when he stands up, which is due, however, not to the difference in the degree of congestion, but to the cerebro-spinal fluid, the amount of which in the lower part of the spinal cavity is greater when the patient stands up than when he lies down. On the contrary, the congestion of the spinal bloodvessels increasing when the patient is lying down, especially when he lies on his back, it is observed that the degree of paralysis is notably increased after a night's rest, when the patient first gets out of bed, and tries to stand on his feet and to walk. The fact that the degree of paralysis is always greater then than in the course of the day, when the patient does not lie down in the day-time, is one of the most important symptoms of spinal congestion.

"5th. The bladder and the rectum, and their sphincters, are usually more paralysed in this affection than in cases of paraplegia due to most other causes.

"6th. An ulceration upon the sacrum or nates is not rare in this affection.

"7th. Slight spasmodic movements are sometimes observed in some of the paralysed muscles.

"8th. It is usually difficult, and very often impossible, to produce reflex movements in the lower limbs.

"9th. Usually the paralysis is not limited to the lower limbs: when it begins in them, it rapidly extends to the upper limbs, and to some of the respiratory muscles; and when it begins in the upper limbs, it quickly reaches the lower ones.

"One of our objects in presenting here the principal features of paraplegia caused by myelitis, meningitis, or a simple congestion of the spinal cord and its membranes, is to call attention to the analogies and differences presented by these three affections. Pressure, and therefore excitation, upon either the spinal cord or the spinal nerves, is the principal cause of the phenomena observed in these diseases. As already stated, the vital properties of the spinal cord are changed in myelitis; the grey matter, which normally has no excitability, becomes excitable, and acquires the same properties as a nerve of sensibility and movement; and all the effects of pressure upon such a nerve are observed. In fact, the spinal cord is then just like a large compound nerve, comprehending the various nervous fibres that originate from it, not only at the place inflamed, but also most of those fibres which proceed from the parts of the cord below the seat of the disease. In consequence of this new condition of this nervous centre, the causes of excitation developed in inflammation (pressure by effused liquids, &c.) produce the various phenomena belonging to the three principal kinds of nervous conductors existing in the spinal cord; and several effects are then produced which are also observed in meningitis and in spinal congestion, owing to pressure upon the spinal nerves. It is interesting to compare, as we will do, myelitis, meningitis, and spinal congestion as regards the phenomena belonging to these three kinds of nerves.

"1st. *Alterations of motor conductors.*—Paralysis and cramps are the results of excitations of these conductors. The degree of paralysis in meningitis and in spinal congestion is different from that existing in myelitis, on account of the mode of its production. In myelitis, the number of motor conductors submitted to alterations is much larger, and also the degree of excitation is greater, than in spinal congestion and meningitis; so that both the degree of paralysis and the frequency of cramps are greater in the first than in the last two affections. A pressure upon the spinal nerves in the narrow canals by which they pass out of the spinal cavity is the chief cause of paralysis in cases of meningitis and spinal congestion. This pressure being very variable according to circumstances, great variations exist in the degree of paralysis. The rigid spasm of the muscles of the back in meningitis seems to be due to a reflex action, as in tetanus.

"2nd. *Alterations of Conductors of Sensitive Impressions.*—It is extremely interesting to witness the variety of sensations referred to paralysed parts in cases of myelitis. All the sensations that we may have, in health, in the skin, muscles, and other parts, may then be generated in the cord itself, although they are felt as if they came from the skin, muscles, &c.; and it is well known that this fact may be observed even when the skin and other parts are completely deprived of sensibility. In cases of spinal congestion and of meningitis, not complicated with myelitis, the *referring* of sensations to the skin and other parts is almost null. It might seem strange that a pressure upon nerves of sensibility and movement should be sufficient to produce paralysis, with or without cramps, and not be able to generate those sensations which are so easily produced by a pressure upon the ulnar nerve at the elbow; but, as I have tried to prove eight years ago, nerve-fibres able to transmit sensitive impressions may or may not be excitable and able to give origin to sensations. In some parts they are excitable, in others they are not; and therefore the absence or slight degree of sensations referred to the skin, muscles, &c., in cases of meningitis, only show that the conductors of sensitive impressions, in their passage out of the spine, where they are subjected to pressure, are not excitable, or, at least, that they have but a slight excitability.

"3rd. *Alterations of Vaso-motor Nerves.*—It is not the place here to insist upon the distinction between the effects of a paralysis and those of an excitation of the vaso-motor nerves. We will only state that in the three affections we are now comparing, the most important feature is, that there are striking effects of excitation of these nerves. In myelitis, especially, these effects are very marked: the alteration in the urine, the formation of sloughs on the sacrum, the nates, &c., the serous infiltration in the subcutaneous cellular tissue, the rapid atrophy of the paralysed muscles, the dryness of the skin, &c., are phenomena that clearly indicate a great excitation of the vaso-motor nerves of the paralysed parts. In cases of spinal congestion and of meningitis, it is not rare to observe these alterations of nutrition, but they are usually to a less marked degree than in myelitis. One of the most interesting effects of excitation of the vaso-motor nerves in myelitis —*i. e.*, the alkalinity of the urine—does not exist in meningitis nor in spinal congestion. It is not rare in these three affections that, near a place where some effect of *excitation* of the vaso-motor nerves is observed, there are effects of *paralysis* of these nerves, such as a dilatation of bloodvessels, increased heat, and sometimes an abundant perspiration."

Dr Stephen Ward contributes to the same journal an analysis, in a tabular form, of 1,000 consecutive cases admitted into the Seamen's Hospital 'Dreadnought,' the prevalence of the more important diseases being as follows: Fevers, 109; agues, 102; rheumatism, 97; scurvy, 96; bronchitis, 66; dysentery, 56; diarrhœa, 47; pneumonia, 41; anæmia, 40; paralysis, 24; diseases of heart, &c., 23; delirium tremens, 19; &c. &c. Dr Chuckerbutty contributes to the same journal a report of a case of *Abscess of the Right Kidney*, and Dr John Housley the following case of *Bronzed Skin*:—

"Henry ——, aged thirty-three, farm-labourer, unmarried, states that he had gonorrhœa in November, 1858; was ill in March, 1859, which he attributes to extra work during the lambing season. He consulted the late Mr Hammond, and was a week absent from his work. After resuming his occupation for two or three weeks (he cannot fix the exact time), he was again compelled to rest. He was now ordered to live as well as he could, and take cod-liver oil. On this occa-

sion, he was away from work for three weeks; then returned to his occupation, and continued until the end of June, since which time he has been unable to work. At this time I saw him. He complained of weakness, loss of appetite, nausea, occasional vomiting, pain at the epigastrium, and constipation of the bowels. The colour of his face and hands was brown, which I thought might be caused by the hot weather, for he was not confined to the house. About August, 1859, I considered the case might be one of Addison's disease. In the beginning of September, at my request, he was seen by a medical friend, who looked upon the case as hepatic disease. This gentleman advised him to have as good diet as he could procure; at the same time I had prescribed the tincture of the sesquichloride of iron. After this, I saw very little of him until Feb. 26th, 1860, when he sent for me. I was now informed that he had been at home during the last five months, and was becoming weaker. Appetite bad; at times feels sickly; complains of pain a little to the left of the navel; bowels rather constipated; stools dark-coloured; urine acid, lightish colour; pulse 94, soft and feeble; slight dulness on percussion below the left clavicle; sounds of heart feeble. The brown colour of the face and hands still remained; over the chest it is almost natural, but becomes much darker over the abdomen and thighs; that of the penis and scrotum is a dingy black, which he has noticed for the last two years. There is also a dark ring round the umbilicus. No odour is perceptible about the body of the patient. I attended him for a short time, and he felt somewhat better. I was again requested to see him on the 20th of April. My notes are as follows:—

"April 20th.—Bowels constipated; sickness; radial pulse scarcely to be felt. An ounce and a half of compound senna mixture to be taken immediately.

"21st.—Bowels acted twice; sickness continues. To take two minims of Scheele's hydrocyanic acid every four hours.

"22nd.—Takes scarcely any food, and what he does take is vomited. Continue medicine. To suck ice occasionally.

"23rd.—Has slept during the night; bowels constipated; there is nausea, but no vomiting. To take the compound senna mixture (an ounce and a half), with the addition of ten minims of chloric ether to each dose.

"24th.—Has taken only cold water during the last twelve hours; sickness subsided.

"25th.—Has vomited a large quantity of bilious matter.

"26th.—Takes only cold water; anything else is immediately rejected.

"27th.—Has slept during last night. Takes no food whatever. Died at half-past nine in the evening.

"I obtained permission to examine the abdomen. The post-mortem inspection took place twenty hours after death, Mr. Ward, of Wellow, kindly assisting me. Rigor mortis well marked; the body somewhat wasted. The colour of the skin was lighter over the legs and chest, and darkest on the penis and scrotum. The kidneys, portions of liver, &c., were sent to Dr Wilks, of Guy's Hospital, who has favoured me with a note from which I extract the following remarks:—'I have no doubt that yours is a genuine example of the disease (Addison's), and that the capsule which is now before me is a true specimen of the morbid change. It consists of a hardness of a fibro-albuminous tissue degenerating in parts, exactly as we have before seen. This tissue is smooth, firm, and of a pinkish colour. When examined by the microscope, it is found to be composed of nucleated fibre. In the midst of this are some yellow softer masses of the same in a state of degeneration, and resembling what is ordinarily called scrofulous matter. The skin shows the true pigmental change in a very beautiful manner. I have made a section, and the colouring matter is seen beneath the cuticle in the rete mucosum following the course of the papillæ, such as is met with in the skin of dark races of men. The kidneys, liver, and spleen are quite healthy. The liver has near the surface some cretaceous masses, which are probably the remains of some old tubercular disease.'"

THE MEDICAL ACT AMENDMENT BILL has been read a third time and passed. The Criminal Lunatic Asylum Bill has been read a third time.

ROYAL MEDICAL AND CHIRURGICAL.

TUESDAY, JUNE 26TH, 1860.

MR F. C. SKEY, F.R.S., PRESIDENT.

OBSERVATIONS ON THE MORBID ANATOMY, PATHOLOGY, AND DETERMINING CAUSE OF EMPHYSEMA OF THE LUNGS. By A. T. H. WATERS, M.R.C.P., Physician to the Northern Hospital, Liverpool. (Communicated by Dr OGLE.)

Although much has been written on the subject of pulmonary emphysema, there are yet many points in connection with it which require investigation. There is, perhaps, no disease the symptoms and physical signs of which are so readily explicable, from a knowledge of the structural changes by which it is accompanied, as this particular affection, and hence an acquaintance with the minute anatomy of the healthy lung tissue becomes of the utmost importance, in order fully to appreciate the morbid changes which take place.

(Here follows a brief description of the arrangement of the "ultimate pulmonary tissue.")

Pulmonary emphysema is of two kinds—1. Interlobular emphysema; 2. Vesicular emphysema. The second, or vesicular, is by far the most important, and will be alone considered. It exists in three forms, differing only in the extent to which they involve the lung.

1. *Partial Lobular Emphysema*, involving a few air-sacs, or at most only a single lobulette. This is not often seen as an independent affection; but in lungs which are the seat of the second form, it occasionally exists in small patches along the margins of the lobes. These patches resemble small vesicles, and when numerous have somewhat the appearance of a row of beads.

2. *Lobular Emphysema.*—This is the form most frequently met with. It involves one or more lobules in different parts of the lung, and is especially found along the margins of the base, the anterior border, and at the apex. It frequently exists in connection with phthisis, and occasionally with pneumonia. In this form it is easy to trace the divisions of the lung; the boundary walls of the lobules have not usually given way, and generally no interlobular emphysema exists. The air-sacs of a lobule are not necessarily all equally dilated, those at the circumference being most so. The emphysematous lobules may be seen projecting above the level of the lung, and in some instances they become developed into "appendages."

3. *Lobar Emphysema.*—This form involves the whole of a lobe, or an entire lung, or very frequently both lungs. It constitutes a very formidable affection, and often destroys life at an early period. The lung is much increased in size. The outlines of the lobules frequently cannot be distinctly seen, in consequence of the rupture of their boundary walls, and the production of interlobular emphysema.

In investigating the morbid anatomy of emphysematous lungs, the same methods of preparation were used by the Author as had been previously employed in the examination of the healthy organ—viz., injection, inflation, and desiccation.

With regard to the structural changes which take place in the disease, we recognise, in the early stages, a simple dilatation of the air-sacs, and a diminution in the height of the alveolar partitions. A further dilatation takes place, with more or less complete obliteration of the alveolar septa. This distension produces a divergence of the elastic fibres of the air-sacs, and is soon followed by a perforation of the walls themselves, so as to give in the advanced stage a perfectly cribriform appearance to the membrane of which the walls are formed. This is followed by rupture of the elastic fibres, a further distension of the air-sacs, with a general breaking-down of their walls, so that in the most advanced stages of the disease large cavities are found, traversed in all directions by membranous shreds or fibrous cords. The inner surface of the emphysematous lung tissue presents the same microscopic appearances as that of the healthy tissue.

In some lungs in which lobular emphysema existed, the air-sacs were found much distended, but no perforations existed; whilst in others, and especially where the disease was of the lobar kind, extensive perforations were found, with not more, and in some instances less, dilatation than in the former. This would seem to indicate some degeneration of tissue in the one case, which might be absent in the other.

The condition of the bloodvessels explains the anæmic appearance of the emphysematous lung. In the earlier stages, the capillaries of the pulmonary plexus are wider apart than in health; and as the walls of the air-sacs are perforated, and the latter more distended, the capillaries become ruptured and absorbed. The vascularity of the lung in a condition of advanced emphysema is very slight.

The bronchial tubes are usually dilated in old-standing cases of emphysema, their mucous membrane is pale, and there is increased development of the circular muscular fibres.

An important question in connection with emphysema is, whether the disease is preceded by, or attended with, any degeneration of tissue.

With regard to the existence of fatty matter in the emphysematous lung, a considerable number of specimens were examined with great care; and although in one or two instances indications of its presence were found, as a rule it was entirely absent. Dr Jenner has stated that a fibrous degeneration frequently exists. A number of specimens were examined to ascertain whether any alteration of this kind could be observed in the elastic fibres, as compared with those of the healthy lung. The results arrived at on this point were imperfect, and the question is left for future investigation. Some kind of degeneration is believed in many cases to exist.

With reference to the determining cause of pulmonary emphysema, the view that the disease is produced by expiratory efforts appears to the Author the most tenable.

Serious objections present themselves to the theory advocated by Dr Gairdner, that the disease results from increased distension, during inspiration, of one part of the lung, in order to fill the space previously occupied by a collapsed portion.

During inspiration, the chest expands to make room for the dilating lung; air is drawn equally to all parts of the lung, and is not driven by any external force to one part more than to another. It is difficult, therefore, to understand how an excessive quantity of air should find its way to any particular portion. If the chest must reach a certain expansion, it would rather appear that the entire lung would be everywhere slightly dilated, except where collapsed; or else that those parts nearest the collapsed portions would be most distended. Such parts, however, are not the most frequent seats of emphysema. Further, the lungs can undergo very considerable distension without suffering any injury. Although the lungs undergo equable pressure during ordinary expiration, this by no means proves that such is the case during acts of coughing; in fact, the contrary is true, as shown by Dr Jenner.

The conformation of the walls of the chest, and of the lungs, seems to render it necessary that the latter should undergo unequal compression during violent expiratory efforts with a partially closed glottis, and that the air should be driven first to those parts of the lungs where the walls are least resisting, and, secondly, to those portions which contain the least volume of air. The least resisting part of the thoracic walls is that which covers the apex of the lung; it consists of a membranous expansion, and plays no active part in the expiratory process. As a fact, we find, in coughing, that the lung bulges into the lower part of the neck. The parts of the lung which contain the least volume of air are the margins. These are out of the direct line of pressure which the lung undergoes in violent expiratory efforts, which are chiefly effected by the abdominal muscles, especially the recti. The contraction of these latter muscles, forcing upwards the abdominal viscera and the diaphragm, produces the greatest amount of compression at the base of each lung; the air is driven upwards in a strong current, which overcomes the current from the other portions, and these, instead of becoming emptied, remain forcibly distended.

The phenomena witnessed in M. Groux, probably seen by many of the Fellows present, may be adduced in support of the view that during coughing the lungs become distended in any part where the walls of the chest offer but little resistance.

Lastly, the cases recorded in a paper written by M. Guillot—in which what he describes as subpleural emphysema was found after death, preceded by long-continued and violent spasmodic cough—may be cited in favour of the expiratory theory of the production of the disease, a theory to which anatomical arrangement and physiological phenomena seem to point.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 1, 1860.

THE EASTBOURNE CASE.

The ignorance of the public of the simplest matters in psychological medicine has often been the subject of remark in this Journal. The capricious judgment with which Medical men are either praised or condemned in relation to their treatment of the insane, has, in numerous instances, tended to frustrate the timely application of remedial measures. Surgeons are unwilling to incur the risk of reproach, and the impeachment of their judgment or motives, when the mind of a wretched man is undergoing that insidious change which the vulgar eye cannot detect, but which is of critical exigency to the victim.

A recent case in which this ignorance of the evidences of disease has resulted in fatal consequences, calls from us a few remarks with the view of directing attention to the necessity of referring many of the forms of moral perversity or intellectual peculiarity to diseased conditions of the brain, and of thereby inducing a more considerate and watchful regard of these anomolous cases. The influence of cerebral organisation and disease upon the mind is received in general terms, but is scarcely recognised as a practical fact. We admit the principle, but deny or are blind to the inference in actual life. We know the latent danger to morals in a too easy and general application of the principle, but we do not apprehend that men's instinctive respect for their character and interests will ever suffer that peril to affect our moral obligations. An extreme jealousy of it leads, however, to mistaken rules of conduct, and to a barbarous behaviour towards individuals under circumstances where the tenderest care and gentlest moral suasion are necessary for the correction and guidance of their intelligence.

Our observations have been elicited by the report of the trial of Mr Hopley for the manslaughter of his pupil, the shocking details of which must be familiar to most of our readers. The pupil was characterised by slowness of mind, and, what seemed to be, a sulkiness of temper, which induced his master to beat him with severity as the only way he knew of sharpening his intelligence and making his heart cheerful. On one occasion, when the boy was unusually dull and failed in learning correctly a lesson in arithmetic, Mr Hopley took him into a room and privately flogged him with a skipping-rope. He then remonstrated with him with paternal tenderness; but the boy's mind remaining as obtuse as before, he dragged him up-stairs to his bed-room, and for two hour continued to beat him round the room with the rope, progging now and then with the end of a stick, whilst the boy cried with agony. During the intervals of the punishment, Mr Hopley prayed with the youth, to soften his obstinate temper; and at last the fountain of contrition was opened, and the pupil, we are told, wept upon the master's bosom and said his lesson. There is something shocking in this alternate flogging and praying, when we know that the result of it was the death of the child. Within a few minutes—or, as in all probability the truth, at the time when his head sank on his master's bosom—the boy's spirit left his tortured body. A Coroner's Inquest was held, and the after-death appearances, as interpreted by Mr Prescott Hewett, showed that the cellular tissue had been beaten into a jelly, that there were two holes in his body an inch deep which had been evidently caused by "jobbing" with a stick, the subcutaneous tissue was extensively ecchymosed, and the head was hydrocephalic.

Here, then, was the cause of the poor lad's mental sluggishness: the brain was diseased, and, apart from the horrible barbarity of the beating which terminated in death, the use of the stick was of all methods the very worst to cure it. We may be assured that, as a rule, flagellation is the resource of the idle or angry man. The human, like the equine mind, is best tamed by kindness. The stupidity of the pupil is only the excuse, and not the justification, of the cruelty of the master. In this particular instance physical punishment was in itself a crime against nature, and the brutality admits of no palliation.

It is remarkable that Mr Hopley was a lecturer and writer on educational and philanthropic subjects. His printed lectures were forwarded to us on various occasions, and, without doubt, to the other organs of the press, with the evident object of forcing his exertions into publicity. We cannot say that we regarded with much favour the pretensions that were set forth; yet it is not the less worthy of notice that a person who pretended to enlightened views on the subject of education, who ostentatiously claimed for himself the character of a philanthropist, and who was not without knowledge, should have been guilty of the atrocious conduct which we have described. Perhaps this overweening love of popularity is the key to his character. Let it be a warning to all fathers how they trust the authority of the cane out of their own hands. Let them keep it; for whilst we may hope that a father's heart will not let him abuse his right, we cannot rely with the same confidence on the forbearance of a stranger. Our schools, public and private, are not now the scenes of such cruelties, under the name of discipline, which formerly characterised them when Dr Busby wielded the rod at Westminster, and was the model for imitation by every rural pedagogue; but even now the cane is too frequently employed, and many children are barbarously flogged solely because the master is idle or ignorant.

The science of education will never attain perfection until it ceases to be a routine, and the peculiarities of the mental and physical constitution of each child be made the study of the educator. The spirit of all modern systems is to classify children according to their degree of instruction, to use them as mere parts of a machine—to merge, in short, the individual in the mass, irrespective of idiosyncrasy, taste, or powers;—a hard, mechanical spirit, qualified by iteration to give imitative speech to parrots, and in accordance with the mechanical genius of our age, but utterly unphilosophical and unnatural in relation to the essential functions of the educator. It is a spirit that breeds Hopleys, and, we hope, has found in this man its last expression.

SUMMARY OF THE WEEK.

A MEDICAL ESTABLISHED CHURCH.

Sir George Lewis is angry with the Union Officials throughout the country that they are not satisfied with the administration of the Poor-law Board, and accordingly, in the course of a debate last week on the question whether that Board should be continued in its functions for another five years—and in which, by the way, the Government sustained a defeat—exhibited a little more acrimony than befits his usually even and placid demeanour. He charged the Medical Authorities with a desire to institute a system which would legalise payment out of parochial funds for the Medical relief of persons not paupers—to set up, in short, a "Medical Established Church." If the system be a right one, we care not out of what funds the money comes, and Sir George may make the payments out of the Consolidated Fund if he wish to get rid of the anomaly; nor do we think the sarcasm will injure the soundness of the principle, that it is advisable to adopt some method by which poor persons should be enabled to obtain Medical relief without being declared paupers, and thereby degraded in their self-respect, and deprived of the right

and privileges of free citizens. Let Sir George Lewis think over this matter, and endeavour to emancipate his mind from the enslavement of the routine system in which his early years were trained. He is one of our rising politicians, and we hope that his views will expand as he rises.

THE PROTEST AGAINST SPECIAL HOSPITALS.

The contest between the General and Special Hospitals has reached its acme in the form of a Protest against the latter from some of the more important Members of the Medical Council, and the Physicians and Surgeons of the General Hospitals. We can easily imagine the indignation that some of our great London operators would feel at losing their "stone" cases, through the invitations which a Special Hospital for sufferers from these maladies would incessantly offer to the public. It is asserted that no cases of stone are ever sent away from the doors of our General Hospitals: if this be true, there can be really no need of a Special Hospital. We do not expect that Messrs Smith and Jones will be able to propound more instructive views of these affections, or delight us with more brilliant operations, than Messrs Fergusson, Erichsen, or Skey. The question of Special Hospitals does not, however, stand upon this limited basis; there is much to be said about it, which we shall reserve for another opportunity.

DEATH FROM CHLOROFORM.

One of those cases showing the imprudence of lay persons administering chloroform has recently occurred at Liverpool. A pauper in the Liverpool Workhouse, had lately become lunatic, and during one of her fits of violence Dr Nevins, the Medical Officer, ordered her to be soothed with chloroform. This was done by Mr Lupton, a student of Dr Nevins. On the next occasion, when a maniacal fit supervened, the Governor of the House applied the chloroform. The woman was held down in bed, and the Governor administered chloroform on lint: in the course of eight or ten minutes a change took place, and the "master tailor," who was one of the spectators of the proceeding, said, "She is gone!" She, indeed, was dead. Here is another proof, if another were wanting, to demonstrate the extreme impropriety of lay persons having recourse to so powerful and dangerous a means of medication. Chloroform is safe in judicious hands; but, if administered by one who is ignorant of its mode of action, and of all the delicate precautions that are necessary to be observed to insure safety, it may become, as in this and many previous instances, the cause of instant death. It is possible that in some of these cases it is not, in reality, the chloroform that causes death, but the absence of it; the patient dying of simple suffocation. Between the fear of giving too much and the desire to induce insensibility, enough is not given, and the insensibility, at length forced, is produced by asphyxia. The Jury acquitted the Governor, and suggested that a Resident Medical Officer should be appointed to the Workhouse—a recommendation that, we hope, will be carried into effect.

THE NEW LICENTIATES OF THE COLLEGE OF PHYSICIANS.

It is now fully understood that the scheme of the College of Physicians to create a new body of Licentiates is illegal; the Attorney-General, Mr Roundell Palmer, Mr Bovill, Mr Wilcox, and Mr Cleasby—a phalanx of high legal authorities—having concurred in opinion on this point. Nothing can, therefore, be done without an Act of Parliament. We are glad of this; because it will give the Profession an opportunity of petitioning against the Bill, should it contain any clauses which would tend to create an inferior grade, or deprive existing Licentiates of their rights.

A RELATIVE OF JENNER.

Mrs Elizabeth Jenner, the wife of Jenner's grand-nephew, has been twice defeated in her candidature for admission to the Royal Medical Benevolent College. She now makes a third appeal to the subscribers. Will not the subscribers for once forego the pleasure of a contest, and combine their votes to provide an asylum for one of the family of Jenner in her distress? The Profession ought not to allow this lady to sink unaided under her misfortune. It would be an unspeakable disgrace to us if we should suffer a lady bearing that illustrious name to ask for shelter under the roof of our own Charity, and bar our doors against her appeal. The excitement arising out of a contested election to a Charity affords, no doubt, an agreeable kind of amusement; but if indulged in to the prejudice of those who have peculiar claims to the help of the Institution, it becomes an unpardonable abuse.

THE MEDICAL DIRECTORY.

The Annual Circular of the Medical Directory is about to be issued, when an opportunity will be afforded to every member of the Profession to show their estimate of the value of the work by complying with the Publisher's request and ordering a copy. No expense is spared by the enterprising Publisher to merit general support; for we hear that for the future the three Directories for the three divisions of the Kingdon will be included in one handsome volume extending to more than one thousand pages, and all for the very moderate sum of 8s 6d. Considering the large expenses attending the compilation of such a work, we should think that there is not such another instance of cheapness in the whole range of literary undertakings. We quite concur in the recommendation of our contemporary in the current number of the 'Medical Times,' who says: "Every well-wisher to the Profession must see the importance of supporting so valuable a work of reference as the 'Medical Directory.'"

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 42.)

Visitations of adverse fortune read wholesome lessons, and if sustained with fortitude, temper the feelings, and expand the affections. John Hunter finding the regrets and sorrows of his sister not capable of alleviation, barren sympathy being all he had to bestow, was assailed by serious misgivings at the unprofitable life he had hitherto spent, the consequences of which, arising from a similar source, he found reflected in the difficulties and distress of his beloved sister. The blandishments of country sports, no more than the fascinations of music, and society, would compensate or recall lost opportunity and misspent time. The results of idleness, dissipation, and indulgence he had witnessed afforded bitter fruit, made these attractions fade, and better aspirations took place. Becoming restless at his position, and anxious for occupation, he addressed, with much hesitation, a letter to his brother William in London, whose success was now established, requesting to be permitted to pay him a visit, and offering to assist in the dissecting-room. If this proposal had not been accepted, he intended to go into the army; being of an enterprising and adventurous temperament. By absence from home he had become weaned of boyish attachments, and Mrs Hunter had also become reconciled to the absence of her son, being troubled for his future welfare, which her daughter's misfortunes more strongly prompted. Dr Hunter returned an affectionate reply to his request, with an invitation to come up immediately to London to assist him in anatomical pursuits. This was cheerfully accepted, and in company with a Mr Hamilton, who was visiting London on business, they travelled together on horseback, and in September, 1748, reached London. John Hunter was eighteen years old when he entered William Hunter's dissecting-room. This occurred about a fortnight before the winter session of lectures commenced. William, to test the disposition of John for anatomical pursuits, and to form some opinion, as well as to estimate his abilities, after preliminary instructions, gave him an arm to dissect the muscles; the performance of which, it is recorded, greatly exceeded the anticipation of William Hunter. This, in some measure, decided his fate. Upon his accomplishing a much more difficult dissection to the entire satisfaction of William—namely, a preparation of the arm, showing all the muscles, with also the arteries injected for preservation—William determined to engage John in regular employment in the dissecting-room, and declared his conviction that he would soon become a good anatomist, and should not want for employment.

All the dissections of that day in London were performed in William Hunter's School of Anatomy; John therefore did not want opportunity and practice. He quickly excelled in the tact and neatness of manipulation required to attain excellence in dissection, and making preparations, which, as in other arts, to be successful should be attained early in life. His efforts were much assisted by the instruction he received from his brother's dissecting assistant, Mr Symonds. Notwithstanding latent manifestations of that jealousy which ultimately broke into open hostility and undignified contention, Dr Hunter at this time showed great interest for the welfare of his brother. He interceded with Mr Cheselden to admit John Hunter to the sick wards of Chelsea Hospital, of which that eminent man was surgeon. Under this tutelage, he very early in life, being only nineteen years of age, received the first instalment of the large experience which afterwards distinguished him—derived amongst veterans of the army, to the service of which he afterwards devoted his matured experience on foreign service, and on the field of battle. The oft-told

tale of adventure, of danger, and of suffering, would leave impressions in the vicissitudes of his future career, not unprofitable upon a mind predisposed to enterprize. He continued his attendance at Chelsea Hospital during the next summer. It was at this period John Hunter first manifested an interest in physiological inquiry, and those speculations in which he afterwards indulged.

From the observations he made in the wards of Chelsea Hospital, he expressed doubts of the doctrine, that in the process of ulceration, solid parts are held in solution by pus or matter. His advance in anatomical dexterity was steady and rapid: in the next session, he relieved Dr William from demonstrations in the dissecting-room, to devote his labours exclusively to the duties of giving lectures in the lecture-theatre.

In 1751, he became pupil of the celebrated Percival Pott, one of the senior surgeons of St Bartholomew's Hospital,—attended his lectures, and also the clever operations performed by that skilful man. He thus enjoyed the singular privilege of receiving early instruction from the two greatest reformers of the art and science of surgery. These two eminent surgeons may be considered the Calvin and Luther of surgical reform: one boldly assailed the monks and barbers who had usurped the practice of the art, and got possession of hospitals and lazar-houses endowed by royal munificence. The other had rather more of the amiable and learned Melancthon in his nature, and by gentle and persuasive means established a humane and skilful practice. Improved pathology and surgery thus founded, could not have received worthier culture, or possessed a disciple more zealous and talented than John Hunter to hand down its traditions, enlarge its field of inquiry and labour, and establish the claims of medicine and surgery to the dignity of science. Although in after-life he assailed some of Mr Pott's pathological doctrines and opinions, he always expressed the greatest esteem and respect for him, notwithstanding the unfortunate quarrel, in which he took no part, between Dr William Hunter and Mr Pott. This dispute necessarily produced between them some coolness and, perhaps, jealousy, but it was manifested more by Pott than John Hunter, who was now beginning to take a high position as a surgeon. No two men could be more opposed in their manners, and modes of thought than John Hunter and Percival Pott. The last, a man of refined and cultivated tastes, and an excellent scholar, considered surgery essentially a practical art, which he vindicated and illustrated—being a most elegant and fearless operator—and in his lectures displayed learning, eloquence, and research, appealing to the authority of writers of antiquity in support of the opinions he promulgated. It is not improbable that the confusion and blunders of Pott in regard to congenital hernia—or, as he rather affectedly termed it, *hernia congenialis*—led to those further discoveries which, by the inquiries and experiments of Haller, the two Hunters, and Monroe Secundus, ultimately settled this vexed question. But John Hunter had no better claim to the discovery of the *hernia congenitalis* than had Percival Pott; that merit belonged to Baron von Haller, of Gottingen and Berne. Hunter's discovery—and perhaps the most important, most appreciated, and least disputed of his life—was the transition and progress of the testis from the abdomen into the scrotum. John Hunter held surgery to be a subject for speculative inquiry and physiological research, and had no veneration for authority; he was a genuine reformer, maintained the right of private judgment and freedom of thought with independence and boldness. But physiology had made no progress as a science at this time, to give sufficient faith in its conclusions to satisfy the convictions of Percival Pott.

The turning point of John Hunter's career was now in the eddy. He hesitated which department of practice to adopt, and the circumstance of entering as a gentleman commoner in St Mary's Hall, Oxford, in 1752, would indicate the intention of ultimately graduating, with the object of becoming, at a future time, a Fellow of the College of Physicians, for at this time William had not decided to relinquish the practice of surgery. But not matriculating—in short, he did not reside, since his London employments were not interrupted for a moment by his absence—this plan was relinquished, and he entered as a surgeon's pupil at St George's Hospital the following year. The inclination manifested by John Hunter was decidedly for the practice of surgery, and he thus early entertained the ambition of becoming surgeon to a hospital. The prospect of succeeding Cheselden at Chelsea was very remote. So far as regards surgical practice, Chelsea Hospital was unequal to the ambition he entertained, since, in the instance of Cheselden, it was bestowed more as a royal favour to smooth his retirement from the labours of the Profession. The regulations of St Bartholomew's requiring of the candidate for the office of surgeon, that he should serve an apprenticeship with one of the surgeons of the hospital, precluded his prospects in that direction. Dr William Hunter possessed some interest and influence with the Medical Officers of St George's Hospital, through which John hoped for more success, and to be able to gratify, in due course, the ambition of becoming surgeon to that hospital. As a stepping-stone, he obtained the situation of House Surgeon at St George's Hospital, about 1756. The temporary position of house-surgeon being a most desirable one in which to obtain practical knowledge of responsible surgical duties, requiring constant attendance in case of accidents brought to or occurring in the vicinity of the hospital. The different early training of the two brothers became now more manifest. From the age of fifteen, William had been accustomed to the discipline of College life at the University of Glasgow, to qualify him as a candidate for the Church. He thus became a good scholar, and able to sustain any position in which fair classical acquirements might be necessary. This, combined with a taste for public speaking, made him unequalled as a lecturer, and gave a cultivation to his style of address always popular and pleasing. John Hunter, on the contrary, never having enjoyed similar opportunities of instruction, and the few which had offered having been neglected, he could not retrieve his disadvantages by any later efforts, since the active and laborious pursuits of the dissecting-room, of practice, and ultimately of lecturing, afforded little time for mental culture. He felt this disadvantage keenly, and it gave a tone to the future pursuits of John Hunter, whose vigorous mind nevertheless acquired by these impediments a more forcible rebound.

(To be continued.)

CLINICAL REPORTS.

Extra-Uterine Gestation (Interstitial?)—Operation by External Incision, and Removal of a nearly full-grown Child—Recovery.—Dr Ramsbotham and Mr John Adams.

Cases like the following are not often met with in hospitals; but, as they may arise at any moment in the practice of any surgeon, it is well to be able to decide as to their nature. The case has occurred in the practice of Dr Ramsbotham, at the London Hospital, and is now thought to have been one of "interstitial" extra-uterine gestation. Dr Ramsbotham has had sixteen somewhat similar cases.

Extra-uterine gestation differs from superfœtation in the now well-recognised fact, that in the latter (as in anomalous cases of twins in the West Indies, where one child is white, one black), one gestation having commenced, a second supervenes or may supervene upon it during the continuance of the first: whereas in the former, or extra-uterine gestation, the ovum may be impregnated, and become abnormally attached and developed, as in the case about to be related, at some or any point between the upper part of the uterus and the Graäfian follicle; or it may fall into the abdominal cavity itself, giving rise to the varieties of this accident known as ovarian, tubal, ventral, and interstitial. In the first, the ovum is impregnated in and attached to the Graäfian follicle, or external surface of the ovary itself. A marked case of this kind has been given by Dr Granville. A lady, aged thirty-nine, was the mother of seven children; the tumour, four times the size of a hen's egg, contained a fœtus of about four months' growth, which, as such tumours are generally found to do, burst in several places, the poor lady dying of the hæmorrhage and general "shock" to her system.

The "tubal," or second variety of extra-uterine gestation, is, however, the most frequent of these abnormalities. We give two cases by Dr R. Lee; they also show the usual termination of these very serious accidents.

"A patient died suddenly in 1829 from internal hæmorrhage," says Dr Lee, "produced by rupture of the right Fallopian tube, which contained an ovum. On opening the tube a deciduous membrane was found everywhere surrounding the chorion, adhering to the tube, as the decidua usually does to the lining membrane of the uterus. The chorion, placenta, amnion, and embryo were distinctly seen.

"A second patient, Mrs K——, after suffering under symptoms of inflammation and retroversion of the uterus, was seized with great faintness, and soon expired. A large quantity of fluid blood was found in the abdominal cavity, and the right Fallopian tube was lacerated, which contained an ovum with deciduous membrane also."

One of the causes of extra-uterine gestation is believed to be emotional excitement or fright on the part of the woman at the time of coitus or impregnation. The symptoms in such cases as these are at first not very well marked or distinctive. The uterus is felt to be developed; it is high up, and at one side; menstruation ceases; there is an absence of nausea and vomiting; the patient feels very uneasy; fœtal movements are indistinct; there is a sense of weight and uneasiness deeply seated in the pelvis, extending to the kidney, no doubt from irritation of some common nervous supply. In tubal gestation, from the confined space of the tube, the ovum is continued in it rarely beyond the third month, when the cyst or tube is ruptured, and the embryo escapes. In some rare cases it goes on to the full time; but when it bursts, the poor woman, without any idea of what has happened, is seized with agonising pain, followed by ghastly pallor, fainting, hurried breathing, and collapse. On dissection, the ovum is found in the abdomen; a rent exists in the tube, and a large quantity of blood in the peritoneal cavity. In the "interstitial" variety, as compared to the "tubal," the infant in the former case usually goes the full time; but, as there is a something absent in the womb to set up ordinary labour at that time, as in the following case, the child dies. Matters then go on more or less quietly for some time, not without injury to the health of the mother, but without danger to her life. The crisis, however, must come sooner or later, when the cyst gives way, and symptoms of collapse set in, followed by those of inflammation. This crisis may be hastened by various circumstances, such as violent action of the abdominal muscles, sudden shocks, coughing, vomiting, &c. It was with the object in view of anticipating such evil results in the case appended, that the surgeons of the London Hospital decided (now that the operation is so easily done under chloroform) to operate; for Dr Campbell, it may be remembered, gives seventy-five cases of this disease, in seventy of which the fœtus—shall we say?—after the manner of Ariel and Sycorax, continued interstitially confined for several years in the walls of the womb itself,

"within which rift
Imprisoned it did painfully remain."

Dr Dyce, indeed, of Aberdeen, gives a case in which the fœtus was thus retained for a period of eight years. The patient was twice pregnant afterwards, and delivered of living children, but sunk ultimately from the hectic brought on by the extra-uterine fœtus in process of decay.

The case which we have deemed it right to preface by the preceding remarks is only the second known of its kind in our hospital annals, operated on as this was: they may arise, however, at any moment, and the question of surgical operation become a very serious one.

M. A. J——, married eight years, a young-looking woman under thirty years of age, was admitted in May of the present year, under the care of Dr Ramsbotham, at the London Hospital, with the following curious history:—Though married eight years, she has never been pregnant till her present trouble. She ceased menstruating last February twelve months; this was succeeded by cramp-like pains in the right side of the abdomen; she was sick, but did not vomit; had no ensuing sickness; the pain reached from the pelvis up to the region of the liver. In June '59 she first felt a movement as of a child; her breasts began to enlarge also, and the veins of the left leg became varicose; in short, she

experienced the first familiar indications of being in the "family way." She continued in good health in this condition up to the end of October—got stouter and stouter. About this time, however, she fancies she had a severe fall, followed by cramp and soreness in her side, with pain running down to her knee. On the last day of this month she received intelligence of the death of a sister, which caused considerable "shock," though there was no new abdominal sensation, only that from this time forward she ceased to feel the movements of the child, and, as she now thinks, became sensibly smaller, though the period of gestation should terminate in November according to her own calculations—that is, some days later.

About a week after the movement ceased, a discharge of blood commenced from the vagina, blackish and occasionally pinkish, sometimes with pieces of coagulum like flesh, not offensive, but without pain, though in gushes. She did not feel herself so well as usual; she felt sleepy and weary, with stiffness in the limbs. This continued till December.

January, 1860.—Nothing unusual occurred this month, but that she was very anxious about herself.

February and March.—What she considered "menstruation" commenced in these months, and was regular up to the time of her admission to hospital. There is milk in the breasts, but this disappeared in March. Her general health still suffers: indeed, since October she has been getting smaller and thinner, and very uneasy about her state.

April and May.—Still very apprehensive about her condition, and wishes for some midwifery interference or operation, to rid her of what proves, on examination by Dr Ramsbotham, a hard tumour, of the size of a man's head, easily detected, chiefly on the right side of the belly! not painful or sore to the touch; the os uteri being felt high up, but natural. She had improved somewhat in hospital; her appetite was good, she slept well, and had a good pulse. A consultation of the surgeons of the London Hospital was held, and as the woman had evidently gone nearly six months "over her time," and as she was particularly wishful herself for some operation, it was deemed advisable, though very serious surgery, to operate, the case being supposed to be one of extra-uterine gestation, probably of the "tubal" or interstitial kind or variety.

The operation (May 31st) was performed with Mr Adams's usual steadiness and anatomical accuracy. After chloroform had been administered, an incision about five inches in length, commencing on a level with the umbilicus, and about two inches to its right side, was made, and carried to about an inch of the pubes, also on that side, going, of course, through integuments of abdomen, and rectus muscle, and peritoneum, much as in the minor incision for ovariotomy (an operation, perhaps, of a more formidable kind, but which has now been done 395 times, with 212 cures). The tumour at once came into view, and was found adherent to the abdominal wall at its lower part. The tumour or cyst was now punctured, and about a pint of greenish yellow fluid, with some flakes of "vernix caseosa" and some loose hairs, came away. The cyst (or membranes) was then opened, and a loop of funis escaped. Mr Adams next introduced his hand, and drew out a fœtal arm. The child (a female) was found very nearly arrived at maturity, well nourished, but, of course, dead. The placenta, of a very enigmatical kind, half macerated, was allowed to remain, and the funis tied; some omentum having protruded, part of it was cut off, its vessels ligatured, and the remainder returned; the cyst was carefully sponged out as in ovariotomy, the edges of the external wound brought together by sutures, and, strapping the ends of the ligatures and funis, left hanging out of the wound; the abdomen was supported with cotton wool and lint, with a woven bandage over all; thirty drops of tincture of opium given directly, and ordered to be repeated every hour till sleep was obtained; and the poor woman was carefully removed to bed, where she soon recovered from the effects of the chloroform, and was delighted to find the operation was all over. She complained, however, of feeling some pain for three hours after the operation; but then she fell asleep for a half-hour, and awoke refreshed. Later in the evening, she vomited; complained of thirst, but suffered less pain; she had ice to suck, and the laudanum was repeated every four hours; pulse was reported good, and she passed (all things considered) an excellent night.

June 1st.—Had some beef-tea for breakfast; felt refreshed, pain less. Took iced brandy and water, as also her beef-tea, freely through the day. Later in the day, felt a pain in the wound; this was relieved by the laudanum.

2nd.—Slept well; no pain; tongue clean and moist; slight headache, probably from the opium.

3rd.—Passed a good night: no pain or tenderness; felt hungry, and had some fish. Bandage and dressings removed: wound looking healthy, with slight discharges; bread poultice applied. Towards evening, slight spasm of the chest.

4th.—Slept well; wound looking well, discharge increasing.

5th.—Less pain; pulse 120; tongue furred; wound healthy, but discharging freely a grumous-looking matter, which Mr Adams believes to be broken-up placenta, the remains of the cord, too, having been observed in the poultices. She had six ounces of good sherry-wine, beef-tea, and fish.

6th.—Passed a good night: tongue, however, is dry; and as the bowels have not been relieved since the operation, Mr Adams ordered two drachms of castor-oil, which acted freely.

7th.—Had some jelly and a chop, and eight ounces of wine. The entire wound has now healed by "first intention," with exception of lower end, whence the ligatures hang, and discharge freely escapes.

12th.—Some of the ligatures removed, followed by half an ounce of offensive grumous fluid.

19th.—Remainder of the ligatures removed. She is now able to sit up. Takes four ounces of wine, chop, and pint of porter. Discharge is decreasing.

July 14th.—Now six weeks since operation. She is walking about the ward, convalescent. Some slight discharge still continues, but otherwise she seems a miracle of good surgery, and many strangers (medical) have come to see her. The case, in point of fact, has proved to be one of the most remarkable and suggestive in the entire field of surgery.

We need only say, in conclusion, of this form of the disease, first described by Breschet, that the ovum lodges near the point at which the Fallopian tube enters the uterus, and forms, as it were, a nidus in the walls of the uterus itself, where it becomes "surrounded by a layer of the muscular coat similar to the layer which surrounds the majority of fibrous tumours; it is developed in a kind of sub-cavity between the uterine layers at one of the Fallopian angles." Indeed, one or two cases are given in which the ovum was found in this position; the placenta had occupied the uterus, and the rest of the ovum had been contained in a cyst formed by the dilated Fallopian tube.

EXTRA-UTERINE GESTATION, ATTENDED BY USUAL SIGNS AND INDICATIONS OF PREGNANCY — BONES OF FŒTUS PASSED HER RECTUM, TWELVE YEARS AFTERWARDS. — MR SYDNEY JONES.

As a pendant to the former case, we may here mention another instance, where the component parts of a fœtus of a supposed extra-uterine gestation were passed by the rectum. The bones have been shown recently at St Thomas's Hospital, by Mr Sydney Jones. The case is as follows:

A woman, now aged fifty-six, says that twelve years ago she had many, if not all, the usual symptoms of pregnancy—enlargement of the abdomen, development of areolæ round the nipples, &c. In due time symptoms of labour supervened, but, to her mortification and astonishment, passed off again. She then consulted a medical man, and the uterine enlargement was examined, but found more at one side (the right side) than the other. For the next twelve years she had no further annoyance, though the tumour remained; but at the end of that time, during the last two years, the cyst or abscess has given way or got less, and she has passed, *per rectum*, a series of bones which prove to be those of a fœtus. The woman is now in remarkable good health. The "vis medicatrix" in this instance has proved herself quite equal to the task of perfecting a cure; but, on the other hand, it was just as likely that the case might have ended fatally, like those just referred to in the practice of Dr Granville and Dr Robert Lee.

BRITISH ASSOCIATION AT OXFORD.

ABSTRACTS OF PAPERS.

Dr EDWARD SMITH read a paper on "The Action of Tea and Alcohols contrasted," in which he demonstrated, in reference to tea, that it excites or increases vital transformations, increasing the frequency, depth and chemical changes of respiration, as well as the action of the skin, as shown by increase of perspiration. Fat and acids lessen this action on the skin, but alkalis increase it. Tea is chiefly of use after food, but is not applicable as a substitute for food; and, to descend to the nursery tales of every-day life, Dr Smith thinks tea is very unfitted for breakfast, as well as for persons of spare and active habits; nor is it fitted for prisoners, the ill-fed and destitute, or young. It is most fitted for the old, the corpulent, for the sedentary, for soldiers or for hot climates, and it is especially fitted to aid in the transformation of starch and fat foods. Coffee, on the other hand, according to his researches, lessens the action of the skin, lessens the necessity for transformation of food by acting upon the kidneys and bowels. Coffee lessens the consumption of food, tea increases it; the former conserves animal heat, the latter disperses it. Of the alcohols, beers, and wines, true to an old legend, rum seems to be the most complete and perfect stimulus; but Dr Smith believes all such compounds are poisons, and not foods. Beers he thought to be valuable according to the amount of gluten, sugar, acids, and salts which they contain; and old-fashioned ales are better for hospital patients than the thin bitter trash (Bass—"base," and "all slop"—Alsop, as some one remarked) now so fashionable. Tea and good beer have an analogous action. The Author reprobated the introduction of fashionable ales into India, believing, from their power to lessen the action of the skin, their usefulness would be very doubtful in that country; but this point seemed open to discussion, as well as the real action, in disease, of wine, brandy, &c., as held by the late Dr Todd. The "Section" seemed, however, comfortably confident that the old-fashioned ales, with their gluten, sugar, acids, salts, and peradventure variable but intelligible percentages of half-formed alcohol (one or two of the colleges at Oxford being celebrated for their inimitable malt and hops), were all that could be desired, and deserved Dr Smith's eulogium.

Dr CHARLES KIDD, in a paper on the "Nature of Death from Chloroform," introduced to the "Section" the much-vexed question of the class of cases where chloroform is comparatively safe, and that class where caution is required in the administration. Dr Kidd furnished in the paper a careful analysis of all the recorded deaths from chloroform given for operations, which amount to about 100, as also an analysis of twenty-five additional deaths from the administration of ether and amylene. Dr Kidd is inclined to doubt if the deaths from chloroform have been, as held by Dr Snow, from cardiac syncope, from overdose of chloroform, sinking of the heart, &c. The fact of tens or hundreds of thousands of patients taking chloroform with perfect safety, even in the largest possible doses of six, or eight, or ten ounces of chloroform at a time, many remaining an hour or two hours under chloroform in deep sleep, the pulse little if at all affected, the heart undisturbed, &c., he cannot reconcile with the other fact, that in all the fatal cases the dose of chloroform has been very small (a drachm or half-drachm), the death has occurred before deep anæsthesia had commenced; in many deaths, also, the heart had gone on beating, but the breathing had ceased! Judging from experiments on animals, and what he has himself seen in the post-mortem examination of patients in hospitals, who have died from chloroform, as well as judging by the view of Brown-Séquard on chloroform, Dr Kidd thinks the larger number of deaths arise from an excitant reflex action of the chloroform in the early stage, and not a deep, direct, and later depressing action or exhaustion; and that the base of the *brain*, not the heart, (through a reflex irritability from the pulmonary organs, especially from the pneumogastric nerve, as well explained by Einbrodt and Weber,) is the part really at fault. We have accordingly to dread hysteric and nervous complications in the brain, as well as trivial operations where chloroform or bad chloroform is given in a trivial manner in small doses, infinitely more

than we have to fear diseased valves of the heart, or the fullest doses of chloroform continued with due care even for an entire hour. This reflex or excitant action of the pneumogastrics may even stop the heart, if not hurried over by cautiously increasing the dose of chloroform, as any other excitant of the pneumogastric is found to do; or this reflex action may, by vaso-motor disturbance and dilatation of vessels in the brain, lead to increase of blood and sudden "fit."

This paper, which it is difficult to make clear to the general reader without the diagrams and statistical tables, gave rise to a long discussion, in which Sir B. Brodie, Mr Busk, Dr Sharpey, Dr Priestley (Professor Simpson's chief assistant), and several others took much interest.

Mr. Busk thought the statistics of the 125 deaths very remarkable; but he still believes, what is not antagonistic to Dr Kidd's theory, but supports it, that some deaths arise from mere surgical "shock," and are then put down to chloroform.(a)

Dr Priestley, in the only case of death he saw from chloroform, the heart continued to beat, though the breathing had stopped. This corroborates Dr Kidd's views.

Mr Durham, of Guy's Hospital, brought before the Association some experiments on the "Physiology of Sleep," already referred to by us in Mr Hilton's recent Lectures at the Royal College of Surgeons. This question, though apparently so simple, is one of the most unsettled in the entire field of physiology and practice of medicine. Sleep was defined by the Author to be a state of cerebral repose which is essential to the nutritive repair of the brain substance; a state in which consciousness, sensation, and volition are temporarily suspended, but so suspended as to be easily restored by the action of stimuli external or internal. Mr Durham, by removing portions of bone by the trephine from the skull of animals, and substituting watch-glasses as "windows," was enabled to investigate the state of the brain during sleep: he found that in this state the brain is comparatively bloodless; the veins are NOT distended, as usually stated by physiologists, and the capillaries contain very little "corpuscnlated" blood; during waking the circulation is much more active, and at that time arteries, veins, capillaries, all highly injected with rapidly-moving blood. The relation of the intracranial circulation with that of other parts, and the theory of the cerebro-spinal fluid and veins, as in Mr. Hilton's lectures, were next dwelt upon. Coma and lethargy, and anæsthesia from chloroform, were proved to be very distinguishable from healthy sleep; the nature of dreams was also explained, and some very admirable suggestions were made as to the best method of inducing sleep under various conditions of wakefulness in disease. Mr Durham's communication excited considerable interest; the experiments, taken in conjunction with those of Dr Burrows and others, were very valuable and suggestive.

M. Ollier exhibited some specimens illustrating the production of bone from periosteum. We have so frequently referred to these experiments of M. Ollier in the Medical Circular, especially in connection with the phosphorus disease of the inferior maxillary bone, that we do not see much use in again going over exactly the same ground.

Dr Radcliffe's paper on "Muscular Action" is in the same category of communications as that by M. Ollier.

Dr Richardson brought before the Section his views on "The Process of Oxygenation in Animal Bodies." The inhalation of oxygen has also been very fully discussed in some original papers in this journal; and partly to reconcile some of these conflicting statements and discussions, seems to have been the chief object held in view by the Author. The influence of pure oxygen as an excitant differs according to the kind of animal on which it is tried, being (as one would *à priori* expect) most marked in animals of quick respiration and high temperature, and least marked or *nil* in animals of feeble respiration and lower temperature. Oxygen when breathed over and over again, though freed from carbonic acid, loses its power of supporting life; and oxygen, while it is essential to muscular irritability and muscular power, exerts its influence over muscle, not as a direct excitant, but by supplying to the muscle an agent or force by which the muscle is fitted for contraction on the application of an exciting cause. Dr Richardson thinks, too, that there is a withdrawal of some principle extant in primitive oxygen in the finer experiments; but, like voltaic narcotism and ammonia as the sole cause of coagulation of the blood, this compound nature of oxygen was doubted.

(a) Dr Barnes gives a recent midwifery case, death seventeen hours after chloroform; the patient in the interval quite conscious and apparently well.

INTERNATIONAL STATISTICAL CONGRESS.

THE SANITARY SECTION.

The papers announced in the programme at the opening of the Fourth Section were—on General Sanitary Statistics, by Dr Farr; on a Uniform Scheme of Sanitary Statistics, by Dr Sutherland; and on the Statistics of Hospitals, by Miss Nightingale. Additional topics were announced by Dr Jarvis, on a Uniform System of Reports in Lunatic Asylums; by Dr Milroy, on Simultaneous and International Registration of Epidemics; by Mrs M. A. Baines, on the Statistics of Wet-nursing; by Sir David Brewster, on Colouring Blindness.

Taking these subjects in the order in which they were entertained in the Section, we notice first the paper of Miss Florence Nightingale, on the Method of Reporting Hospital Statistics, read on Tuesday, 17th July, to which we briefly referred last week. In this paper it was proposed that each hospital should tabulate its annual work according to "diseases," "ages," "sexes," and that under each disease should be shown—1, the numbers remaining at the beginning of each year; 2, the numbers admitted during the year; 3, the numbers cured; 4, the numbers discharged incurable, unrelieved, or at their own request; 5, the deaths; 6, the duration of cases; 7, the numbers remaining at the end of each year. The forms prepared for collecting this information, and submitting it to the Congress, had been already tried in several hospitals, and the results were considered sufficient to show how large a field for statistical analysis and inquiry would be opened by their general adoption. They were considered sufficient to ascertain the relative mortality in different hospitals, as well as of different diseases and injuries at the same time and at different ages, the relative frequency of various diseases and injuries amongst the classes which enter hospitals in different countries, and in different districts of the same country. They would enable us to ascertain how much of each year of life is wasted by illness; what diseases and ages press most heavily on the resources of particular hospitals. For example, it was found that a very large portion of the limited finances of one hospital was swallowed up by one preventible disease—rheumatism, to the exclusion of many important cases or other diseases from the benefit of the hospital treatment. It had been shown that most of the cases admitted to the hospitals, where the forms have been tried, belong to the productive ages of life, and not to the ages at the two extremes of existence. The paper stated, that the relation of the duration of cases to the general utility of an hospital had never yet been shown, although it must be obvious that if, by any sanitary means or improved treatment, the duration of cases could be reduced to one-half, the utility of the hospital would be doubled, so far as its funds are concerned. The proposed forms would enable the mortality in hospitals, and also the mortality from particular diseases, injuries, and operations, to be ascertained with accuracy; and these facts, together with the duration of cases, would enable the value of particular methods of treatment and of special operations to be brought to statistical proof. The sanitary state of the hospital itself could likewise be ascertained. The statistics of rare diseases and operations are still very imperfect; but by abstracting the results of such diseases and operations from the tables after a long term of years, trustworthy data could be obtained to guide future experience. The proposed hospital forms were all alike, differing only in the headings, which it was proposed shall be those given above. The nomenclature is the one agreed to at the Paris meeting of the Congress, and the classification is essentially the same as that used by the Registrar-Generals of the United Kingdom, with a few modifications to include rare diseases, tumours, &c.

Dr Varrentrapp, though acknowledging the necessity of making a distinction between diseases and diseased persons, did not approve of making two statistics, which would be an unnecessary and useless labour. He said, "out of 100 cases of typhus fever, there may be 14 who will have a different disease; you must see what the second disease is, or you will not have any particular result." He thought it important to give the day of entrance into the hospital. He agreed with Dr Neumann as to the importance of giving the result of typhus; that on such a day came the crisis, on such a day you bled for the last time, and that on a certain day the patient left the hospital cured. He thought that transference from one part of the hospital to another should be avoided, unless one disease had been cured and another had commenced. Speaking of his own hospital, he said, "If a patient goes in with a broken leg, I dismiss him after the lapse of a certain time with regard to that, and enter him the same time in another part of the hospital for the itch, or whatever his other complaint may be." He thought the diagnosis was often published prematurely, observing that we may think, in the beginning, that we have a case of typhus fever, which, after a few days, turns out to be a different disease. It was not always the case that in those months in which the greatest number of cases occurred, there were the greatest number of deaths; but there were months in which the disease occurred less frequently, and the deaths were more numerous. He would, therefore, wish the ages and the months to be marked.

After much discussion on various collateral subjects, the paper of Miss Nightingale was adopted by the Section; and it was resolved that its recommendations be made known to the different Governments.

The proposals for a uniform scheme of sanitary statistics were embodied by Dr Sutherland in fifteen propositions, referring to the influence of age, sex, occupation, locality, climate, and general sanitary condition, on mortality; the propositions to be embodied in tabular forms. These forms would include the conditions under which the population of any particular town or district may be placed as to local climate, soil, drainage, paving, area occupied by the population, with the facilities for external ventilation afforded by the structure or position of the town; the length of the streets, with their breadth in relation to the height of the houses, and the internal condition of the latter as regards repair, cleanliness, light, ventilation, and cubic space for the inmates; also the water supply, its nature, quality, and amount; the statistics of food and drink, and their consumption; the classification of trades and occupations influencing health; and the statistics of interments.

These proposals were adopted, subject to certain additions as to the sanitary statistics of hospitals, schools, drained and undrained houses, common lodging-houses, and sleeping-rooms.

On the subject of dwellings provided for the labouring classes, and adapted to their requirements, by societies, &c., Dr Greenhill proposed a series of inquiries relating to the influence they exert on sanitary interests, and also their cost and value as investments. These inquiries were to embrace the occupation of the inmates, including the mothers, and the number of children attending school. Dr Ballard suggested that the inquiries should refer also to "class," and the portion of Irish occupants. These recommendations were adopted.

On the fourteenth proposition, for a classification of trades, &c., it was doubted whether the proposition referred to the influence which trades exert over the sanitary condition of a neighbourhood, or on the persons engaged in them. Dr Sutherland was not prepared to propose a scheme on the latter point. Dr Ballard suggested a method which he handed in, and which was referred to a Committee, who adopted it on the following day with a few modifications, leaving it as follows:

That any scheme for the classification of occupations, trades, businesses, and manufactures, having regard to their influence upon the persons engaged in them, should be based upon their character as respects the following points:

1. Whether they involve severe or moderate bodily exertion, or the reverse.
2. Whether they are carried on in the open air, or in shops, warehouses, offices, or other confined places.
3. Whether they involve exposure to vapours or miasmata of any kind, or any kind of dust (including all those usually deemed unhealthy from these causes).
4. Whether they involve the maintenance of a constrained posture, or any local pressure.
5. Whether they involve an unusual amount of exposure to the weather, to heat or cold, or sudden alternations of heat and cold.

That in respect of trades, &c., the distinctions of masters and employed should be recognised.

That the following should be the primary divisions of the classification :

I. Persons of rank or property, including manufacturing and trading capitalists.

II. Persons in learned professions, and persons practising superior arts.

III. Persons *actually* engaged in the defence of the country, specifying rank and particulars of occupation.

IV. Persons engaged in the mercantile marine, or otherwise, on the sea, rivers, or canals.

V. Individuals *personally* engaged in occupations, trades, businesses, and manufactures, or other employments not embraced in former sections,—

1. Involving severe bodily exertion ;
2. Involving moderate bodily exertion ;
3. Not involving bodily exercise.

Dr Farr's paper on General Sanitary Statistics embraced the following topics :

1. The sanitary condition of each nation, and of each circumscription, such as district in England—*arrondissement* in France, should be distinctly exhibited. The rate of mortality per 1000, over a series of years, should be determined.

2. The mortality, the mean lifetime *(vie moyenne)*, and the fatal diseases of each population, should be determined for the whole people, and for (*a*) the healthiest districts, (*b*) the unhealthiest districts, and (*c*) all the considerable cities. For this purpose life tables should be constructed.

3. At the census the numbers suffering from the principal infirmities, and from the diseases which disable people from following their ordinary occupations, should be ascertained. The numbers sick in hospitals, their mortality, and the duration of their illnesses, should be investigated ; and wherever it is practicable, the investigation should be extended to other classes of the population, and notably to the members of all Friendly Societies.

4. The stature, the weight, the strength, the working power, and the intelligence of the people, are indications of health, which should be explored in groups of the population at each age, wherever that is practicable.

5. Amongst the causes which are found to have the greatest effect on the health of the people, are the air they breathe and its various impurities, their contiguity to each other, their food and drink, the action of their minds and muscular effort, or exercise and labour. In investigating the causes, the effect of varieties of habitation, density, proximity, elevation, latrines, income of the population, should be therefore especially investigated. . ..

6. The occupations have a marked influence on the health of the people, and it is found that by easily-arranged modifications the trades most injurious to health can be made innoxious. The Section, therefore, recommends a special inquiry in every State into the effect of the principal occupations of its people on health. To secure uniformity, the forms of which examples are given, as applied to the miners of England, are recommended for adoption, with such others as circumstances may suggest.

7. The Section strongly urges upon the Congress the propriety of appointing Health Officers, and of adopting the most effectual measures to secure the publication of their periodical reports amongst the people of each locality, showing the state and progress of their sanitary condition.

8. They suggest that in every State quarterly returns should be published of the marriages, births, deaths, and prevailing epidemics of every district, as well as *annual* returns of the deaths and fatal diseases at each quinquennial period of life. The tables should, in all cases, be accompanied by popular and scientific reports.

9. In large cities, *weekly* tables, such as those of London, should be published.

10. In this manner the sanitary condition of each part of the population will become known, and the efficacious measures which may be discovered in any country can be applied in all others ; so the health of the human race will be improved, and each nation will get its full share of the benefit.

The Section cordially adopted Dr Farr's recommendations, with one or two slight modifications, involving the quarterly and monthly publication of reports referred to in the eighth proposition.

Mr Hart proposed, as an important addition, that returns of sickness should be furnished in a manner similar to the returns of mortality. He called attention to the very valuable returns of sickness which for some time were published by the General Board of Health, having been prepared by the Metropolitan Medical Officers of Health, at considerable expense to themselves ; and regretted that financial considerations should have induced the Government to discontinue their publication.

Dr Ballard observed, that the importance of such a publication could not be over-estimated, and the withdrawal of the Government aid in this matter had been a source of great discouragement to the Health Officers of the metropolis. Returns of mortality in no measure afforded an accurate means of ascertaining the relative prevalence of diseases, as their fatality varied, not only *inter se*, but at different seasons.

These views were supported by Dr Tripe and other members of the Section, and it was determined that a recommendation to this effect should be made to the British and foreign Governments.

The paper of Mrs M. A. Baines, on Wet Nursing, read by Dr. M'William, opened with the statement that out of 100 children in Paris suckled by their mothers, the deaths are 18 ; while of those wet-nursed they are 29 per annum. Besides the mortality amongst children of mothers belonging to the middle and upper classes, it may be fairly assumed that the children of wet-nurses form a very large proportion of those who die prematurely from this custom, whether those deaths are recorded as caused by *want of breast-milk*, or classed under *convulsions*, or any of the numerous disorders arising out of ignorant management, or wilful—*i. e.*, culpable—neglect. It is not an uncommon occurrence for the name of one child to be on the books of two, three, or even four burial societies. Where this is the case, suspicion must naturally be attached to the motive of the parent, parents, or nurse ; and when death occurs under such circumstances, investigation should take place as to the cause, and a *reliable* medical certificate be obtained. It would be interesting and important to know, in connection with the present subject, how many of the mothers of "still-born" children follow the occupation of wet-nursing—*i. e.*, how many had decided upon taking up that vocation before the birth of the "still-born." For the consideration of the Sanatory Section of the Congress, a few practical suggestions were offered relating to some simple means by which very valuable, if not complete, information might be attainable.

1. Members of the medical profession in obstetrical practice might be recommended or required to keep notes with reference to the number of their patients who employ wet-nurses, the fate of the infant so reared, and that of the woman's child. This information should embrace the first twelve months after birth, supposing the children should survive so long.

2. The Medical Officers of Health in each district might undertake the duty of collecting the information desired, so that they might furnish to the Registrar-General the necessary figures and facts.

3. The Registrars in the various districts and provincial towns might be instructed to ascertain the number of children who die under one year old, such children having been consigned to wet-nurses, or discarded by their mothers to enable them to do duty as wet-nurses.

It is a fact, to which the secretaries of burial clubs can testify, that many of the infants entered on their books, and who die prematurely, are the children of wet-nurses put out to "dry-nurse," and are there made use of as the victims and innocent agents of a profitable speculation by their ostensible but inhuman "guardians."

Dr Ballard called attention to the fact that England is almost the only country in which still-births are not registered. He complained that the Health Officers were not officially entitled to communicate with the Coroner on the subject of suspicious deaths, and that this important duty was left wholly to the discretion of a beadle. Three deaths of infants were registered from one house in his district, within a fortnight, as occurring from hydrocephalus—a disease of such rarity that no medical man could credit the record. He strongly suspected that these deaths were caused by opium, in some of the forms employed by the lower classes for quieting children.

Dr Milroy's paper on the International Registration of Epidemics proposed an inquiry which has not yet been attempted—the notation and record from year to year of some of the principal epidemics in the different countries of both hemispheres. The researches of inquirers having to the present time been necessarily confined to their own country, and often only to one division of it, it is obvious that unless like researches are being carried out simultaneously in other countries, contiguous and more remote, some most interesting problems of epidemiology—such as the migratory course of certain epidemics, their recurrence at irregular intervals, their subsidence at one time and their reappearance at another—can never be hoped to be elucidated. It is worthy of note that the last sixteen or eighteen years have afforded some most remarkable instances of the kind. What has been done of recent years with so much advantage by the synchronous observation and record in different regions of the phenomena of meteorology, magnetism, and other branches of the physical sciences, might probably be undertaken with similar benefit by the registration on the same plan of epidemic statistics. From the aid which the Earl of Shaftesbury gave to the Committee, a large amount of valuable data respecting recent epidemics in most parts of the world has been received through the Foreign and Colonial Offices, and from the Medical Departments of the Army and Navy. The institution from this time of a systematic annual record of certain epidemics occurring in the various countries represented at this Congress, would be the means of obtaining such diversified information as, when collated at the next meeting of the Congress, might serve to throw much light on the natural history of that class of diseases, and lead to results useful alike to science and humanity. Epidemic storms may yet be traced and indicated in much the same way, and with like beneficial effects, as ordinary meteoric storms have been of recent years by Sir W. Read and other good observers. The diseases to which attention is called are, typhus and typhoid fever, intermittent and remittent fever, yellow fever, cholera, dysentery, influenza, small-pox, and perhaps also scarlatina and diphtheria, with other maliguant forms of sore-throat. The points in their history specially deserving to be noticed are—1. The period of their commencement ; 2. The total number of deaths, and, as far as possible, of attacks ; 3. The general sanitary topography of the towns or districts ; 4. The precursory state of the public health for one or two months ; 5. The date of the last epidemic, and also the extent and fatality of that invasion and of the present one, so that a comparison may be made between them.

Dr M'William stated that yellow fever had of late years shown itself at altitudes and in latitudes never before invaded, and observed that it was not impossible that England may some day be visited with this scourge. He recommended that some responsible persons should in all ports note the first occurrence of this disease and of cholera, recording the first case, and the conditions under which it appears.

Dr Delany, a coloured gentleman from Canada, made some important observations on the spread of cholera.

Dr Neumann referred to leprosy, or "spedalskhed," by which term it is well known in Sweden and the northern countries of Europe. He stated that Dr Virchow, of Berlin, was engaged in making inquiries on this subject, and suggested that the disease may also occur in the northern parts of Scotland and the Scottish islands, and he begged that inquiries might be made on this point.

Sir David Brewster, in a note to Dr Farr, suggested that returns regarding colour blindness and certain diseases of the eye, such as conical and cylindrical cornea, &c., should be obtained by the Section. He

had intended to submit a paper on the Influence of Light as a Curative Agent, and on the Development of Animal Life, which he was unable to complete in time. His wish was to call attention to the method of throwing light into the windows of houses in narrow streets and lanes, where hundreds of human beings in the principal cities of Europe carry on their occupations in what seems to a stranger almost total darkness.

Professor Simonds laid before the meeting the importance of ascertaining the extent and fatality of epizootic and other diseases amongst those animals that are ordinarily used as food, which could be easily carried into effect by the appointment of veterinary surgeons or other officers in the various countries represented in the Congress.

Dr Jarvis, of the United States, recommended that the superintending officers of lunatic asylums in all countries should publish their reports on a uniform plan.

Dr Neumann, of Berlin, read a paper on the Prevalence of Cholera in Prussia from 1831 to 1855, which was illustrated by the exhibition of three maps, specially designed to show the origin and progress of the disease in that country, and which were very highly appreciated by the Section.

Dr M'William proposed, and it was recommended by the Section, that the various Governments represented by delegates should adopt a uniform method of obtaining statistical information as to the health of seamen engaged in the mercantile marine.

The business of the Section then concluded.

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL REFORM ASSOCIATION.

To the Editor of the Medical Circular.

SIR,—I must again ask the favour of your allowing me through the medium of your pages to address the Poor-law Medical Officers. Since my last communication, I have received a letter from Mr Pigott, who stated he had met with difficulty in getting the Bill drawn, as he did not wish to incur an expense of 20*l*. I was obliged to fix a limit to the amount for which I should render myself liable: the Poor-law Medical Officers must therefore blame themselves for the loss of the Bill this Session; for had they enabled me to give a *carte blanche* to Mr Pigott, the Bill would have been speedily drawn; but the only subscriptions I have received this month have been 10s. 6d. from a Poor-law Medical Officer, and 10s. from a Medical gentleman unconnected with the Poor-law; and in the previous month I received less than 3*l*.

Mr Pigott concludes his letter by saying, "I fear I must follow the advice generally given me by my friends here (House of Commons), namely, to lay a good Bill on the table this Session, and then work it through next: I like the principle of the Bill," &c. &c. I regret the apathy of the Poor-law Medical Officers as a body, though I can quite understand the motives that influence many of them. I have ascertained each Poor-law Medical Officer's salary under the present *régime*, and calculated what it would be under the proposed plan. I have also ascertained the number of patients attended by each Medical Officer; and when I narrate there are 360 Medical Officers who attend less than 50 patients each annually, and as many of these officers have as much or more than 20s. for each case they attend, it will not be surprising that they are either indifferent or adverse to the proposed change. Again, there are 94 Medical men who have more than 1,500 patients annually under their charge; some of these attend from 2,000 to 5,000 each, and one has upwards of 10,000 patients. Some of these gentlemen object to the proposed limit of 1,500 patients, and one has written to me that many of the London men will oppose the Bill unless this clause be withdrawn; the old adage "Every man for himself" is here verified—to please all is impossible. The variations between these extremes may be interesting to your readers: 525 Medical men attend between 50 and 100 patients each annually, 744 between 300 and 500 patients, 442 between 500 and 1,000 patients, and 176 between 1,000 and 1,500 patients. On a future occasion I will lay before your readers a continuation of my calculations, if you will kindly allow me to do so; though you perhaps, like my colleagues, may be tired of the subject: if so, I must succumb to the fate which many wiser men than myself have experienced.

I am, Sir, &c.,
RICHARD GRIFFIN.

12 Royal terrace, Weymouth,
25th July, 1860.

P.S.—Since the above was written, I have seen the letter of Mr Nicholas in your journal of this day. The objection to his plan is, that it raises the salaries far higher than mine, and also raises a distinction between the metropolis and the provinces, and therefore incurs the risk of a clause being inserted to except the metropolis from the operations of the Bill. Mr Nicholas says the highest average number of patients attended by Medical men is 377, and therefore assumes that number may be legislated for; but, had he carefully studied the figures, he would have found that 2,139 Medical men attend annually less than 300 cases each, and that 1,260 attend far higher numbers, and some of these upwards of 3,000 cases each. Surely he would not give them more than 5s. for each case they attend; if he would, I fear the Guardians would not quietly acquiesce in such an arrangement.

POOR-LAW MEDICAL SERVICE.

To the Editor of the Medical Circular.

SIR,—At this advanced period of the Session, when scores of Bills in every stage of progress are daily being thrust aside on account of the crowded state of public business, it is not likely that Mr Griffin's new Bill for Poor-law Medical Reform will make much progress, even should it be allowed to creep in: there is, therefore, no immediate hurry to discuss its provisions; indeed, we have not yet seen a draught of it. My object in adverting to it just now, is to offer some comments upon a letter in your last number from Mr Nicholas of Wandsworth, who, in stating the case of the Metropolitan Surgeons, does so, I think, unfairly as regards his brethren in the country. He admits *in limine* that the circumstances under which the provincial men and the metropolitan severally discharge their duties are very different—few cases and large space for the former, numerous cases and small space for the latter. But, while fully admitting this, he does not carry out the legitimate inference, viz., that the payment per case should be greatly more where the cases are few and widely spread, than where the locality is densely populated; for, besides the expense of horses, time is a most important element in the calculations of the country surgeon. There cannot be a doubt, that one parish surgeon may see twenty cases in a small compass, in the same time that it will require to visit one case four or five miles distant: therefore, I contend that 1s. 6d. a case does not fairly represent the difference between metropolitan and country cases; it is one case at 5s. to twenty at 3s. 6d.—and though that may not always be the proportion, yet, even taking Mr Nicholas' average of numbers of 377 in country districts and 1,429 in metropolitan ones, it would make the pay of the latter more than double that of the provincial men. It is evident, therefore, that we cannot give up our *mileage*, as Mr Nicholas proposes; nor, indeed, is there any reason why we should, as it is nothing more than a reasonable demand, and would be a check upon the Guardians making the districts too large, as they are very much disposed to do. If mileage is not stipulated for, the cases must be paid for at an increased rate in straggling districts, and according to numbers; say, up to 200 at 10s.; 300, 7s. 6d.; 400, 5s; and so diminishing to 3s. 6d. I do not at all grudge my metropolitan brother 3s. 6d. a case upon his large average, but he must allow me a large difference upon my smaller one.

I am, &c.,
AUDI ALTERAM PARTEM.

ST GEORGE'S HOSPITAL.

To the Editor of the Medical Circular.

SIR,—In the remarks on this subject which appeared in the last number, the Governors of the Institution are spoken of as being amenable to the charge of improvidence and a wasteful disposal of the funds: but the body of Governors who pay their subscription take no part in the management of the Hospital, which, as the "Governor" who addressed the 'Times' justly observes, "practically rests with a very small number of individuals, (the fifteen or sixteen gentlemen who are *habitués* of the weekly and quarterly Boards), although it is theoretically supposed to be under the control and supervision of many hundred Governors, over whom, however, the blame of any mismanagement can be spared should anything go wrong."

Another 'Times' correspondent, who, it appears, was requested to reply to this letter, admits that a worse choice of a defender could scarcely have been made, inasmuch as he cordially concurs in the justness of the "Governor's" observations. He comments upon the comparatively little support the hospital receives from its wealthy neighbourhood, many of the residents being liberal contributors to charitable objects and even *to other hospitals in London*. May not this circumstance be ascribed to the same cause that induced a late respected Treasurer (Mr Holland) to resign, and to record his disapprobation of the system pursued in the Minutes of the Board? It must be obvious that those residing in the neighbourhood would be more cognisant of the reprehensible proceedings of which St George's has been on more than one occasion the theatre, than distant subscribers; and some have, doubtless, on that account withheld the cordial support that would otherwise have been given. The "Governor" says that, as far as he knows, there are no grounds for imputing to any one malversion of the funds or jobbing. Improvidence and a reckless expenditure of public money have, however, not unfrequently served as a cloak for malversion. What other term can be given, for instance, to the grant voted by a Board in 1848 of 200*l*. a year for the support of the Anatomical School in Kinnerton street, which was declared at the time by eminent Counsel to be an illegal appropriation of the hospital money? This sum, however, is still paid, notwithstanding that the school for several years past has been able to cover its own expenses by the receipt of pupils' fees. (*a*)

A glaring instance of the embezzlement of the funds of a charity is recorded in the journals of last week; the Vice-President and Manager of the Liverpool Northern Hospital—a man of independent fortune, and moving in the first society of that city—having been committed for trial, for forging receipts, &c., and embezzling money to the amount of 4,000*l*.

It is greatly to be regretted that there exists no efficient legislative supervision of the pecuniary as well as of the general management of charities for the relief of the sick poor, by means of which these noble institutions might be made more conducive in effectually carrying out the purposes for which they are designed, and the benevolent intentions of their supporters.

Yours, &c., EDWIN LEE.

69 Pallmall, July 26.

[There is no subject connected with hospital management of greater importance than that referred to in Mr Lee's letter. Would it not be advisable to institute an annual Government Audit of Charity Funds, to be published for the information of the subscribers? We are inclined to think that subscribers would give their money with more confidence if they felt that the Board of Governors was under the check of a higher power.—ED. MEDICAL CIRCULAR.]

SPECIAL HOSPITALS.

(We have been requested to publish the annexed statement, which, in addition to the signatures attached to it, has been signed by the majority of the Physicians and Surgeons of the London Hospitals.—ED. MED. CIRCULAR.)

We, the undersigned, are of opinion that much detriment to the public and to the Medical Profession arises from the modern practice of opening small Institutions under the name of Hospitals, for particular forms of disease, in the treatment of which no other management, appliance, or attention is required, than is already supplied in the existing General Hospitals.

The practice is injurious—first, because in the maintenance of numerous small establishments, the funds designed for the direct relief of the sick

(*a*) The particulars of this transaction are stated in the 'St George's Hospital Medical Staff,' and the names of the Committee of Management of St George's are given in the 'Additional Notes' which have recently appeared.

poor are wasted in the useless multiplication of expensive buildings, salaries, and hospital appliances, and in the custom of constantly advertising to attract public attention.

Secondly, because the public is led to believe that particular classes of diseases can be more successfully treated in the small special Institutions than in the General Hospitals; an assumption directly contrary to evidence, the fact being that the resources of the General Hospitals are in every respect superior to those of the special Institutions alluded to.

Thirdly, because it is essential for the interests of the public, with a view to the efficient education of Students preparing themselves for the practice of the Medical Profession, that all forms of disease should, as far as possible, be collected in the General Hospitals to which Medical Schools are attached.

As an example that the evil referred to is increasing, we regret to observe that an attempt is being made to set on foot a Special Hospital for the treatment of Stone and Diseases of the Urinary Organs. We desire to express our opinion that such an Institution is especially unnecessary: the existing General Hospitals provide ample accommodation for the treatment of all these maladies; *no case is ever refused admission into them;* there are no diseases which receive more care, attention, and skilful management; and there are no men in this or any other country who have greater experience in treating them than the Surgeons of our General Hospitals.

Signed by

Sir Benjamin C. Brodie, Bart., President of the Royal Society.
Joseph H. Green, F.R.S., President of the Medical Council.
Thos. Mayo, M.D., F.R.S., President of the Royal College of Physicians.
J. F. South, President of the Royal College of Surgeons.
James Moncrieff Arnott, F.R.S., late President of the Rl. College of Surgeons.
Sir Charles Locock, Bart., Physician-Accoucheur to the Queen.
P. M. Latham, M.D., Physician-Extraordinary to the Queen.
Thomas Watson, M.D., F.R.S., Physician-Extraordinary to the Queen.
W. Gibson, M.D., C.B., Director-General of the Army Medical Department.
Sir John Liddell, C.B., F.R.S., M.D., Director-General of the Navy Medical Department.
Sir J. Ranald Martin, C.B., F.R.S., Physician to the Council of India.
B. G. Babington, M.D., F.R.S., President of the Epidemiological Society.
Sir Chas. Hastings, M.D., President of the British Medical Association.
S. H. James, Esq., F.R.C.S., Consulting Surgeon to the Devon and Exeter Hosp.
J. A. Symonds, M.D., Consulting Physician to the Bristol General Hospital. And many others.

The following letter accompanied Sir Benjamin Brodie's signature:

"Broome Park, Betchworth, Surrey,
"July 16, 1860.

"Dear Sirs,—Agreeing in the views expressed in the paper which you have sent me, I am happy to add my signature to it.

"An exception, indeed, may be made, on grounds which meet with the general concurrence of the Profession and the public, in regard to Ophthalmic Infirmaries. Otherwise it seems to me there are very great objections to the establishment of special hospitals for the treatment of particular diseases.

"First,—Diseases generally are so connected with each other, and a knowledge of one is so necessary to the right understanding of another, that no one who limits his attention to any given disease can be so competent to investigate its nature, and to improve the method of treating it, as those are who have a wider field of observation, and who are better acquainted with general pathology.

"Secondly,—The effect of establishing special hospitals and infirmaries is to abstract particular classes of disease from the general hospitals, and thus to prevent the students of those hospitals from having the opportunity of studying certain branches of their Profession, an acquaintance with which is necessary to make them useful practitioners afterwards.

"Thirdly,—The system of establishing special hospitals, which now prevails, is a source of much unnecessary expense to the public; each one of these, however humble it may be, requiring a separate house, and a separate establishment of matron, nurses, and servants. At least two-thirds of the expense thus incurred would be saved, if the patients who are there admitted were sent to the existing general hospitals instead; and it cannot be said that in these last there is no room for their reception, there being several which are languishing for want of funds, with their wards empty because the means of supporting them have been drawn away to other institutions. "I am, dear Sirs,

"Yours truly,
"Benjamin C. Brodie.

"To the Members of the Deputation appointed by the representatives of the Medical Staffs of General Hospitals."

OUR NOTE BOOK.

ON THE EMPLOYMENT OF IODIDE OF POTASSIUM IN DISEASES OF THE BRAIN IN CHILDREN.

Dr John Coldstream, says: It is now upwards of twenty years since iodide of potassium was commended by Rœser and others, as a remedy of special power in hydrocephalus. It is surprising how few seem to recognize its value, and what slight references are made to its employment in the various works on the diseases of children. In all cases when, from the course of the symptoms, there is reason to believe that the central organs of the nervous system, or their envelopes, are in any degree affected with strumous inflammation, (tubercular cerebritis, or meningitis,) or its consequences, after moderate purgation, the writer is in the habit of employing the iodide of potassium in doses of from half a grain to three grains, every three or four hours, in some carminative water, and continuing it for many days, according to the symptoms, or until convalescence is fully established; and with the occasional use of blisters to the shaven scalp, he believes he has produced more prompt and decided effect upon the disease than by any other treatment. When the opportunity has been afforded of commencing the use of this remedy early, it has appeared to arrest the progress of the disease *rapidly*, so that the effects of effusion, indicated by squinting and convulsions, have not supervened. In less favourable circumstances, where considerable prostration had succeeded great febrile action, where starting and squinting had become prominent symptoms, in not a few instances, the free use of iodide of potassium has been followed by amendment and recovery. In such cases it should be given in large doses, even to four grains several times a day, to children of from four to eight years of age.

The medicine is very seldom refused by the patient, nor does it increase the nausea so frequently existing in the earlier stages of the disease; nor has it induced salivation, which seems sometimes to follow its use in other ailments. Although it is more especially useful where there exists more or less of the scrofulous diathesis, yet it has been found of service in cases where no taint was present.

The writer is not prepared to assert that this agent is more useful than calomel in *all* cases of inflammation of the brain and its appendages. When we have to treat robust and full-blooded children, in whom there is reason to believe that the threatened disease of the nervous system stands more or less directly connected with preceding disorder of the digestive organs, there is no doubt of the superior efficacy of the mercurial treatment, combined with antimonials and salines; but when, after having duly administered these remedies, symptoms of cerebral disorder continue, the iodide should then be employed. The writer, in concluding, is satisfied that the iodide of potassium never produces any bad effects, though it may fail to do good.—'Edinburgh Medical Journal,' Dec. 1859.

REMARKS ON EXCISION OF BONE IN GENERAL, AND ESPECIALLY OF THE KNEE-JOINT.

The difficulty of forming a correct estimate of the injuries requiring excision in preference to amputation, accounts for the restricted performance of the removal of portions of bone. On the field of battle it is seldom resorted to; although in the war of the Duchies, Stromeyer and Langenbeck did so with success. Various foreign works on the subject, and especially a memoir of Professor George Adelman, of Dorpat, recently translated into French by M. Bénard ('Archives Belges de Méd. Mil.'), seem, however, to show that, when excision is performed at leisure and under favourable circumstances, its results are not on an average more fatal than those of amputations or disarticulations.

The first part of the paper refers to thirty operations of excision performed for various diseases of the bones of the upper extremity: 6 cases terminated fatally, and in 18 the functions of the limb were preserved.

Resection of the knee-joint has been so severely judged by most surgeons, that Professor Adelman has deemed it desirable to gather on this point the most extensive and accurate information possible. The number of cases he has collected amounts to 163. The procedures adopted may be classed under three heads: 1. Two lateral cuts united by a transverse incision below the patella. 2. A semi-lunar incision running below the patella, from one condyle to the other. 3. A crucial incision. The result of these various processes is the same, and therefore, in M. Adelman's opinion, the surgeon may, according to circumstances, have recourse to either. 86 of these cases terminated favourably; 51 patients died, 24 of whom were carried off by puriform absorption. M. Adelman recommends the removal of the patella when it is diseased only; in this respect, his opinion is at variance with that of Messrs Fergusson, Canton, and Price. — 'Journal of Practical Medicine and Surgery.'

ERYSIPELAS OF INFANTS. POWDER OF STARCH, TAN, AND CALOMEL.

The dangers which attend the erysipelas of new-born children, especially when it originates in the umbilical cicatrix, are well known. In this case, says the 'Gazette des Hôpitaux,' Dr Legroux has for some time used, in his nursling ward at the Hôtel-Dieu, a method which appears to yield most satisfactory results.

It consists in smearing the diseased parts with glycerine, and applying a powder composed of equal parts of starch, tan, and calomel. The dressing should be renewed two or three times in the course of the twenty-four hours.—'Journal of Practical Medicine and Surgery.'

ULCEROUS OZENA. ASSOCIATION OF TONICS AND CHLORATE OF POTASH IN THE TREATMENT.

The 'France Médicale' records the case of a girl, who, having suffered from glandular enlargement, and other symptoms displaying a lymphatic predisposition, evinced unmistakeable signs of ozena. A fetid and copious nasal discharge was present, which became particularly intolerable at the period of menstruation. The Schneiderian membrane was red and slightly ulcerated. Under these circumstances, the medical attendant prescribed the following course of treatment:

1. To sniff up seven or eight times daily the following solution:

R. Potassæ chloratis . . . 2 drachms.
Aq. destill. . . . . 8 ounces.

2. Morning and evening, one pill of—

R. Extr. cinchonæ . . . . . 1 gr.
— gentianæ . . . . . 2 gr.
Ferri sesquicarbonatis . 3 gr.

3. Bitter infusions, &c.

Under the influence of the above medication, the discharge decreased, and at the expiration of two or three weeks the fetor had lost much of its intensity. Three months had barely elapsed when all trace of the disease, which had lasted eight or ten months, altogether disappeared.—'Journal of Practical Medicine and Surgery.'

CHLORODYNE: ITS HISTORY, PREPARATION, PROPERTIES, THERAPEUTIC EFFECTS, DOSES, &c.

History.—Chlorodyne was invented in the year 1848, by Dr Browne, while officiating in his medical capacity during the prevalence of cholera and diarrhœa amongst our troops in India, and was introduced to the notice of the Faculty in this country by him as "combination of perchloric acid with a new alkaloid."

Preparation. — From Dr Ogden's analysis, it appears to be composed as follows:—Chloroform, six drachms; tincture of capsicum, half a drachm; oil of peppermint, three drops; muriate of mor-

phia, eight grains; perchloric acid, twenty drops; Steele's hydrocyanic acid, twelve drops; tincture of Indian hemp, one drachm; treacle, one drachm. Dissolve the morphia in the perchloric acid; then add the tincture hemp, capsicum, peppermint, and chloroform, and lastly the treacle and prussic acid.

Properties. — Chlorodyne is a volatile liquid, possessing a pungent smell and taste. It is soluble in alcohol, but insoluble in water; but may be conveniently administered in that liquid by suspending it in a little mucilage. The alkalies and alkaline salts decompose it. In colour it is dark brown, and in weight equal to twice its bulk in water. It is anodyne, sedative, diaphoretic, astringent, antispasmodic, diuretic, &c. Unlike the preparation of opium, it does not produce headache, giddiness, prostration of strength, nor stupor; but in large doses, and from a constipated state of bowels, it is liable to produce nausea, which in the former case may be relieved by a small dose of sal volatile, and in the latter by recourse to aperients.

Therapeutic Effects.—The changes produced by this preparation on the system are: first, a gentle heat at the stomach, followed by a general glow and total absence of pain; second, a calm and refreshing sleep; and third, an increase in the pulse, from a "small, weak, thready, hurried, or bounding one, to a full, yielding, elastic, natural sort of one, decreasing in frequency of beats as well as resistance to a healthy condition." — 'Chemist and Druggist.'

RADICAL CURE OF HERNIA.

Dr Choppin, referred to, is an earnest advocate of the Wurtzer plan of operating for the radical cure of hernia. He has operated many times with success, and has demonstrated, by post-mortem examinations of subjects operated upon years before, that positive occlusion of the canal had taken place; thereby rendering the recurrence of the hernia impossible. The Editors of the 'Medical News and Hospital Gazette,' referring to Dr Choppin's operations, and his lecture upon this subject in the Charity Hospital, say, "We have several times before called attention to this most valuable operation, and offer no apology for repeating our opinion, that it is one of the most important surgical innovations of the age, if not absolutely the most important." Several eminent surgeons have ridiculed this operation; but, really, we hope the views and experiences of Dr Choppin may be proved to be correct by subsequent clinical observation.

In the 'Medical Press' for February 11th, Dr J. W. Rosebrugh reports a case of hernia apparently cured, after two operations after the plan of Wurtzer. He says: "The inguinal canal was so large that *three* good-sized fingers could be introduced into it." Hopes of success were entertained after the first operation, but after a month the patient felt something give way, and a fold of intestine descended into the scrotum. On reducing the hernia again, "the canal was found to be so small that the point of one finger could scarcely be insinuated into it." Encouraged by a partial success, the operation was repeated, and three months after there is every porspect of a radical cure.

Prof. J. C. Nott, of Alabama, writing from London to the 'New Orleans Medical and Surgical Journal,' and speaking of this operation, says: "In Paris, I talked with Velpeau—the Nestor of French Surgeons—with Nelaton, and others, and they all say that Wurtzer's operation, or any other on similar principles, cannot be relied on, the disease returning in the great majority of instances. In fact, the operation is scarcely performed at all now in Paris." Opposed to these views, we may instance the following, as the most recent, in addition to those previously referred to. One of the Editors of the 'New Orleans Medical News and Hospital Gazette,' in the February issue, says: "The fact that the radical cure of hernia can be nearly always accomplished by the method under consideration is no longer to be disputed, and he who sneers at it is only furnishing a stick with which to have his own head broken."

In the 'Charleston Medical Journal and Review' for January, Dr T. L. Ogier reports twelve successful operations by Wurtzer's method, and he says he has performed nineteen other successful operations, not included in his report. Dr Ogier concludes his report thus: "Recent cases, in subjects under forty years of age, are always successful, and, as far as my limited experience goes, quite free from danger."

In the paper of Dr Rosebrugh, in the 'Medical Press,' the Author says he was not aware that the operation of Wurtzer had ever been repeated in the same individual. In the 'Medical Times and Gazette' for August 6th, 1859, Dr Redfern Davies reports forty cases of this operation, in *five* of which the operation had to be *repeated*. He says, "Where the rings are very large, and relaxed, the operation is sometimes unsuccessful, and has to be repeated." Out of Dr Davies' forty cases, "but two were complete failures, and of these one was owing to supervention of small-pox."

If the operation for the radical cure of hernia is seldom resorted to in Paris, as we are led to believe by reports, it is frequently and successfully performed both in England and America.—'American Medical Monthly.'

IODIZED OIL OF JUNIPER BERRIES.

Dr Heller, of Vienna, found the use of this solution preferable to that of the ointment of iodide of potassium (which shows no action on the system, except when it has become yellow and decomposed, and contains free iodine), and of the tincture of iodine, which sometimes in prolonged use produces very disagreeable effects. Iodine is readily soluble in oil of juniper berries, but must be mixed with it cautiously, and in small quantities at a time, in order to avoid explosions. The solution is brown, and loses its colour by standing, according to Dr Heller; though a solution of 20 grains of iodine in 1 oz. of oil, which had been prepared for an experiment in order to determine the percentage of solubility, had not become colourless after several months. The preparation must be considered a chemical compound; for there is no free iodine detected in it by a solution of starch. It has, furthermore, not the offensive smell of iodine; it does not stain or destroy the epidermis like the tincture of iodine, and after its application iodine can be found in the urine as well as in the saliva of the patient. Oil of lavender may be substituted for oil of juniper berries.—'London Medical Review.'

Births, Marriages, and Deaths.

BIRTHS.

BLACK.—July 19, at Amelia place, Southgate road, the wife of Robert J. Black, M.D., of a son.

PEMBERTON.—July 22nd, at Temple row, Birmingham, the wife of Oliver Pemberton, Esq., M.R.C.S., of a daughter.

TRAER.—July 19, at Hans place, the wife of J. Reeves Traer, Esq., F.R.C.S., of a son.

MARRIAGES.

FARQUHAR—FISHER.—July 18, at St Mark's Church, Pennington, Hampshire, Thomas Farquhar, M.D., H.M.'s Bengal Army, to Charlotte, daughter of the late Captain A. S. Fisher, H.M.'s 72nd Highlanders.

MACROBIN—CATTLE.—July 24, at the parish church, Kirkleatham, Yorkshire, J. Macrobin, M.D., Professor of Medicine in the University of Aberdeen, to Eleanor Isabella, eldest daughter of the late Christopher Cattle, Esq., of Easingwold.

DEATHS.

BARTLIFF.—July 14, at New Malton, Yorkshire, George Bartliff, L.R.C.P. Edin., M.R.C.S. Eng., L.S.A. Lond., aged 51.

BELL.—July 14, at Great Malvern, Frederic Bell, of Aldborough, Suffolk, M.R.C.S. Eng., L.S.A. Lond.

BOOTH.—May 25, at Dinapore, of cholera, Edward Booth, Surgeon of H.M.'s 73rd Regiment of Foot.

GAIRDNER.—July 24, at Northumberland street, Edinburgh, Mrs Gairdner, the wife of Dr John Gairdner, F.R.C.S.

GLADSTONE. — Recently, William Gladstone, Deputy-Inspector General of Hospitals and Fleets (Retired).

HILL.—July 22, at Wotton-under-Edge, Gloucestershire, William James Hill, M.R.C.S. Eng., L.S.A. Lond., aged 41.

HINGSTON.—July 13, at his residence, Liskeard, Cornwall, Richard Hingston, Surgeon (in practice prior to 1815), aged 81. He was one of the oldest inhabitants of the town, and practised his Profession there for upwards of half a century.

MOLINE.—June 17, at Cawnpore, James Prichard Moline, Staff Surgeon, aged 44.

MOUSLEY.—July 18, Thomas Mousley, of Ellesmere, Shropshire, L.S.A. Lond., aged 52.

O'BRIEN.—May 10, at Calcutta, Thomas O'Brien, L.R.C.S. Ireland.

SILVER.—July 24, at Duncan terrace, Islington, John Bye Silver, Surgeon, late of the Bombay Army.

SOLE.—June 27, of dysentery, on board the Peninsular and Oriental Company's steamer 'Benares,' John Sole, Surgeon, Royal Navy, late of the 'Retribution' steam frigate.

WENDELL.—July 11, at his residence, 31 Pierrepoint street, Brooklyn, New York, Matthew Wendell, M.D., aged 81.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College, at a meeting of the Court of Examiners, on the 20th inst.: — William Atkinson, Wallingford, Berkshire; Edward Henry Beaman, Up Holland, near Wigan, Lancashire; Robert Byers, Pateley bridge, Yorkshire; Francis Richard Cruise, Dublin; Frederick Deyns, North Walsham, Norfolk; Nathaniel Batt Grigg, Salisbury; Henry Lewis Harper, St Luke's Hospital, Old street; Thomas I'Anson, Newcastle-on-Tyne; Alfred Sinclair Kingdon, Bideford, Devon; Edward William Major, Exeter, Devon; Bartholomew Shaw, Cambridge road, Bethnal green; James Lodge Wilson, Nottingham.

APOTHECARIES' HALL.—The following gentleman passed his examination in the science and practice of Medicine, and received his certificate to practise, on Thursday, July 19th, 1860: Lionel Burrell, Westley, Bury St Edmunds; James Neale Earle, Brunswick street, Dover road; Stenard Edye, Exeter; Frederick Hall, Banger, North Wales; James O'Brien Kough, Shrewsbury; John Lakeland, Manchester; Isaac Merris, The Cliff, Lewes, Sussex; William Park, Ulverstone, Lancashire; John Ullathorne, Heighington, Durham.—The following gentlemen also on the same day passed their first examination:—Thomas Dobson, Charing-cross Hospital; M. Hale Humphreys, Charing-cross Hospital; Morris Jones, Aberystwith; George Okell, King's College; Caleb Carey Richards, King's College; Thomas Savage, the General Hospital, Birmingham; William Watson, University College.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen, having finished the course of examinations, were admitted Licentiates of the College during the recent sittings of the Examiners:—John Baxter, New Brunswick; Robert Erskine, Ayr; Alexander Grant, Aberdeenshire; John Greig, Kincardineshire; Arthur Renwick, Sydney, New South Wales; Alexander Scott, Aberdeen; Walter Scott, Stirlingshire; William Sheriff, Northumberland; George Stevenson Smith, Ayr; Henry Cunard Stevenson, New Brunswick.

APPOINTMENTS.—Dr Robert Lee has been elected one of the three Examiners in Midwifery in the Royal College of Surgeons, in the place of Dr Charles West.—Mr Luther Holden, F.R.C.S., was unanimously elected Assistant-Surgeon to St Bartholomew's Hospital, on the 25th inst., in the vacancy occasioned by the resignation of Mr A. M. M'Whinnie.

WOMEN AND CRIME. — On criminal charges more women are acquitted than men. Of the men who were proceeded against summarily in the year ending at Michaelmas, 1859, 68·7 per cent. were convicted by the magistrates; of the women, only 53·9 per cent.—a difference of nearly 15 per cent. Mr. Redgrave states that it is so throughout the criminal statistics, and therefore it must extend to the graver offences; but in compiling the 'Judicial Statistics,' he has distinguished males from females in the commitments for indictable offences, but not in the convictions. The cause he assigns for this good luck of women is lenieney towards their sex; so that Justice is not so blind as she is painted.

LONGEVITY IN A LUNATIC.—James Coyle, a patient at St Patrick's (Swift's) Hospital, Dublin, died on the 17th inst., in the 106th year of his age. He was admitted May 28th, 1802, in his forty-eighth year, and was for upwards of fifty-eight years an inmate of the institution.

SOCIAL AND SANITARY SCIENCE.—The Social Science Association will held its meeting shortly in Glasgow; a full attendance is anticipated. The next meeting of the International Statistical Congress will be held in Berlin, probably at the end either of two or three years.

THE DEATH BY OVERDOSE OF HYDROCYANIC ACID.—The painful charge against Mr. Bull, a Surgeon, of Lewes, of manslaughter, for neglect in administering to his mother an overdose of hydrocyanic acid, was tried during the week at Lewes. Mr. Bull had watched his mother carefully and affectionately through illness, and administering, as he believed, seven drops of dilute hydrocyanic acid, had the unhappiness to see the dose prove fatal. The charge of criminal neglect was not sustained by the evidence, and the jury immediately returned a verdict of "Not Guilty." Some important points were prominently brought forward in the course of the evidence relating to the variable strength and doses of the preparations of hydrocyanic acid commonly employed, to which it will be desirable again to return.

AID TO THE WOUNDED IN ITALY.—The 'Unita Italiana' relates that Carini, a philanthropiat of Brescia, having bequeathed a sum of 12,000 fr. to the college of that place, the interest of which was to be devoted every year to the purchase of a gold medal of the value of 500 fr., and two silver ones, to be given to those persons who should distinguish themselves most by acts of charity, the gold medal this year was awarded to Angelina Torinelli, a young female of Brescia, who, with the assistance of seven of her companions, organized, furnished, and directed an hospital for thirty-four wounded persons. The generous young girl said that the merit and the medal belonged as much to her companions as to herself, and begged that the value of it should be sent in their joint names to Garibaldi, as well as a further sum of 120 fr. which they subscribed to add to the gift.

CHOLERA IN SPAIN.—According to late reports this epidemic is now committing terrible ravages in several southern districts of the Peninsula. For example, at Malaga 2267 deaths took place by that malady, from the 1st of May to the 29th of June last; of whom a large proportion were young persons. Accounts further state that, along the Mediterranean coast—at Motril, Adra, and Almeria, the disease has proved very prevalent; as likewise in Granada and Jaen, but especially at a place called Gualchos, where 178 deaths occurred during the first six days the malady broke out, while only two cases recovered. It has more recently attacked the inhabitants of Baylen, which is on the great highway to Madrid; where, however, public health is said to be at present satisfactory. In consequence of this outbreak of pestilential cholera in Andalusia, much terror prevails amongst the population.

NEW METHOD OF PRODUCING LOCAL ANÆSTHESIA.—Mr Richardson, the dentist, has sent us a communication, in which he says—"The subject of local anæsthesia has much excited the attention of the Profession lately. Dr Richardson, Mr Nunneley, and others, have devoted much time and research to it. Narcotics, congelation, inhalation of ether and chloroform, and, laatly, electricity, have all been tried, but, from some practical disadvantages in their application, and from the occurrence of dangerous and even fatal effects, none of these have met either the wants of the case or the general concurrence of the Dental Profession. In pursuing a series of experiments for effecting certain improvements in the 'Tooth Protector,' a notice of which apparatus was inserted in the 'Lancet' of 1858, I have devised a plan for causing local anæsthesia during the extraction of teeth without producing a corresponding effect on the system generally—viz., by immersing the affected part in chloroform, and including in the part immersed as much of the adjacent structures as may be required. It is obvious that a plan so simple must be universally applicable, and, should its reputation be maintained, prevent the escape of chloroform, and thus intensify its local effect. The cup is about half filled with cotton wool, which is then saturated with a sufficient quantity of chloroform, generally from ten to fifteen drops. The time within which local insensibility is produced varies from seven minutes to a quarter of an hour. It is true that the local anæsthesia is not in all cases equally complete; but even where pain occurs, the remedy will be found to moderate it to a point within which it becomes perfectly tolerable, and has lost the distressing agony of tooth extraction. It is important for the operator to remember, that as soon as insensibility of the part ensues, the cup should be removed, and extraction instantly performed. Of sixty cases on which the foregoing statements are based, only two occurred in which the remedy failed to mitigate the pain; whilst in ten cases the local insensibility during extraction was complete."—'Lancet.'

SUGGESTIONS FOR SANITARY INFORMATION.—The following important remarks are from a letter of Miss Nightingale to Lord Shaftesbury:—"It is stated to be a fact demonstrated by statistics, that in improved dwellings the mortality has fallen, in certain cases, from 25 and 24 to 14 per 1,000; and that in 'common lodging-houses,' which have been hotbeds of epidemics, such diseases have almost disappeared as heads of statistics, through the adoption of sanitary measures. It is also stated that in the British army large bodies of men living under certain improved sanitary conditions have presented a death-rate about one-third only of what the army has suffered in past years. Would not your Lordship consider it of great importance that the statistics of these and similar cases should be carefully collected and presented for comparison with the statistics of ordinary mortality? Again, it is stated that in our Colonial Schools for aborigines, we have in many instances exposed the children to the risk of scrofula and consumption while christianising and civilising them. Might not this be avoided by sanitary arrangements? . . . If facts already existing regarding the points I have mentioned above were carefully abstracted and made accessible to the public through the medium of the Congress, there cannot be a doubt of the great benefits which would accrue to science and humanity. And if, as it is the cost which frightens communities from executing the works necessary to carry out sanitary improvements, it could be shown that the cost of crime, disease, and excess of mortality is actually greater, it would remove one of the most legitimate objections in the minds of Governments and nations against such measures."

APPOINTMENTS FOR THE WEEK.

Wednesday, August 1.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, August 2.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2½ p.m.

LONDON HOME.—2 p.m.

Friday, August 3.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, August 4.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, August 6.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, August 7.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

J. R. (Medicus.)—The operation would not be attended with success.

A SUBSCRIBER is thanked; but the letter referred to is unworthy of notice.

Mr J. H. B.—Certainly.

CHIRON.—Syphilitic ulceration of the fauces is occasionally seen in large cities. It was described in this Journal a few weeks ago, in our "Spirit of the Periodicals," as an unnoticed form of disease. We have seen instances of it,—one of them in which the entire fauces were ulcerated away, nothing being left but the cartilaginous-looking walls of the excavation. After death the pharynx was so much contracted that a quill could scarcely be passed through it. It is a form of disease that should be further noticed.

SENEX.—1st. Yes.—2nd. You would be eligible.

MEDICUS.—Two guineas, payable after a written summons only.

A SUBSCRIBER (Portsmouth).—We cannot inform you.

DELTA.—The illegality must be first proved; so long as the diploma is supposed to have been obtained in compliance with the regulations, it would be held to be a qualification for the appointment.

Dr LONG is thanked for his note.

Mr S. W. SMITH'S note received: we will look into the matter.

G. B.—The circular has not reached us.

IOTA (Greenwich).—Renshaw is the publisher.

M.R.C.S. ENG.—The examination in preliminary learning would not, we presume, be strict; but competency would be required in all the more important professional branches.

A STUDENT.—You must pass the College of Surgeons first.

Mr BAKER.—Forwarded.

Mr GRANT.—We are unable to inform you.

Mr J. H. S.—1st. No.—2nd. No.—3rd. There is no examination required.

*** A CORRESPONDENT has forwarded to us the following advertisement in the 'Carnarvon Herald,' the object of which is to procure funds to testimonialise the skill of a country bone-setter. This man has, we understand, been recently appointed Medical Officer to a Slate Quarry, to the prejudice of a duly-qualified Practitioner. It is only merciful to hope that there may not be many broken bones on which to exhibit the ability of this "skilful operator." There is one class of animals to whom we should not throw pearls, and there is a class of Cambrians in whose behalf it would be sheer waste to throw away science.

"TESTIMONIAL TO MR RICHARD EVANS, BONE-SETTER, LLANLLYFNI.

"The Friends of the above skilful operator having frequently expressed their opinion that a Substantial Token of Respect is due to him for the numerous benefits they have received from him; they feel that the time is now arrived for closing a subscription so that a Testimonial may be presented which shall be worthy his acceptance, while it testifies to the superior advantage of skill when combined with that kindness of heart which distinguishes him. The following parties have kindly agreed to receive Subscriptions where lists are now lying, and which will be closed at the end of the present month.

Mr ROBERT HUGHES, Stag's head, Penygroes.
Mr OWEN JONES, Pencarmel, Cilgwyn.
Mr EVAN HUGHES, Blue Lion, Llanwnda.
Mr DAVID THOMAS, of the Victory, Carnarvon.
Mrs JONES, of the Harp Inn, Carnarvon.
Mr RICHARD JONES, Cwmyglo, Llanberis.

"A list of all Subscribers with their donations will be published shortly previous to the presentation.

"Carnarvon, July, 1860."

Mr RIX will see that his request has been complied with.

Dr TUCKER'S letter shall appear next week.

*** Will the Correspondent who sent us the information respecting the Skin Doctor who advertises under an *alias* favour us with further particulars?

FOREIGN DEGREES.

To the Editor of the Medical Circular.

SIR,—A short time since I addressed a note to you, requesting to know whether if then, or at any future time, a person were to leave England to study in any foreign College or School of Medicine, European or American, and if, after a regular course of study and examination, he obtained a Diploma from such College or School of Medicine, he could be registered in England as a legal Practitioner under the present Medical Act? You were kind enough to answer as follows: "Yes; such a Diploma would be registered in England."

This reply appeared to me very satisfactory; but on reading an account of the recent sittings of the General Council, I find that several gentlemen holding foreign Diplomas applied for permission to be registered, which application was refused, the Council replying that they had no power to register foreign Diplomas, except obtained after examination, and held by persons practising in England by virtue of such Diplomas previous to the passing of the present Medical Act. Now, Sir, this is a direct contradiction (I mean the latter part) to the answer you were kind enough to furnish to my question: I shall therefore feel greatly obliged if you will endeavour further to enlighten me on the subject, by informing me whether, in your view of the Act of 1858, a person holding a foreign Diploma, of whatever date, can claim to be registered in England, or whether his admission to be registered depends on the mere caprice of the Council? Will you also please to inform me whether, in case of the Council refusing to put his name on the Register, he can, without violating the law, call himself by the title given him by the College from whence he obtained his Diploma? Of course my questions refer wholely and entirely to such Diplomas as have been obtained after examination.

I will only say, Sir, in conclusion, that if the law of England, or any power sanctioned by the law, is so very narrow and exclusive as to refuse to register such Diplomas, our brethren abroad must inevitably contrast the selfishness of our Medical authorities with that broad and liberal spirit so characteristic of Englishmen generally, and the sooner the Medical Profession wipe out such a stain on their escutcheon the better.

Yours, &c.,

Sunderland, July 27, 1860. IGNORAMUS.

[The Medical Council have a discretionary—that is to say, an absolute—power to make any regulations they please. To entitle the holder of a foreign Degree to have it registered, it must have been obtained after examination, and before the passing of the Act. Our previous answer must have been given on this supposition. There is no law to prevent a foreign Graduate from styling himself "Doctor," or using the letters "M.D." That is our opinion, though our correspondent must be aware that attempts have been made to prove the contrary.—ED. MEDICAL CIRCULAR.]

Letters received from F. Ridd, W. Price, H. Seatle, J. Kenyon, R. F. Dill, R. P. Weston, A. S. Lawrence.

Paper and Envelopes.

A SAVING OF FULL 6s. IN THE POUND.

Cream Laid Note, 2s., 3s., and 4s. per ream.

Large Blue Wove ditto, 3s. 6d. and 4s. 6d. per ream.

SUPER THICK CREAM LAID ENVELOPES, 6d. per 100.

PRICE'S PATENT CANDLE COMPANY, LIMITED.

Millikin, late Bigg and Millikin,

Surgical Instrument Maker and Anatomical Machinist to Guy's and St Thomas's Hospital, No. 9 St Thomas's street, Southwark, S.E.

Briet's Celebrated Patent

GAZOGENE or AERATED WATERS APPARATUS, for the immediate production of SODA WATER, GINGER BEER, SPARKLING WINE, LEMONADE, &c.

SOLE AGENTS FOR GREAT BRITAIN,

MATHIEU AND FRIQUET,

5A Little James Street, Bedford Row, London, W.C.

This agency was first established by one of the Partners (Mr F. Mathieu), who kept it from 1851 to 1854, and is now a Branch of the Patentees' Paris Establishment. It is the only house in the United Kingdom supplied by the Patentees, and there is no other having the right to use the name of Agents for for them.

MATHIEU and FRIQUET are manufacturing the GENUINE LEMON SYRUP made from the actual FRUIT. When used with the Aërated Water from the Gazogene, it produces a pure and wholesome Sparkling Lemonade of the most exquisite and refined flavour.

Powders for Generating Gas in the Apparatus. Special and able Workmen from the Paris Manufactory are kept on the premises for the prompt and sound repairing of the Gazogenes, at low charges. No other repairers appointed by the Manufacturers.

WHOLESALE AND FOR EXPORTATION ONLY.

Price Lists sent on application on receipt of Business Card.

For Family Arms, send name

and county to the HERALDIC OFFICE. No charge for Search. Correct sketch and description, 2s. 6d.; in colour, 5s. Monumental brasses, seals, dies, and diploma plates, in Mediæval and modern styles. Lever-press and Crest dies, one guinea. Illustrated price-list per post.

ARMS, CRESTS, &c.—Gold Medal for engraving Crests on rings or seals, 8s.; on dies, 7s.; arms, crest, and motto, 25s; book-plate, 25s.

T. MORING, Engraver and Heraldic Artist, 44 High Holborn, London.

SOLID GOLD, 18-carat, Hall marked Sard, or Bloodstone RING, engraved with CREST, two guineas; seals, desk-seals, pencil-cases, &c. Send size of finger with orders for rings.

Struve's Seltzer, Fachingen,

VICHY, MARIENBAD, and other MINERAL WATERS.—ROYAL GERMAN SPA, BRIGHTON. Under her Majesty's especial patronage. The Pump-room and Promenade are now open for the 36th Season. The bottled waters are sold at the Pump-room, and by GEORGE WAUGH and Co, Pharmaceutical Chemists to the Queen, 177 Regent street, London, W., and by other respectable houses in London and the provincial towns, where a prospectus with the highest medical testimonials may be obtained gratis.—CAUTION: Owing to the use of Struve's bottles by other parties, please to observe that Struve's name is on the label and red-ink stamp affixed to every bottle of Struve's manufacture.

RUPTURES. BY ROYAL LETTERS PATENT.

White's Moc-main Lever

TRUSS is allowed by upwards of 200 Medical Gentlemen to be the most effective invention in the curative treatment of HERNIA. The use of a steel spring, so often hurtful in its effects, is here avoided: a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER, fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had, and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer,

JOHN WHITE, 228 Piccadilly, London.

Price of a Single Truss, 16s., 21s., 26s. 6d. and 31s. 6d.—Postage, 1s.

Price of a Double Truss, 31s. 6d., 42s. and 52s. 6d.—Postage, 1s. 8d.

Price of an Umbilical Truss, 42s., and 52s. 6d.

Postage, 1s. 10d.

Elastic Stockings for Varicose Veins,

and all cases of Weakness and Swelling of the Legs, Sprains, &c. They are porous, light in texture, and inexpensive, and are drawn on like an ordinary Stocking. Price 3s. 6d., 7s. 6d., 10s., and 16s. each. Postage, 6d.

JOHN WHITE, MANUFACTURER,

228 Piccadilly, London.

Notice—Behenna and Co.

ACCOUNTANTS, conduct all business entrusted to them, with secrecy, economy, and despatch. Accounts prepared in Bankruptcy and Insolvency. Arrangements made with Creditors. Medical Practitioners Supplied

with ASSISTANTS, gratis, by MAIR and SONS, 34 Bedford street, Strand, who also DISPOSE of PRACTICES on moderate terms.

Fresh Air. — "McKinnell's

PATENT VENTILATOR does that which is the great object in keeping buildings healthy. It rids them of the foul air, and provides for the free inlet of a fresh supply. It is simplicity itself—as, indeed, are most of the Mechanisms adapted to Natural Laws. It can be fitted with ease to carriages, ships, horses, coal-mines, schools, churches, &c. The system, too, is cheap."—'Medical Times,' July 7, p. 12.

JOHN McKINNELL, Patentee, 9 Gloucester terrace, Clarendon road, London, W. Descriptive Pamphlets sent on receipt of one stamp.

For Infants.—The British

FEEDING BOTTLE (registered) may be placed in any position without the food running out. The supply can be regulated by a stop-cock; being electro-plated, it may be instantaneously cleaned. Unlike wood, ivory, or bone, it is impervious to moisture, cannot crack or become sour; there is no possibility of the infant drawing air with the food.

By W. T. COOPER, Pharmaceutical Chemist, 26 Oxford street, London.

Price 7s. 6d., or free to any railway station, 8s. 6d.

Galvanic Institute,

52 Euston road.

These rooms have been opened under the superintendence of registered qualified Medical Men, for the legitimate application of Galvanism in the treatment of Nervous Diseases, Paralysis, Rheumatism, Asthma, Indigestion. It will also assist in affording the means of taking this branch of practice out of the hands of the unqualified. Hours of attendance twelve to five (Sundays excepted).

Ordinary Medical Attendant, Mr J. Smellie, Surgeon

CLINICAL LECTURES.

ON THE DIFFICULTIES THAT ATTEND THE DIAGNOSIS OF THE NERVOUS AFFECTIONS

KNOWN AS INTERMITTENT TETANUS, TETANILLE, IDIOPATHIC MUSCULAR SPASMS, ETC.

DELIVERED AT THE HÔTEL-DIEU,
By M. TROUSSEAU.

(Continued from page 69.)

In some patients it is only necessary to make pressure above the clavicle, on some part of the nerves of the brachial plexus, in order to bring on spasm. It is possible, then, to recognize this disease whenever, by compressing the origin of the nerves that go to any member, you can at pleasure bring on contraction. The importance of this diagnostic means is at once apparent.

This kind of contraction comes on suddenly, and rapidly attains a degree of great intensity, reaches its *maximum*, and then begins to decline. The duration of the disease in its explicit period varies from ten days to two or three months; but in this last case it is in a latent state; that is, it can at any time be produced by the influence of pressure.

Among the causes which I have to mention, I should say that obstinate diarrhœa seems to predispose to this affection: hence, during the epidemic of 1854, a great number of cases might be seen. This fact at first quite escaped my notice; but M. Lasègue and M. Aran have very strongly called the attention of Practitioners to this precursory circumstance. A clinical confirmation of this fact you have now under your eyes; since the woman in the Salle St Bernard, as well as several other patients whom you have seen during the last twelve months, had all been suffering, before their admission into the Hôtel Dieu, with intestinal flux.

The young man who was taken to the Prefecture of Police in the state I have described to you had not experienced any previous diarrhœa, but he had been exposed to cold and wet; and I have already noted atmospheric impressions as one of its frequent causes. Typhus fever, cholera, cholerine, and the action of external agents, thus far are as nothing; but the etiological circumstance that exerts the greatest activity, beyond contradiction, is nursing. We have here twelve beds appropriated for wet-nurses; among these we meet with a far greater number of cases than among all who occupy the other fifty beds. At the Neckar Hospital, where, in my *service*, there are thirty-six beds for women who suckle, and forty for adult women who do not, I have observed forty cases of rheumatismal contraction in the former, and only one in the latter. I have reason, therefore, for saying that lactation is a circumstance of great importance. But why is it so? Oh! do not ask me, for I know nothing of the reason, absolutely nothing.

The disease, even when left to itself, seems destitute of everything like gravity. The organic life seems to derive no taint from it, and to be in no measure disturbed, with exception of the febrile movement. No fear need, therefore, be entertained regarding the issue. Yet, in exceptional cases, and in its grave form, the spasm is seen with such a degree of intensity that you will be under the necessity of meeting it with very active means. Four or five years ago I had such a case for four months, and the patient, a woman, did not recover without the use of the most energetic treatment.

Were you not aware of the possible occurrence of such facts as I have just related, you might easily suffer yourselves to be imposed upon by the apparent severity of these symptoms, and mistake them for symptoms dependent upon some very serious pathological state; but it is easy to see, from the fleeting and fugacious nature of the phenomena, that they cannot be dependent upon any very profound or permanent organic lesion. For more than twenty years, during which time my attention has been called to this disease, I believe I have not seen a single case where death followed; yet I am told that the young man who was shown to M. Lasègue as epileptic has come to a sad end at the Hôtel-Dieu, under M. Rostan. Six weeks after leaving my wards, he was seized, it seems, with renewed spasms, cough, dyspnœa, sweats, and, in the last days of his life, feebleness of the limbs, which was well marked, and considerable orthopnœa. The autopsy showed the existence of ramollissement of the superior portion of the spinal marrow, and the usual lesions seen in pulmonary phthisis. In this case, it is plain that the tubercules contributed not a little to the fatal result.

What is the nature of the disease? That it belongs to the neuroses, no one doubts; neither can any one doubt that it should be ranked with epilepsy, hysteria, eclampsia, and catalepsy. The organic lesions evidently should be slight and quite superficial, since motility is not suspended, excepting while the contraction lasts; nor is the perfect integrity of intellect impaired, for such patients are gay and converse as usual, and all the functions are perfectly executed, while they have, in the intervals between the attacks, all the appearances of good health. There are not, therefore, I repeat, serious lesions of the brain or spinal marrow. My opinion is that this neurosis is rheumatic. Its extremely fleeting nature, and the rapidity of the attack, and the superficial character of the symptoms, all induce me to consider it as such. Besides, blood taken from a vein is coated as in articular rheumatism, and in several cases, as remarked by M. Delpech, rheumatism and spasms are found to alternate. When I first began to notice cases of contraction, I was seized with alarm, and really believed that such were grave affections of the brain or spinal marrow.

Bleeding from the arm, and cupping along the spine, have, I must say, been of great service; and I do not hesitate to declare that detraction of blood is in such case a means of incontestable power whenever there is no counter-indication in the general state. I shall not be much doubted when I speak of the efficacy of blood-letting, for you know that I do not abuse the lancet. I must, then, be well convinced that opening a vein is a good therapeutic means, or you should not hear me recommend it.

The notion I formed of intermittence led me, in this affection, to prescribe quinine, which has done me good service, though under its use patients do not recover so surely as with bleeding from the arm. Four years ago I had a patient, a woman, who was suckling twins, and who was seized with rheumatismal contraction after a persistent diarrhœa. After treating the intestinal flux, the nervous affection was attacked with sulphate of quinine. As you may suppose, loss of blood in such case is not to be thought of. Inhaling chloroform, during the attack, is occasionally of some benefit; and, thanks to this anæsthesic agent, though the rigidity disappears only to return a little after, some amelioration is always the result. Opium and belladonna, in moderate doses, are medicines the good effects of which I must also mention, though they do not in the least diminish the value of venesection and sulphate of quinine, which maintain their right to the best place.

I would, in conclusion, recommend you all to follow with minute attention the various phases through which our patient in the Salle St Bernard will pass. No doubt she will get well, and that, too, ere long; do not, then, lose sight of her case, for I am convinced you will be able to derive from it more than one useful lesson.

ON THE TREATMENT OF GONORRHŒA WITHOUT SPECIFICS.

By J. L. MILTON.

(Continued from p. 35.)

Great Natural or Induced Weakness.—By this is meant, not great physical exhaustion, but that weak, irritable state of the system under which the stomach loathes the mildest and smallest doses of medicines of any class—a state of matters sometimes induced by inordinate quantities of copaiba. The patient is gloomy and weary; sometimes prostrated by sick headaches, at other times scarcely able to rise from mere lassitude. A cold confines him for a week; his bowels are costive—his tongue coated—his enjoyment of all comforts is lost or weakened. Active purgatives, in the form of aloes, coloeynth, and blue pill—effervescent mixtures with syrup of orange peel—mild sedatives, and, as soon as possible, quinine in grain doses three times a day, generally prove quite effectual. Injections are indispensable; but as many of these patients suffer from excessive sensibility of the urethra, they may be made very weak at the outset, and not employed more than once a day till the bowels have been repeatedly purged, when they can be used as in other cases. A moderately tonic diet, with a fair allowance of meat—a little spirit or wine daily—total abstinence from porter, ale, stews, hashes, pastry, &c., will be found of great benefit.

As an instance of this complication in its most severe form, I may quote here the history of a case in which it appeared to have been chiefly induced by large doses of copaiba. The patient was a member of the medical profession, who placed himself under my care after having made a most unsatisfactory attempt to treat his own case.

I found him low, weak, and dejected; he was suffering under enlarged prostate, with a painful bearing-down as if the rectum were coming out, so that when walking he constantly felt an urgent desire to keep his hand pressed upon the anus. There was a moderate amount of discharge, with no great pain in making water or during erections. The tongue was brown, furred, tremulous, and indented by the teeth—the breath was foul—his face looked coarse and dusky—he said he had lost all his colour, along with his appetite and strength. Great part of his sufferings he attributed to the amount of copaiba he had taken; and as, according to his own estimate, he had for some time past managed to get down five oz. a week, the supposition was very feasible. The use of these enormous doses was always followed by nausea and loose stools. To complicate the case still further, it appeared very doubtful, from the patient's description, whether there was not some stricture to be apprehended, as six years previously he had suffered under gonorrhœa, which, after having been duly treated with copaiba, slowly changed to a gleet, which every now and then reappeared; so often, indeed, that I doubted if it had ever been cured. Latterly also there had been a good deal of dribbling after making water, and, the patient thought, some slight narrowing of the stream.

"All this," he said, "I could endure, and hope to see cured. There is some visible cause for these sufferings, but I cannot understand why I have this dreadful irritability of temper and gloominess always hanging about me. I feel no pleasure in anything I do, and I am quite certain many of my patients have remarked my inattention."

On examination by the rectum, the prostate was found greatly enlarged, and a blister was or-

dered to be applied. A bougie was also passed, and a most irritable state of the urethra discovered: no stricture, however, was encountered. Within forty-eight hours after this operation, the right testicle swelled in a most extraordinary way. The patient for several days could not allow me to touch it, and the attack was accompanied by such prostration that he was obliged to confine himself to his room. Morphia in large quantities was ordered, and relieved him so rapidly, that he said "he could hardly describe the comfort this dreamy, quiet state inspired, compared with his first night's suffering. Hot water to the scrotum, so as almost to excoriate it—a well-fitted suspensory bandage—a brisk aperient, and a diet from which all cold, accescent, heavy articles of food were rigidly excluded, soon relieved all the most severe symptoms.

At the end of a week I examined the testicle; and though this was the worst case of orchitis I ever saw, I was not prepared to find such evidences of active disease. The epididymus was greatly enlarged and of almost cartilaginous hardness, as was also great part of the testicle; and though all pain was gone, yet the patient still shrank instinctively from the slightest touch. I now asked him if he had ever strapped the testicle for orchitis; to which he candidly admitted that he had. Then I said, "How would you like to have your own testicle subjected to the process?" To which he simply and touchingly answered, "Not at all."

The discharge was now treated with mild injections of nitrate of silver, followed by the use of gum elastic bougies, every second day. Two blisters were applied to the perinæum, and two to the penis. Iodide of potass was given in doses of ten grains twice a day; calomel and black draught were given twice a week. A full meat diet was ordered, and a bottle of claret daily.

The discharge soon ceased entirely. The urethra became so healthy, that the bougie could be passed with scarcely any discomfort. After the first three weeks the prostate gave him no further annoyance; and finally such a steady and rapid subsidence of the hardening of the testicle ensued, that when he paid me his last visit, about four months from the beginning, little more than a slight thickening remained to mark the seat of disease. His tongue became clear, moist, and firm—his appetite returned, and he soon gained flesh and strength. From having been unable to walk a mile without fatigue, he was now almost as well as he ever had been, and in better health than he had enjoyed for years. He has never strapped a testicle from that day.

3. *Morbid Sensibility of the Urethra.*—In excessive tenderness of the urethra, it is sometimes necessary to wait a day or two, that the action of the potass may be set up, and to give a sedative every night before beginning with injections. The first two or three of these may consist of warm water; the next, of weak solution of nitrate of silver, beginning, in some persons, as low as one tenth of a grain to an ounce: after this no further precaution is necessary. Where this extreme sensibility seems dependant upon rheumatism or gout, a grain of the extract of colchicum every night is often very serviceable.

Strong Tendency to Stricture—that is, where the canal begins to contract within the first week or fortnight after the appearance of the gonorrhœa—though not very uncommon when this disorder is neglected, has only occurred in my experience three times in cases treated properly with potass and injections. In two of them it yielded quickly enough to the solid nitrate applied by means of a sheath and stilette (*a*)—an instrument which has also often stood me in good stead in those cases where isolated parts of the urethra remain tender and throw off shreds after the removal of old gleets. In the third case, the patient, quite a lad, was suddenly despatched on business, which enabled him to indulge in the pleasures of the table to any extent he liked. Not having enjoyed such a privilege before, he made the best use of it now—lived on game, salmon, champagne, punch, &c.—and returned to London with the urethra closely strictured for about two inches; a state of matters which required about eight months to set right again.

(*a*) For a full description of this instrument and the best method of using it, see 'Treatment of Spermatorrhœa,' by the Author, 5th edition, page 38.

In five cases this affection could be traced to the use of chloride of zinc injections; and though I believe these may, under proper care and when made to follow the exhibition of potass, be used with impunity, my experience of their employment without such precaution is, that they are always painful, and at times dangerous.

(To be continued.)

FRACTURE OF THE FORE-ARM—FATTY TUMOUR OF THE VAGINA—HYDATID GROWTHS SIMULATING PREGNANCY.

By THOMAS FALCON, Esq., Surgeon.

Three years ago I was requested to visit J. Wood, a stone-mason, who had received a severe injury to the fore-arm and elbow-joint, in consequence of a large stone post (which he and another man were removing to an excavation prepared to receive it) falling upon and crushing the limb. The fore-arm and joint when I arrived were so swollen, contused, and ecchymosed, that it was utterly impossible for any one to ascertain the exact amount of injury received. That there was a fracture of both bones of the fore-arm at the upper third, was evident from the distinct crepitus felt on each side of the limb. After the inflammation had been subdued and the tumefaction had subsided by the repeated application of leeches, fomentations, and general constitutional treatment, then for the first time could I discover that not only had there been a fracture of both bones of the fore-arm, but that the upper portion of the fractured radius had been dislocated upon and thrown into the hollow above the external condyle. I explained to the man that it would be utterly impossible to reduce the outer bone of the fore-arm, and that though for a considerable time the motion of the limb might be imperfect, yet that ultimately he would be likely so far to improve that he would be able to follow his usual employment. I had recourse to passive flexion and extension of the joint after the fractured bones had become consolidated, but could only bend the fore-arm to about a right angle with the humerus. I then told him he might consult some other surgeon, if he thought proper. Mr Teale, of Leeds, saw the case, and advised the passive motion of the joint to be continued. A quack was afterwards consulted, who gave it as his opinion that the couplings of the joint were out, that I ought to have thrust them in, and that the patient would easily obtain heavy damages from a jury in compensation to the man for the bad management of the case. This opinion was very modestly given by a man who some years ago employed five men to reduce a dislocation of the hip in a man seventy years of age—the case being one of fracture of the upper third of the femur (unless he had fractured the bone by his manipulations), with the edge of the fractured bone immediately beneath the skin. The hideous appearance of the limb in consequence of the diffuse inflammation which followed, and the agony which the patient endured, may be as easily imagined as described. Is it possible to reduce a dislocated radius with fracture below? or would such an operation as cutting down upon the radius, and removing that portion of the bone above the insertion of the biceps, be advisable in such a case? I thought that such an operation would be utterly unjustifiable, although I should suppose it might be performed with care without injury to the brachial artery. The result proves how admirably Nature adapts herself to altered circumstances, for he can now use the injured arm in his business as a stone-mason as well as the other. This man threatened me with an action at law for malpractice.

2.—Fatty Tumour of the Vagina separated from its Attachment by the Head of the Child, and expelled during Labour.

Three months ago I was summoned early in the morning to attend Mrs Hardy, of Pudsey, in her confinement. The child was born when I arrived, and the placenta, being in the vagina, was easily removed. Syncope, however, came on to an alarming extent, which I was unable to account for, as there was no hæmorrhage and the uterus had contracted. Mr Wade, of Stanningley, had been in attendance on the woman previous to her confinement, and had found on examination a tumour depending from the anterior part of the vagina. He was summoned on the morning of her confinement, but was unable to attend. He, however, arrived previous to my departure, and whilst I was administering stimulants to the patient. On hearing the previous history of the case, the obvious inference of both of us was that some laceration had occurred. The tumour was found on the bed after she had recovered from the syncope. It was about the size of a large potato, and consisted wholly of condensed fatty substance. The case went on favourably, no bad symptom occurring after the syncope had subsided. She made water freely soon after: I therefore did not make any further examination *per vaginam*. Are fatty tumours in the vagina common? Would any surgical interference during the existence of pregnancy be considered correct practice in such a case by the *savans* in the Obstetrical department? That, I should suppose, would depend upon the nature and extent of their attachments, and the amount of obstruction and laceration which might be anticipated.

3.—Hydatid Growths simulating Pregnancy.

I was summoned in a great hurry at midnight on the 22nd of June last to see Mrs Richardson, of Pudsey. The messenger (her husband) informed me that she was rapidly sinking from flooding, and was far advanced in pregnancy. I found that a large quantity of coagulated blood had been passed: the system had experienced a great shock. I examined *per vaginam*, and found what I thought to be a placental presentation, the fundus uteri on a level with, or rather above, the umbilicus; and I saw no reason to call in question the impression of the patient, that she was in the seventh or eighth month of pregnancy. I succeeded in restraining the hæmorrhage by cold applications to the vulva, &c., and exhibited the mineral acids more as a placebo than with any idea of deriving much benefit from their use. I had resolved to employ the tampon soaked in a saturated solution of tannin, should the hæmorrhage return. Other attacks of hæmorrhage had occurred previously to my being called in; and she had been attended in the first place by Mr Machill, and afterwards by Mr Field, surgeons. I gave it as my opinion to the husband that she was in a most dangerous state, and that it would be necessary to induce premature labour should she so far recover from the shock as to render it justifiable and necessary by reason of a recurrence of the hæmorrhage. I was summoned at 5 a.m. on July 6th, and found that uterine contraction had commenced, and the vagina distended, apparently by the placenta. This substance was soon expelled, and quickly followed by other dense masses of coagula. I saw by the expression of her countenance that no time was to be lost, and was about to introduce my arm, in order to turn if practicable, when I found, on applying my hand over the abdomen, that the uterus was rapidly emptying itself, and in a very short time the whole of its contents was expelled. She fell into a death-like swoon, vomiting and tossing about from one side of the bed to the other. I succeeded in inducing permanent contraction of the uterus by grasping that organ over a napkin soaked in cold water, and she gradually rallied after the administration of brandy and the application of heat to the extremities. What would have been the proper practice had a correct diagnosis been made at an earlier period? Would the exhibition of the ergot of rye have stimulated the uterus sufficiently to produce a detachment and complete expulsion of this immense mass of hydatid, embedded in dense fibrinous deposit, as I believe the unaided efforts of nature had succeeded in effecting in this case? or would introducing the finger or hand, and scooping out the uterine contents, have been preferable? The patient was in such a weak and prostate state when I was first called in, that I am now perfectly satisfied with the course I pursued in having left the case to nature, enjoining the most perfect quietude, supporting her strength by nutritious broths, and employing the cold applications which succeeded in restraining the hæmorrhage. It was the opinion of the females in attendance that the whole of the mass expelled when the uterus finally emptied itself could not have amounted to less than a gallon. The hydatids varied in size from that of a currant to a grape. Writers state that the size of the belly does not correspond to

the supposed period of pregnancy. In this case the woman believed herself to be in the seventh or eighth month of pregnancy, and the uterus had ascended to the umbilicus. It was this coincidence which deceived me, and led me without further reflection on the case to the belief that she was pregnant. The same view of the case, I understand, had been taken by the two surgeons previously in attendance. There was a profuse and offensive watery discharge, which continued from the 22nd of June, when I was first called in, to the 6th of July. It might be objected to this case, that it would be almost impossible to mistake a clot of blood at the *os uteri* for a placenta. But some of these masses, having probably remained for months in the uterus, had become so firm and solidified as to render it very difficult indeed to distinguish them from an after-birth. Medical writers assert that these hydatids are formed, in the great majority of cases, in consequence of the destruction of an ovum. There was a blighted ovum in this instance; but I remember seeing them connected in one case to the placenta of a well-developed and healthy child. The patient is now (July 30th) gradually recovering her strength, and is able to walk about the room.

Fulneck, near Leeds.

THE SPIRIT OF THE PERIODICALS.

We extract the following article on *Perforating Tumours of the Dura Mater*, by Dr C. T. Cooke, from the 'London Medical Review:'

"Perforation of the cranial walls may be due to a variety of causes. Of these, if we exclude mechanical injuries, the most frequent are syphilitic and carcinomatous disease of the pericranium; scrofulous and carcinomatous degeneration of the diploë; and the pressure of the intracranial tumours.

"It seems probable that tumours of every description, and growing from whatever part of the brain or its membranes, are capable of effecting a perforation of the bony wall. Thus, an hydatid cyst, growing beneath and elevating the dura mater, has been known to erode the inner table of the skull; and the same fact has been often observed in the case of hypertrophied Pacchionian bodies. But by far the most frequent seat of perforating intracranial tumours is the external surface of the dura mater. Tumours situated in this locality are undoubtedly for the most part cancerous, belonging generally to the medullary, rarely to the epithelial, variety of the disease. But there is a form of tumour to be met with here, the characters of which (although it is unhesitatingly classed by Rokitansky among medullary cancers) render its nature still a matter of controversy. It is that to which Lebert has assigned the title of 'fibro-plastic.'

"Whether these growths are or are not cancerous, is a question which may safely be left on one side until pathologists shall have arrived at some agreement as to the definition of cancer. But, however this may be eventually determined, it seems certain that they possess marks sufficiently characteristic to entitle them to be regarded as a natural group distinct both from epithelial or from medullary cancer. These marks are, that they contain no milky juice; that they do not soften from the centre; that they occur in one part only of the same individual; and that they possess none of the histological elements of epithelium.

"The above characters apply to all fibro-plastic growths, wherever situated. It will be seen farther on, that, when growing from the external surface of the dura mater, they are equally distinguished from ordinary cancer by the mode in which they perforate the bones of the skull.

"Unfortunately we possess very few authentic and well-reported cases of this disease. It is, indeed, probable that the 'sarcomatous' tumour which perforated the left parietal bone, and to which the name 'Fungus of the dura mater' was first assigned by Louis, was a fibro-plastic growth; and a similar probability attaches to a few more of the earlier recorded cases. But, on the whole, the older literature of the subject affords embarrassment rather than assistance. For, from the year 1774 (when attention was first drawn to it by Louis, the secretary of the Royal Academy of Surgery in Paris), to within quite recent times, all diseases capable of producing perforation of the skull seem to have been indiscriminately heaped together under the appellation of Fungus of the dura mater.

"Under this heading, for instance, may be found a case of caries after fracture; of congenital encephalocele; of fatty subcutaneous tumour; and three cases of cancer of the diploë. And, even when there is reason to suppose that the author has been correct in regarding the dura mater as the primary seat of the disease, it is in most instances a hopeless task to endeavour to determine, with any approximation to certainty, the nature of the tumour which grew upon it.

"I gladly avail myself, therefore, of the opportunity (for which I am indebted to my friend Mr De Morgan) of placing on record a recent and highly-interesting case of this obscure disease. Two meagre and unsatisfactory cases by H. Cloquet, and a valuable one by Dr N. Friedrich, of Würzburg, constitute the whole remaining stock of authentic cases available for purposes of comparison.

"Alfred Chapman, aged fifteen, was admitted into the Middlesex Hospital on the 8th November, 1859, under the care of Mr De Morgan, suffering from total blindness and inability to walk.

"He complains of severe frontal headache. Both pupils are widely dilated, and quite insensible to light. He has also strabismus, and an incessant twitching of both eyeballs and eyelids. His tongue and uvula are drawn to the left side; the angle of the mouth slightly to the right. On the left frontal eminence is a hard swelling, about as large as a small bean, flattened, immovable, and apparently attached to the bone. It is a little painful on pressure, but not otherwise. Neither the patient nor his friends were, at the time of his admission, aware of its existence.

"His inability to walk seems to depend merely upon a want of the power of co-ordinating the movements of muscles, and upon no loss of muscular power.

"He can use his hands, but he generally allows them to hang listlessly by his sides, flexing the thumb on the palm, and the fingers over it, in a very peculiar manner.

"There is no loss of common sensation anywhere.

"His memory seems pretty good; but he answers questions very slowly, and not in a lucid manner.

"The left fibula is enlarged and curved slightly outwards and backwards at the lower third, where the integuments are thickened. This enlargement is at times painful.

"*History.*—His father is living and in good health. His mother died some years since insane. Three sisters died in infancy; two of 'atrophy,' the other of fever. There is no history of cancer nor of syphilis in the family.

"He is by occupation a farm-labourer in Northamptonshire, and enjoyed good health up to the date of this illness, except that, for about six months, he had suffered from frequent 'weakness of sight,' which compelled him to discontinue work for the time.

"On the morning of September 17, 1859, a very warm day, he went, as usual, to his work in the fields. He was soon seized with violent headache, nausea, and heavy dragging pain in the legs. He went home, and was there attacked with vomiting, which continued incessantly during the night, and was followed the next day by diarrhœa and 'failure of sight.' Two days later, when first seen by a medical man, he seems to have been in a very weak state: the diarrhœa was persistent; loss of vision was total; and the pupils had become dilated and fixed. During the next week or ten days he suffered from fever and delirium; he then began slowly to improve. No change, however, took place in his vision, except that he now occasionally fancied that he saw flashes of light, or even a candle, in a perfectly dark room. (Photopsia.)

"Between two or three weeks since he began gradually to lose the power of locomotion, not apparently from muscular weakness, but from want of directing power; and at the same time complained of pain in his knees. Three days before admission he had had another attack of fever, headache, and vomiting; but these symptoms, with the exception of the headache, had passed away.

"He was placed on ordinary diet, and a mild mercurial treatment was adopted, consisting at first of hydr. c. cretâ, and subsequently of the liq. hydr. bichlor. in small doses, and in the application of strong mercurial ointment to the frontal tumour.

"The headache speedily disappeared; but no other change occurred until—

"Nov. 23, when he had a convulsive attack of a peculiar character. His limbs were forcibly extended, the twitching of his eyeballs increased greatly in rapidity, and he rolled restlessly about in his bed, crying in a strange childish manner, and muttering a few unintelligible words. There was no dyspnœa, nor did he foam, or bite his tongue. His pulse rose during the fit (which lasted five minutes) to 100—104.

"He is said to have had a similar fit before admission. These fits continue to recur through the month of December; but after the 11th of that month were accompanied by dyspnœa and lividity. During the same period other important changes were noticed.

"On Dec. 11th, the distortion of the face, which had hitherto been directed towards the right, was now suddenly changed to the opposite side; while that of the tongue and uvula remained unaltered.

"The frontal tumour, also, was observed to increase very much in size from the 4th December. On the 11th, it measured two-thirds of an inch in its longest vertical diameter.

"On the 17th, it was not only found to be much increased in size, but the bone felt as though split asunder in the centre, so as to admit of the protrusion of a soft substance, which communicated an impulse to the hand when the patient coughed.

"On the next day (18th), it is noted—'Had three fits, during which the tumour became very much swollen; but no pulsation can be felt in it. Headache very severe.'

"Omitto Medicamenta.

"Dec. 23rd.—Pulsation can now be readily detected in the soft centre of the tumour, which projects through the bone.

"From this period the tumour continued to increase in size, and was accompanied by increased facial paralysis of the right side until January 12th, 1860, when it was noticed that the corner of the mouth was again drawn to the right, and this was soon followed by paralysis of the left orbicularis oculi.

"This fresh attack of paralysis continued until Jan. 23rd, when it began suddenly to abate; and by February 5th, the left eyelids could be completely closed.

"He had now had no fit for twenty-nine days; he ate and slept well. In this comparatively favourable condition, and with entire immunity from fits, he continued for nearly ten weeks. On March 17th, however, the fits recommenced, and were accompanied by headache and sickness, and (in April) by an attack of diarrhœa.

"On the 4th April, a bad attack was induced by excitement (a case of severe accident having been suddenly brought into the ward). On this occasion there was marked dyspnœa and increased squinting, and twitching of the eyes; but no foaming at the mouth.

"During this month his health and strength seem to have undergone rapid deterioration. The fits again became frequent, and the note of April 22nd runs as follows:

"'April 22nd.—Another fit to-day. Severe frontal headache. Skin cool; pulse 92, of moderate power. Tongue dry and brown. Appetite bad. Tumour, if anything, larger. Pupils still dilated. 1.15 p.m. was suddenly called to him, as he has been seized with dyspnœa. His face is livid, and covered with drops of sweat. Respiration has almost ceased. Pulse too rapid to count. The pupils are contracted, especially the left, which is about the size of a pinhole. He is quite insensible.'

"In the course of a few minutes he died. The post-mortem examination was made twenty-four hours after death.

"The calvaria and brain were removed together; the former being so separated as to include the orbital plates of the frontal bone. On the brain being raised from the base of the skull, both lateral ventricles and the third ventrical were seen to be immensely distended, so as to

project upon and compress the structures at the base of the brain. The distension was so great, that a very slight accidental puncture made at the base of the anterior lobe of the left hemisphere penetrated the lateral ventricle, and allowed the escape of a large quantity of pellucid serum.

"The dura mater was found to be uniformly, but slightly, adherent to the calvaria over the frontal and both parietal bones, and the greater wings of both sphenoids. On its being gently detached, the inner surface of these bones presented the very peculiar appearances of that form of atrophy to which the name of Usura or Detritus Ossium has been applied. These are essentially three, viz. :—

"1. In patches, of very variable extent, the inner table of the bone was merely roughened and eroded. The diploë was entire.

"2. In other similar patches the inner portion of the bone had been entirely removed, leaving deep excavations often large enough to contain an almond. The external layer of bone was, in many of these instances, only 1‴—2‴ thick. But these excavations had not been effected merely by the destruction of the inner table of bone, and the exposure of the diploë. On the contrary, as the process of absorption extended outwards, the diploë seemed to have converted itself, by a deposition of new bone, into a hard eburnated tissue, presenting no trace of its original cancellated structure.

"3. In other spots, solitary pits or cavities had been excavated in the bone, varying in size from that of a pin's head to that of a split-pea. Of these fifteen were counted, of which five had perforated both tables of the skull, and were covered only by pericranium. The great majority of these pits were situated in the upper portion of the left parietal bone.

"The largest of these perforations was that which had been recognised during life, on the frontal bone. The external aperture, covered by periœranium only, measured 1.062" dm. ; the internal aperture only .75" dm. The latter was surrounded by a ring of firm hard white bone, in which no trace of diploë was visible. The former was also surrounded by a smooth elevated ridge of new bone, .125" in height.

"As in the case of the wider and more shallow excavations noticed above, the sides of these pits consisted invariably of a layer of hard new bone.

"*The Dura Mater.*—The condition of the dura mater corresponded strictly with that of the inner surface of the skull.

"1. On surfaces answering to the patches of eroded bone, the dura mater (generally injected) was covered externally with innumerable minute growths, scarcely larger than a grain of sand, but communicating a sensation of roughness to the finger. They were very readily detached from the membrane on which they grew. This condition appeared to represent the earliest stage of the disease.

"2. The large shallow excavations were also lined with dura mater, bearing numerous flat, roundish growths reaching the size of a split pea.

"3. The solitary pits and spots of perforation were filled with similar growths, of very variable size. Some of these scarcely exceeding a pin's head in thickness had yet completely perforated the skull.

"Where the perforation was only partial, it was easy to withdraw these tumours from their cavities, by gently detaching the dura mater from the bone. They evidently, therefore, had no intimate organic connection with the latter.

"In the case of the older tumours, which had nearly or quite perforated the bone, the dura mater had undergone a very remarkable alteration, which has not, so far as I know, been hitherto noticed. After forming a very firm adhesion around the internal aperture, it had passed up with the tumour into the cavity. Here it seemed to have suffered partial absorption, and losing its membranous character, to have been converted into a series of fibrous bands, radiating from the border of the internal to that of the external aperture, where they appeared to lose themselves in the pericranium. This peculiar condition was very well marked in the frontal tumour.

"The arachnoidal surface of the dura mater was considerably injected in several places, but otherwise healthy, except upon the upper surface of the left hemisphere. Here a very considerable number of growths (none exceeding a split pea in size) connected the dura mater with the subjacent arachnoid, and were in some instances inseparable from the grey substance of the hemisphere.

"Both lateral ventricles and the third ventricles were enormously dilated ; the lateral ventricles being each capable of containing half-a-pint of fluid. The brain presented no other morbid appearance.

"The chiasma and the nerves at the base of the brain had undergone no apparent structural change.

"*Structure of the Tumours.*—For the purpose of examination, portions were taken from tumours of all sizes. Their general characters were, however, identical.

"1. They were soft and of an olive brown colour. No milky juice escaped on section.

"2. They were extremely vascular. Some of the smallest appeared to be merely loops of gigantic capillaries, supported by a slight fabric of areolar tissue.

"3. The histological elements consisted of (*a*) Recent areolar tissue, with elongated spindle-shaped cells in various degrees of development. (*b*) A small proportion of round cells, containing each one minute nucleus. In the growths as large as a split pea, these cells had already undergone fatty degeneration, and had the appearance of compound granulation corpuscles.

"The enlarged fibula was very vascular, and in its upper two-thirds was thickened by a deposit of new bone to about twice the diameter of the lower third. The medullary canal was normal. No foreign growth could be discovered. All the other organs of the body were remarkably healthy."

'The British American Journal' contains the following article on *Impromptu Tracheotomy*, by Dr HORACE NELSON, which is worthy of remembrance by General Practitioners.

"How many persons have perished, perhaps in an instant, and in the midst of a hearty laugh, the recital of an amusing anecdote, or the utterance of a funny joke, from the interception at the glottis of a piece of meat, a crumb of bread, a morsel of cheese, or a bit of potatoe, without a suspicion, on the part of those around, of the real nature of the case!" — 'Foreign Bodies in the Air Passages,' p. 43.

In exemplification of the above remarks of Prof. Gross, the recital of the following case may not prove uninteresting to the readers of the 'British American Journal,' at the same time it shows what could or should be done in cases of great emergencies. On the 19th January, 1857, while coming from the Post Office, in Plattsburgh, I was stopped at the door of a grocery-tavern, and called in to meet Dr Hall, to see a man supposed to be dying. Stepping in, I found an old soldier, of the Peninsular War, named Davis, and for many years an inmate of the County Poor House, evidently expiring—his face was blue, suffused and bedewed with cold sweat ; the eyes staring wide, fixed and glassy ; the mouth opened ; pulse just flickering at the wrist : in one word, the cold hand of death was pressing upon him with fearful rapidity and certainty. In a few seconds I ascertained the following particulars :—That morning he had deserted—as was his wont frequently to do—from the Poor House, and came to the village for a glass of grog, obtained upon the proceeds of begging from a few who pitied the lone and decrepit soldier ; and on this occasion, having been more than usually fortunate in his foraging expedition, he resolved to indulge in something of a dinner ; after taking a 'hasty plate of soup,' he went to work in demolishing a piece of shank beef, and with hunger and the loss of his teeth, he was disposed to do justice to his coarse food, when, after taking the first mouthful—and not a small one—at that he was noticed by the landlady to gasp, turn blue in the face, and drop from the chair upon the floor. Dr. Hall was immediately sent for, when, seeing the danger and urgency of the case, he requested my assistance. Presuming that the suffocation resulted from the impaction of a piece of bread or meat in some portion of the larynx or trachea, I opened the man's mouth as wide as possible, but neither with the eye nor finger could I detect anything ; the all-certain and prompt death of the poor fellow staring me in the face, left me no time to speculate upon the course of treatment to be adopted, and still less to run to my surgery, a few squares off, to procure the necessary instruments ; therefore, I at once proposed to the Doctor, in which he readily acquiesced, that desperate as the case was, there remained but one chance, and that was to make an opening in the trachea. Seating the man on a chair near the window, the head being thrown back as far as possible, with a thumb-lancet I cut through the integuments, cellular tissue and fascia, from opposite the cricothyroid space, in the median line, over the cricoid cartilage down to the two upper rings of the trachea ; separating, by scratching with the finger-nail and handle of the lancet, the sterno-thyroid and hyoid muscles from their congeners, the cricoid cartilage and rings of the trachea were exposed to view, to divide which with my lancet was quite out of the question ; they were so old and ossified, that I had to resort to a good sharp penknife ; steadying the larynx and trachea with the thumb and first finger of the left hand, I cut, not without much difficulty, through the cartilage and rings, when at once froth and mucus issued from the wound, and the sucking in of air told me that the obstruction, whatever it might be, could not altogether be below the opening. The immediate danger being in some respects now passed, I took time to look around, if not to breathe, for the operation had been performed before I had scarcely any idea that it had been begun : there being nothing in the shape of spoons, except big pewter ones, one of which of itself would have completely filled the wound, to keep the lips of the opening apart, I called for a smoking pipe, and breaking the stem three-quarters of an inch from the bowl, passed it into the trachea, and although the opening was certainly very small, there was still a sufficiency of air introduced to carry on the respiratory process ; the suffusion of the face began to decrease, the colour returned to the lips, and the cold and glassy appearance of the eyes gradually and slowly gave way to a more natural and less dreadful expression.

"Looking about me for something to act as a probang to explore the trachea, I seized upon a whalebone rib of an umbrella, and rounding off the end, passed it downwards to the bifurcation of the trachea, when finding everything clear in that direction, I next turned it upwards, when its progress was soon stopped by something which, for a moment, effectually prevented the further advance of the whalebone ; but I was determined that an opening should be made there, and that something ought to be removed : opening the old man's mouth, and pushing with considerable force from downwards, I fancied that glottis, epiglottis, and the components of the regional anatomy of the posterior fauces were being pushed up into the mouth. I now thrust in two fingers, seized hold of some substance, and with a good pull drew away a large piece of beef that had become firmly impacted in the rima glottidis. At once the trouble was at an end : the old fellow looked rather surprised, if not foolish, at the figure he was cutting, and staring at the laughing crowd, wondered what the trouble was, and why he was not eating his dinner. The edges of the divided integuments were brought together by two sutures carried through a large cambric needle, and a compress and bandage completed the dressing.

The next morning Davis returned to his quarters, and was quite well in a few days. When my bill was presented to the County Poor Authorities, I was allowed five dollars (because I had not been employed by them) for saving the poor creature's life, with the gentle hint that had I allowed him to die, they might have had no objection in paying the whole amount charged—fifty dollars—as I would have done myself and my 'fellow-citizens' a service as tax-payers, in ridding the county of a man who had been a burden upon it for over thirty years ! The poor fellow had seen hard service in Spain ; was wounded three times at the battle of Albuera; a ball passed through the shoulder, producing partial paralysis of the right upper extremity, and during the same action he lost sight of one eye : a few years after he became deaf, and to finish the chapter of his infirmities, in 1854 I removed one of his testicles for cancerous tubercle, and in 1857 a piece of tough beef came near putting an end to his precarious existence.

"The novelty of the accident, the promptitude of the operation and its unexpected success, together with the well-known name, if not history, of the old 'Britisher,' invested the case with more than usual interest, and the Editors of the three Plattsburgh papers called upon me for a few

notes, which were published under the head of 'Local Items.' A couple of weeks after, a copy of the 'Albany Argus' was placed in my hands, with the notice that a gentleman, dining at the Stanwix Hall in that city, fell back in his chair to all appearance dead: the medical man of the house was immediately summoned; he came, examined the case, diagnosed that something had lodged in the windpipe, and that he should have to go to his surgery for the necessary instruments. This he did, and returned with his armamentarium in about twenty minutes, when he found the man stone dead, and stretched out upon a table in a private room. An examination showed that a piece of beef had become impacted in the glottis, closing it and inducing almost, if not truly, instantaneous death.

"Another case in illustration of the criminality in not being prepared to meet emergencies. Dr Allen, of Rockville, Indiana, was sent for to go a distance of four miles in the country, to see a child, without being apprised of the nature of the ailment. On his arrival, he found out that tracheotomy was required; he rode back home for his instruments, and before his return the child had expired?—Gross, 'Foreign Bodies, &c.,' p. 208.

"When the danger in any case is so great and impending, it is not only folly, but culpable negligence, on the part of the medical man to wait till he has procured all his instruments, and, perchance, consulted some book to renew his acquaintance with anatomical facts and boundaries long since studied, and as long since forgotten: the patient dies, and although from the nature of the accident non-professional persons may not directly attach any blame to the physician, still the latter cannot entirely divest himself of the idea that he should have attempted the operation let the result be what it may.

"Another cause of postponement on the part of the junior practitioner, is the fear of performing this, as well as many other operations; and this, to a certain extent, is principally attributable to the course adopted by some teachers of surgery and anatomy, who clothe their descriptions of the various surgical regions, and the operations occasionally necessitated therein, with such anatomical niceness and minuteness, the innumerable difficulties to be encountered, the vast dangers to guard against, the whole shrouded in such a cloak of apparent forebodings, accompanied with *such* shrugs of the shoulders and knowing turn of the eye, as much as to say—though they truly mean it—'Boys, don't touch them; send them here; we are the men to do these things!' Many young men are literally *scared* out of the performing the most trivial operations, by the recollection of what they had heard and seen in the lecture-room. Well do I remember listening to the teachings of some most distinguished surgeons and anatomists, and with all eyes and ears, I was amazed at their erudition, astounded at their boldness, if not recklessness, in undertaking some of those grand operations which have shed such a bright lustre on their names, and made them the Napoleons of the Surgical World—the various steps of which they detailed with such *gusto*, led me almost to think that there were but few, if indeed any, who could, or had a right to perform such operations except themselves; and it is more particularly for this reason, that some of the surgeons of all large cities enjoy such a large country consultation and practice, as the young physician, either unwilling or unable to perform any operation, sends the subjects to the city, where they are always well received, and in some instances their expenses are not only paid, but a bonus is thrown in to secure the case.

"On another occasion I will make a few practical remarks upon the operation of Tracheotomy, and show that it is easily performed, far from dangerous, and, in the great majority of cases, followed with successful results."

The 'Lancet' opens with Mr Hilton's Lectures on *Pain and Rest* in accidents and surgical diseases, copious reports of which have already appeared in the Medical Circular. Dr Robert Barnes continues, in the same periodical, his observations on the value of the operation of *Turning* in labour obstructed through coarctation of the pelvic brim. We extract the case.

"Case 4.—On the 8th of March last, my assistance was required by a midwife of the Royal Maternity Charity in a case of obstructed labour. The patient—aged twenty-six—had borne one child before; the labour had been very lingering, but the child lived. I found her at 7 p.m. in labour at term. She was weakly and ill nourished; pulse feeble, and getting excited. She had been in labour twenty hours; the membranes had been ruptured eight hours, and it was represented that no progress of the head had been observed for five hours. The pains had flagged, and ultimately failed nearly entirely. I found the head lying on the brim in the transverse diameter, forehead to right ilium. The feeble contractions of the uterus had no effect in driving it into the pelvis. The apposition of the parietal bones to the pubis and promontory was very close; the occiput filled the left half of the brim, and in the right half a small space was left by the frontal part of the head. The head was movable, and, pushing it a little up, I took the dimensions of the pelvis. The conjugate diameter barely exceeded 3·25"; the two sides of the brim seemed equal, so that the circumference of the brim was kidney-shaped. On withdrawing my hand, I found it soiled with meconium. The fœtal heart could not be heard. Believing that moderate extractile and compressing force would bring the head through, I endeavoured to apply the Dublin forceps, but, owing to the shape and contraction of the pelvis, the instrument could not be made to lock. I introduced my left hand to turn. I passed this through the right half of the brim over the child's face. Laying my finger on the child's chest, I felt a pulsation, so feeble as to be almost doubtful as to its nature. Passing on, I felt the umbilical cord; there was no pulsation in it. I then seized the left knee. By upward counter-pressure effected by the right hand externally, pushing up the head, the leg was readily brought down. This being secured by a tape and held steadily, the evolution was completed by pushing up the head by the hand in the pelvis. The breech was soon born. The head was delayed at the brim; it entered in the transverse diameter, occiput to right ilium. By moderate force exerted for three minutes, pressure being maintained on the uterus externally, the head came through with a slight jerk. Whilst the head was in the brim, I felt a slight convulsive movement of the child's arm—the first sign of life. It was born breathless; not cyanosed; its limbs quite flaccid; no pulsation in the cord; a very feeble pulsation at the heart. At first, respiration was inexcitable. I kept up semi-rotatory movements for five minutes, with occasional cold aspersions over the area of distribution of the respiratory nerves. The heart began to beat rather tumultuously; respirations, at first imperfect and at long intervals, occurred. Presently, on dipping the body into warm water, and quickly withdrawing it, the child cried. Taken to the fire, it soon cried strongly, and seemed safe. It showed no depression on the skull or distortion, and the caput succedaneum was very small. The child was a female, of full size; head of ordinary dimensions. The placenta was cast in ten minutes.

"*Commentary.*—This case afforded me unusual satisfaction. It exhibits the superiority of turning over craniotomy in a new light. Here was a child saved, which, if auscultation and the escape of meconium had been relied upon as evidence of death, would, under the accepted doctrine, have had its head perforated. It may be urged that the child might have been delivered by natural pains stimulated by ergot. A first child had been born alive. But in women of defective organisation, exposed to hardships of poverty and toil, it is not uncommon to find the parturient power exhausted by the first labour. I think it possible that energetic uterine contraction might have sufficed to drive the head through the pelvis. But uterine contraction, and, indeed, the woman's general strength, had long given way before the obstacle. Ergot might have failed to rouse them sufficiently, and would, in all probability, not have done so at all under half an hour. Moreover, there was the risk of rupture of the uterus. My experience is not favourable to the attempt to lash the *exhausted* uterus into spasmodic energy by ergotic stimulation. The half-hour would have been a period of protracted suffering to the mother, and destruction to the child. The long forceps might have been successful. I entertain a strong bias—a prejudice, perhaps—in favour of delivery head foremost. But the forceps could only have been applied in the transverse diameter of the brim, one blade over the forehead, the other over the occiput, or a little obliquely. The grasp under such circumstances would have had the effect of causing the bi-parietal diameter of the head to bulge out more strongly against the promontory and pubis, increasing the disproportion and difficulty. The operation would have been severe, and the risk to the child great.

"I am satisfied that the delivery by turning was, in this case, the least distressing to the mother; admitting of being performed with greater ease and celerity than any other. And if we recognise the right of the child to a share in the appliances of Conservative Midwifery, then must this case be regarded as one of leading importance."

Dr Bree also reports a case of *Myelitis* and extensive spinal irritation, with paralysis of left leg. We give it:

"Susannah C——, aged thirteen, admitted into the Essex and Colchester Hospital, Feb. 24th, 1859. The following history, down to the middle of November, was obligingly furnished to me by Mr. Johnson, the house-surgeon:—The account this girl gives of herself is, that she has never had any particular illness until about two years ago, when she had fever, which laid her up for about seven weeks; but she has always been delicate. On admission, she complained of feeling weak, and being unable to follow her employment, that of factory hand. She states that she has been accustomed to work in a room heated by steam pipes, and that she was in the habit of fainting away at her work. She dates her present illness from running home one day in the wet, when she felt pain in the side, with slight cough, which confined her at home for a few days, when she resumed her employment for two days. She had medical advice, but received no benefit. On April 22nd (whilst in hospital), she had a good deal of pain in the head and back; and, on coming up stairs, she fell and lost consciousness, and remained insensible from 7 p.m. till 2 a.m., during which time she was very rigid, but did not struggle. On recovering sensibility, she felt pain in her left leg, which she attributed to rheumatism, and did not mention it until she discovered that she had lost all power of using it, and that it had no sense of feeling. About this time she complained of pain in her back. She was put under the influence of mercury, and had the tartrate of antimony ointment rubbed along the course of the spine. From this time she had attacks of insensibility about once a week, until Sept. 29th, when she left the hospital on five weeks' leave of absence, much improved in health. She was readmitted at the expiration of her term of leave, having had several of her old attacks, and was altogether not so well in health as when she went out. Her leg was now more particularly examined, when she was found to have neither motion nor sensibility from the knee downwards. The muscles and integuments of the thigh appeared scarcely, if at all, affected. She was ordered tonics and good diet, and the leg to be galvanised daily, and frequently rubbed with a rough cloth.

"The patient came under my care about the middle of November, and I continued the above treatment for another fortnight, without any benefit.

"On the 1st of December, I carefully examined the spine, which was extremely tender on pressure from top to bottom. So sensitive was this region, that she could not bear the slightest pressure without pain, and even gentle percussion made her cry out. This tenderness was more pronounced in the lower part of the dorsal region, just below the antero-posterior curvature in this situation, but not localised over any particular vertebra. She had had no fit since she came under my care. Her complexion was sallow, and expression dull. She had never menstruated. Appetite bad; bowels regular; urine normal. The left leg was completely paralysed below the knee, and insensible to pain. She could use the flexors of the thigh so as to bend it partly towards the abdomen, and there was no anæsthesia above the knee. I ordered her to have two grains of ergot twice a day, and the spine to be rubbed night and morning with a liniment containing extract of belladonna; the leg to be well rubbed

with the flesh brush, and the diet to be liberal, with moderate allowance of beer.

"The only alteration in this treatment up to the 25th of January, 1860, was that of increasing the dose of ergot to four grains after a slight appearance of the catamenia on the 22nd of December. After the first fortnight she began gradually to amend, and the notes in my hospital book are—

"Jan. 14th.—Begins to walk nicely without assistance; sensibility has in a great measure returned in the limb.

"23rd.—She is daily gaining more use of the limb; spine is still very tender.

"25th.—To be made an out-patient.

"On the 5th of February she walked up to the hospital from her residence in the town. She had quite regained the natural use of the limb, but the spine still remained tender. To continue the liniment, but omit the ergot. I have not seen her since.

"*Remarks.*—Now, what was the pathology of this interesting case? We have, in looking over the history, evidence of a lesion of the cerebro-spinal system and its consequences—loss of consciousness, tonic spasms, paralysis, anæsthesia. The spinal curvature I satisfied myself did not depend upon disease of the bony column, and the tenderness along this tract indicated, I think, inflammatory action, as well as that combination of symptoms, as Dr Brown-Séquard has it, termed 'spinal irritation.' I think it will be admitted that the amendment was entirely due to the treatment. It was founded upon the above view which I took of the pathology of the case, and upon the principles so ably set forth by Dr Brown-Séquard as to the therapeutical action of ergot and belladonna in the treatment of myelitis. In my notes of the lectures I heard delivered by that distinguished physiologist in Edinburgh, I find the following:—

"'Strychnine is almost useless in all lesions of the spinal cord, and especially hurtful in congestions of that structure. It acts by producing paralysis of the bloodvessels of the cord, and therefore in its lesions it can only increase the morbid effects. In sympathetic paraplegia, however, it is very useful. Ergot of rye and belladonna may both be used where strychnine cannot; they excite reflex action by acting upon the bloodvessels of the nerves.'

"In the summer of last year I saw two cases of myelitis with partial paralysis of the lower extremities, the bladder, and rectum, successfully treated with ergot of rye and belladonna by Professor Bennett, in the Royal Infirmary of Edinburgh, such treatment being founded upon Dr Brown-Séquard's views. I therefore venture to draw the attention of the Profession to the subject by the details of the present case."

Mr Holmes Coote contributes to the same journal a paper on the *Nature and Treatment of Deformities*, and Dr Richard Hughes an article on *Periodicity* as a character of disease.

The 'Medical Times and Gazette' contains a Lecture by Dr Goodfellow on *Bright's Disease*. We quote some of his remarks upon the chemical conditions of the urine:

"Thus we find by comparing the two sets of Tables—those of health, with those of disease,—that the proportion of urea ranges in health from 11 or 12 to between 32 to 33 parts in 1000 parts of urine, while in these affections of the kidney it is only found in one of the cases noted in the tables as high as 11, and this was when the quantity of water was much below the average proportion, and at the outset of the disease. In nearly every other instance it was found varying in proportion from 7½ to below two parts in 1000. The uric acid seems to undergo a less notable differenec. In health it runs from 0·391 to 1·098; in these diseases it varies from 0·6 down to 0·2. Another very important, but rather indefinite ingredient in the urine undergoes a great diminution in this disease—those substances called by chemists the 'extractive matters.' These are, however, important to us in connection with these diseases. These matters are, I believe, universally considered by chemists to have their origin in the metamorphosis of the tissues, and in the effete matters which are no longer useful in the body, but ought to be excreted from it. These matters in healthy urine vary from 10 to 16 grains in 1000. In these diseases they are reduced from 5 to 2 grains in 1000, being from ⅓ to ⅛ the usual proportion. The fixed salts also are diminished. In health they vary in amount from 11 parts in 1000, the lowest, to 16 parts or more, the highest; while in these diseases they vary from 11, the highest, down to 1·8, the lowest. There is also a great difference in the proportion of water. In health it varies from 981, the highest in any analysis, down to 932. In these diseases that we are now considering, it runs from 948, the lowest (and in this case it was in the earliest stage and the most acute form of these affections), up to 989. On the whole, the contrast in the amount of solid residue in health and in these diseases is most striking. In Berzelius it is 67·00 in 1000 parts, and in Marchand's 30 in health. In these affections it varied from 36·0, the highest, down to 10·9, the lowest. And it should be noted, in connection with this residue, that in Bright's Disease the amount is increased by the adventitious substances present,—albumen, casts of tubes, blood-corpuscles, &c.; so that the nominal amount of solid residue in these affections is greater than the real or absolute amount.

"So much, then, for the alteration in proportion in the natural constituents of the urine in these affections. What are the adventitious constituents? The first and most important is albumen. The quantity of this proximate principle is found, by the most approved analyses, to vary from 22·64 to 0·1 in 1000 parts. I need not here occupy your time in describing the manner in which albumen is detected in urine. Most of you are practically acquainted with it; and for those present who have not as yet been much in the wards, it is described in the 'printed instructions' in the case-books. It would be well, however, in some cases to weigh 1000 grains of urine, and filter, to separate extraneous matters. Then coagulate the albumen by heat, wash and carefully dry it, and weigh. You will then discover yourselves, what was first pointed out by Dr Christison—namely, that although the proportion as estimated by its volume in the fluid is very abundant, it weight is insignificant. Ten parts by weight in 1000 parts of urine, will render it almost a thin uniform pulp when heated. Less than this is seldom met with in the early stage of the disease. The highest Dr Christison has found has been 27 in 1000. Here, as in all similar instances, heat converted the urine into a gelatinous mass, from which no fluid issued on turning the test-tube upside down. With reference, however, to the presence of this principle in the urine, I ought to state that it has been found occasionally in the urine in persons apparently healthy. Christison found it temporarily in persons after eating plentifully of cheese, pastry, and other indigestible articles which are known to have the effect of increasing the solid ingredients of the urine. He has found it also follow the application of a blister, when this happened to have given rise to renal irritation; when the system has been effected by mercury also. When I come to speak of the blood, you will find that not only is albumen occasionally present in the urine in apparent health, but that urea is present in the blood under the same healthy conditions.

"Rayer has detected albumen in the urine in pregnancy; and this is the state most calculated to mislead as to its true cause, because in many cases there is more or less œdema of the feet and ankles. But, knowing as you do the symptoms of these affections, and the way in which the anasarca makes its appearance, I apprehend that you will have very little difficulty in ascribing the presence of albumen to its true cause. Many have detected this principle in the urine in the crises of some fevers, in inflammations of the thoracic organs, in acute articular rheumatism, intermittent fevers, typhus, measles, and especially cholera. In gout also it may frequently be observed. But in all these cases its presence is not permanent.

"Besides the albumen and other constituents of the serum of the blood (for I look upon it that its presence in the urine is principally owing to a simple transudation of the serum into the uriniferous tubes and Malphigian capsules), we may have the blood-corpuscles and blood-casts, fibrinous filmy matters and casts of tubes, epithelium particles or epithelial and other kinds of casts, granular, fatty, wax, and so on, and occasionally (and especially in advanced stages) puriform mucus-globules from the urethra, bladder, uterus, and even pelvis. Now these casts and adventitious constituents, with the exception of albumen, are only to be seen by the microscope, and to recognise them with certainty is one of the most valuable accomplishments which you can attain; and I would emphatically recommend you never to lose an opportunity of making yourselves practically acquainted with these casts—measuring their diameter, and so on. Here are diagrams of all the different forms. But no diagrams will convey an idea of their appearance under the microscope like that which you will derive by examining the tube-casts themselves, as well as the other constituents, the different kinds of epithelium, the tessellated and columnar from the bladder, the columnar from the ureter, the smaller and fine tessellated from the pelvis, the globular and glandular from the convoluted tubes, and the same kind of epithelium but somewhat flatter and more resembling the scaly variety in the straight tubes. Of course, with this you may have both scaly and columnar epithelium from the urethra, and this last and the vagina. It is important also to be able to recognise the extraneous matters that are always found in the urine, such as cotton fibres, blanket, hair, &c. But a perfect acquaintance with the casts is essentially necessary, for it is by the character of these casts, when taken in conjunction with the history and symptoms, that you will be able to discriminate the several affections which we are now considering, and which I shall describe more at length in a futnre Lecture."

Some observations on the condition of the blood follow. Dr John Conolly continues his *Recollections of the Varieties of Insanity*, and Dr Meadows reports the following unusual case of the delivery of a living child weighing more than eighteen pounds. He says:

"I am induced to record this case because, so far as I know, the child was the largest ever born, and certainly the largest ever born alive.

"I was called on the 13th instant at 10 a.m. to Mrs K., aged thirty-five, who was in labour with her second child. She stated quite positively that she was at least a fortnight over time; and she fully expected to have twins, as she was such an enormous size, and had been greatly inconvenienced thereby for the last month. Fœtal movements had sometimes been so strong as to be quite painful.

"The present labour began at 6 a.m., with pain which regularly increased up to the time of my visit. The membranes were still entire. On examination, I found the parts soft; the os uteri dilated to about the size of a shilling, but I could not make out the presenting part, the child being still very high. By the abdomen I believed I detected the head at the fundus, with the back of the child looking forwards. Auscultation gave distinct evidence of fœtal life, for, notwithstanding Dr Adams's disbelief in the use of the stethoscope in pregnancy, I am still disposed to have some faith in my own ears.

"I left the patient, desiring to be sent for should any urgent symptoms arise. At 10 p.m. I made another examination, the labour having so far gone on steadily and well. The membranes were still entire. I now made out a breech presentation. The os was well dilated and soft, the patient in good condition, and the pains regular and strong. The breech descended but very slowly, and seemed, notwithstanding powerful uterine action, much jammed in the pelvis. However, at 4 a.m. on the 14th it had so far descended as to enable me to get a purchase on it with the fingers hooked round the groin, and with strong efforts I succeeded, at 5.30, in bringing down the breech and lower extremities. The cord was pulsating. Great difficulty was now experienced in extracting the head, but after some little force I had the satisfaction of bringing this down, and in a few minutes the child recovered and breathed comfortably.

"All the lower part of the body and thighs were of a deep purple colour, as if violently bruised, but the child was otherwise well. The placenta was expelled in half an hour, and the mother subsequently did well.

"I called five hours afterwards, and to my

surprise found that the child had died suddenly about an hour before, while lying at its mother's side. No reason could be given for this, as a short time before it appeared quite well. No post-mortem examination was permitted. On weighing the child, it was found of the enormous weight of 18 lbs. 3 oz. Its extreme length was 32 inches; the circumference of the head, 17½ inches. These are post-mortem measurements. It was most perfectly formed and beautifully developed. The placenta was of proportionate size, and weighed 3 lbs."

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 26, 1860.

F. C. SKEY, Esq., President, in the Chair.

A paper, by Dr C. J. B. ALDIS, was read, on

A CASE OF BRONZED SKIN CONNECTED WITH DISEASE OF THE SUPRA-RENAL CAPSULES.

Robert B——, aged twelve, was admitted under the Author's care as a patient at the Surrey Dispensary on March 29, 1859, with the following symptoms:—The body generally was of a dark olive colour, and the pulse feeble, with occasional vomiting, pain in the back, languor, and disposition to lie down. The eyes were sunken, and the conjunctivæ pearly white. The illness commenced about four months previously, at which period he was in very good condition. The discolouration of the skin had been noticed during two months; soon afterwards the urine began to dribble away, and loss of flesh supervened, with extreme prostration. The Author, believing the complaint to be that mentioned above, placed the patient under Dr Addison's care, at Guy's Hospital, on August 17, who confirmed the diagnosis made before he entered that institution. The complaint having proved fatal on August 20, 1859, Dr Wilks, who took much interest in the case, kindly sent an account of the post-mortem examination to the Author. A model was made of the diseased organs. The body, spare and universally tinged of a brown hue, presented no disease internally, excepting in the supra-renal capsules, which were converted into a tough yellow matter, their original tissue having entirely disappeared.

A paper, by Mr JOHN F. FRANCE, was read, being a

REPORT OF CASES ILLUSTRATING THE USE OF FORCEPS IN EXTRACTION OF CATARACT.

The object of the present report is to illustrate the advantage obtained by employing forceps, in addition to the ordinary means of fixing the globe, in extraction. The Author, after glancing at the need felt for some such auxiliary from the earliest introduction of this operation to the present time, as proved in a former communication on the subject in 'Guy's Hospital Reports,' pointed out the casualties to which defective command of the globe is apt to give rise—viz., premature escape of the aqueous humour, faulty section of the cornea, injury to the iris, loss of vitreous humour; and, in short, from various sources, jeopardy to the ultimate issue. He then briefly explained the mode of using forceps for the purpose in view; and, having noticed the complete command of the eye obtained by this means, proceeded to a condensed recital of twenty-one cases not hitherto published, exhibiting the practical working of his suggestion. These examples comprised every one, without exception, in which the Author had performed extraction, from the date of his previous publication to that of the twenty-first case; and, in collating them with the former series, he showed the infrequency of the accidents above adverted to, and the high average of success under the plan recommended. The Author claimed weight for the extended evidence thus yielded by a catena of forty-one examples, affording as they do the strongest testimony in favour of the method of operating in question; and, in conclusion, quoted the report of Dr Steventon, of Cheadle, who speaks highly of the advantage he had himself derived from adopting this method, and acknowledges the increased success he had met with since doing so.

Dr T. GRAHAM BALFOUR laid before the Society a

CONTRIBUTION TO THE STUDY OF SPIROMETRY.

The Author's investigations confirm the observations on the vital capacity of the lungs in Mr Hutchinson's paper, read to the Society in 1846. He gives the results of the measurements, by the spirometer, of the recruits, 1,126 in number, enlisted into the Grenadier Guards between October, 1848, and March, 1853, with the mortality and invaliding among them from the dates of their enlistment till the end of March, 1854. After certain corrections pointed out by the Author as necessary to render a comparison accurate, the results of the measurements in the Guards are almost identical with those made by Mr Hutchinson, as will be seen by the following summary showing the average "vital capacity" of men of different heights:—

—		Height of Grenadier Guards.				
		5ft. 8in.	5ft. 9in.	5ft. 10in.	5ft. 11in.	6ft.
Vital capacity	Balfour	231·5	239·8	245·6	251·5	258·9
	Hutchinson	231·5	240·5	245·5	252·0	258·8

The Author observes that the identity of these results is very remarkable, and may fairly be accepted as evidence of their accuracy. He next examines the question whether a low vital capacity may be taken as an indication either of a tendency to pulmonary disease, or of a feeble constitution, rendering the individuals liable to a high rate of mortality. To test this, the men have been divided into three classes, according to the extent of their vital capacity, and the mortality in each class has been traced. The results show a most remarkable coincidence in the mortality of the three classes, the difference amounting only to 0·6 per 1,000 in favour of men having a vital capacity above the average. But a different result was obtained in regard to the men discharged as invalids, the number who became non-effective being much greater amongst those having a vital capacity below the average than in the other two classes. The Author next discusses the value of the spirometer in the selection of recruits, as indicating the men having a tendency to pulmonary disease, and points out the necessity, in such an investigation, of including the total loss arising from consumption, both by death and invaliding. The tables and calculations submitted showed that this loss is much greater among the men having a vital capacity equal to or above the average. From the results obtained the Author concludes that a vital capacity below the average may be considered rather as indicating a generally feeble organisation, less capable of resisting the deteriorating influences to which a soldier is exposed, than as evidence that a definite relation exists between the vital capacity and a tendency to pulmonary consumption. Although this conclusion would seem to justify the opinion that the spirometer might be advantageously employed in testing the fitness of recruits, the Author points out practical objections to it which appear insurmountable; but he admits that it might be useful as an indication to the inspecting officer of the necessity for a careful examination by the stethoscope in cases of a very low vital capacity among men coming forward for enlistment. Finally, he concurs in the views expressed by Mr Hutchinson of the practical value of the spirometer to the Medical Referees of Life Assurance Societies.

A paper, by Mr C. HANDFIELD JONES, was communicated by Dr H. BENCE JONES, being a

TABULAR STATEMENT OF SEVENTY-TWO CASES OF HÆMATEMESIS, WITH REMARKS.

The Author stated that the seventy-two cases of hæmatemesis contained in the table are all that have been met with among 2,500 selected cases of all kinds, and about 10,000 (speaking roughly) of all cases occurring in ordinary Medical practice. The chief practical points which a perusal of these cases suggests are—1. The number of cases met with in which the existence of gastric ulceration is a matter of great uncertainty, and in which one cannot avoid asking oneself whether the hæmorrhage may not be simply analogous to common epistaxis. That this is possible, even when the hæmorrhage is copious, is shown by the record of a case given by Dr Brittan. 2. The number of cases in which all complaint of dyspepsia was either absent or so slight that it would have been impossible to distinguish it from that attendant on gastric catarrh, gastralgia, or gastric debility. 3. The great benefit of a tonic plan of treatment steadily carried out. The paper was accompanied by a table in which are recorded, for each of the seventy-two cases, the age and sex of the individual, the period at which hæmatemesis occurred, any important events prior to the attack, the symptoms observed at the time, and the treatment of the case, with its result.

URINE SUSPECTED TO BE CHYLOUS.

The present case of chylous urine differs in some respects from that described in page 11 of the first volume of the 'Archives.' For the specimens of urine and for the following notes of the case we are indebted to Dr Milner Barry, of Tunbridge Wells, who has taken great trouble to discover the real nature of the affection.

CASE.—William Avery, aged ten, a staid-looking pale-complexioned boy, but fairly grown and nourished for his age, has always been delicate, his spirits outrunning his strength, but does not appear to have suffered from any serious attack of illness, until last summer, when hæmatemesis and discharge of blood from the bowels came on, after a school feast, where he had displayed too much prowess as a trencher-man. This illness passed off without, apparently, leaving any ill effects. Three weeks ago he began to suffer from constant weakness and vomiting. Soon after swallowing his food, he has to rise up from the table, and the food is immediately ejected from the stomach. He also vomits "watery phlegm" when he gets up in the morning. There is some tenderness at the epigastrium, but not to any great amount, and no pain complained of in any region. Coincident with the commencement of this attack of illness, he has been passing "milky urine," having never done so previously. It resembles milk more or less diluted with water, does not vary much from day to day or from night to day, seems to have no urinous smell, is acid, and usually about of the sp. gr. of 1018. After reposing for some hours, a cream-like layer forms on the surface, which becomes diffused again by agitation. By the application of heat or nitric acid, a scanty, curdy precipitate is produced. Shaken up with æther it becomes transparent, and a thin coagulum forms by repose between the ether and the urine.

This urine contained numerous oil globules, like those present in milk, and a substance possessing the ordinary reactions of caseine, and it appeared, therefore, very important to avoid all possible chance of being misled by imposition. Dr Milner Barry has been at very great pains to settle the question, but has not yet succeeded in satisfying himself beyond a doubt that the case is a genuine one of chylous urine. He has not actually seen the boy passing the urine, but has obtained the following statement from the boy's mother:—

"She positively states that she has repeatedly observed the boy passing the white urine. Several weeks before he had medical advice, she noticed that the water was white in the chamber-vessel of the little bedroom where he slept by himself. That she had seen the water white when he had made water in the court-yard behind the house. The white water and the dreadful sickness frightened her very much. When he sat down at meals they always had a basin at hand, but the sickness used to come on so suddenly that the contents of the stomach were ejected before there was time to lay hold of the basin. For the last few months the sickness has left him, and the urine has not been white, but he does not look well. She had seen him herself passing the urine."

Dr Barry goes on to say that "This is the substance of the boy's mother's replies and statements. If there is deception, it seems to belong to the boy, and to be motiveless. There is one point, perhaps, worth noticing, viz.: that in cottages of the labouring population in towns, milk is not very extensively consumed, and therefore it would not always be at hand to enable this boy to play the imposter. I asked to have some of the urine sent to me if it should ever become white again."

If this was a genuine case of chylous urine, it would afford much interest, as the fatty matter was in the form of globules, and not merely in a granular state. I have never seen a specimen of chylous urine in which the fat occurred in the state of globules like those of milk, but think it not improbable that such cases occasionally occur. The present instance cannot be regarded as conclusive, and Dr Barry hopes that before long he may be in a position to determine the nature the case with certainty.—'Archives of Medicine.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B — The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 8, 1860.

SPECIAL HOSPITALS.

When thought and enterprise exhibit a strong tendency to develop themselves in a particular direction, we may be sure that there a vacuum requires to be filled up. As certainly as water flows into hollow places, does the tide of opinion run into the voids of social life. When the water has reached its level, stagnation begins. Every new movement meets with opposition; because it is itself opposed to established facts, institutions, interests, and prepossessions. The very flourish of self-assertion with which new ideas and undertakings are heralded to the world, helps to organise against them all the slow-going, quiet-loving people, who are satisfied with things as they are, because perchance they have earned wealth and credit by their instrumentality. That "there is nothing new under the sun," is the favourite wise-saw of aged experience; and it always comes opportunely in aid of the equally venerable opinion, that the world is very well as it is, and cannot be bettered by the new-fanglements of young men and the saucy professions of adventurers. When we are young, we love the hubbub of fife and drum, and the sheen of bayonets and banners, and, marching step for step with the troops, fancy ourself a soldier; when we are old, we shake our heads at all this noise and vanity, and as we hear the drum beat, know its hollowness, and turn away our steps to our own door, where peace and contentment dwell with feather-beds, easy-cushioned chairs, and turkey carpets. There is nothing new in the Riflemen, or the proposed Toxopholites either: were there not Volunteers fifty years ago—and, for that matter, Bowmen too, as far back as five centuries? Pooh! the Nineveh ruins present us pictures of Archers defending their towers against bands of resolute assailants. As for straight shooting at a bull's eye, what can beat that of the man who labelled his arrow for "Philip's right eye," and hit it, too, with the only shaft he had the chance of sending?

But the Rifle is a specialty, you say; is it the better for that? It is only a new way of doing an old thing. And what will become of the regular army, we should like to know, if Riflemen become numerous? Why, the Guards and Line must be all Riflemen! Horrible thought! The art of military warfare consists in a knowledge of the organisation of armies—of strategy, drill, and the natural dispositions and idiosyncrasies of troops. A good aim, indeed, goes for something in the account; but any man in the ranks can take a good aim, so there is no necessity for Riflemen. Thus argues our antiquated old friend, Sir Stedfast Sticklebaek, who grumbles at every new thing, and believes with all his heart that the nation will go headlong to ruin if these novelties are not authoritatively put down.

A similar conflict of opinion is now waging between General and Special Hospitals. During these last few years there has been a rapid extension of the practice of Specialism, and therewith a smouldering feeling against it among the Staffs of the older Institutions—a feeling which has at length burst into a blaze We printed last week a Protest signed by some of the most eminent members of the Profession, denouncing the practice, and invoking the aid of the public to abolish the nuisance. Sir Benjamin Brodie's respected opinion was enlisted on behalf of the malcontents; but it is somewhat amusing to remark that Sir Benjamin makes an exception in favour of the Ophthalmic Hospitals; though what claims beyond that of relative antiquity these Charities can have upon the writer's benevolence, it is not easy to conceive. Ophthalmic Hospitals are as strictly special as Aural, Orthopædic, or Cancer Hospitals: why, then, should a lenient judgment be passed in their favour, when all other similar Institutions are unmercifully condemned? Is it possible that the fact that these Institutions have been and are officered by some of the most distinguished members of the General Hospital Corps, has influenced the decision of our surgical Minos? Lawrence, Guthrie, Bowman, Hancock, Critchett, and Walton, are names that cannot be scouted.

The opponents of Special Hospitals found their main argument against them on the plea that the pursuit of a Specialty tends to divorce the mind from the study of the general laws of the animal economy, and that, consequently, a Specialist is less likely to advance a knowledge of his art than a general Surgeon, who has at the same time all descriptions of cases under his care, and has therefore larger opportunities of observation and comparison. This is a plausible, but by no means a satisfactory argument. It answers the purpose of those who want a plea for the justification of Special Hospitals only when they are officered by General Hospital men; in short, it is the argument of the thorough-going monopolist, who having already the General Hospital, would like exclusive possession of the Special Hospital too.

So far as the argument is worth answering, it may be met in this way: that all qualified men are already presumed to be well versed in physiological laws and the phenomena of disease generally, and that the extensive opportunities which a Special Hospital affords for the study of particular forms of disease enable a Surgeon to examine all the phenomena more completely and exhaustively than can be expected from a man whose mind is so much distracted by the endless variety of cases in a General Hospital, that he is quite unable to find time or leisure to devote his attention to unravel the intricacies of any one order of maladies. We ask the General Hospital men themselves who happen to be connected with Special Hospitals, whether they have not received more instruction and experience from their Special Hospital, in the particular class of disease there treated, than from the more pretentious General Institution? Every man can predict the answer to this question. Should any one of these gentlemen, however, answer perversely in the negative, we can only reply that he is acting very dishonestly in retaining office in the Special Hospital.

Again, it is said that the General Hospitals afford adequate accommodation for all classes of cases. This is undoubtedly incorrect. Cases of stone, probably, are never turned away, because they minister to the reputation of the operator, and for these, therefore, there may not be a necessity for a Special Hospital; but it is not so with the large majority of cases, for which provision is made in Special Institutions. As for the financial argument, that does not deserve notice: if there were no Special Hospitals, the General Hospitals would be no richer. Some of them were poor before Special Hospitals were established, and poor they have remained.

Our conclusions upon this matter are, that Special Hospitals are beneficial, inasmuch as they provide an asylum for numerous poor persons who cannot obtain admission into the Charities instituted for general cases; that the collection of a large number of persons labouring under the same malady provides more constant and fuller opportunities for studying disease than are likely to occur at a General Hospital; and that the division of labour which is so efficient in advancing other arts and sciences is equally beneficial in the science of Medicine. We admit the possible evils of Special Hospitals, as stated by the Protesters; but they do not, in our judgment, counterbalance the advantages. Then it must be remembered that General Hospitals have their evils too; but we would not like to see those institutions closed on that account. There is no unalloyed good in this world, and he is a foolish man who expects to find it.

A final word upon this subject must be pronounced. There can be no doubt that there is a larger amount of available surgical talent

in our metropolis than our large Hospitals can employ; and this talent, finding itself shut out from a fair competition for distinction in the old paths of fame, strikes out into new and unauthorised courses. This is the pinch of the complaint. Our old Hospitals are exclusive and illiberal; at one time none could attain office in one of them unless he had been apprenticed to a member of the Staff; that practice has been abolished, but the evil is continued in another form, and none now can hope for an appointment unless he have been educated in the Hospital. John Hunter was ineligible in his time for St Bartholomew's, because he was not a pupil of one of the Surgeons; and a similar custom would have made him equally ineligible at the present day.

We are aware that general laws cannot be made to include special cases, and that all ambitious men are not John Hunters; on the other hand, it is unseemly to assail men for endeavouring to be useful, and to attain distinction in some unaccustomed way, who are inevitably excluded from an honourable rivalry in the beaten paths of fame. We think that it would be more decorous on the part of the General Hospital men, if they would leave the specialists to pursue their own course, unmolested by their jealous machinations.

Should a Specialist do anything derogatory to Professional honour, he is equally as amenable as any other man to the law that governs the whole body in such cases; but there we stop: we disapprove of the attempt to disparage Specialism as a mode of promoting Medical Science, believing most confidently that, ere long, we shall be indebted to it for most of the improvements that will increase the usefulness of our charitable avocations. We already owe it much, from anæsthesia to the ophthalmoscope.

SUMMARY OF THE WEEK.

THE EDINBURGH LICENTIATES AND THE LONDON COLLEGE.

A Committee of Edinburgh Licentiates have lately been successful in obtaining the erasure from the Medical Act Amendment Bill of a clause repealing the right, as conferred by the Medical Act, of the Licentiates of the other Colleges of Physicians to be admitted into the London College by the payment of a small fee. We congratulate those gentlemen on their success, as whatever tends to introduce Collegiate uniformity into the Profession will meet with our approbation. In a circular letter which the officials of this Committee have addressed to the general body of Licentiates, we remark these words: "You will probably have observed that the Medical press has failed to impart to its supporters a *single word of warning* of the attempt to deprive us of our legal rights." This assertion surprises us by its extraordinary inaccuracy. These gentlemen issued their first circular on July 17th, and one week *previously*, in the No. of the MEDICAL CIRCULAR dated July 11th, there was an editorial article on this Bill referring especially to the obnoxious clause.

We then said, "Let the Scotch and Irish Physicians look to this. It is the first step backwards to the old class system—if, indeed, we can be said ever to have advanced a step out of it," &c. "The Licentiates of the Scotch and Irish Colleges have a claim upon those bodies which, vigorously urged, cannot be treated with indifference," &c. &c. Thus, one week before these gentlemen began to move, we *warned* them of the attempt to denude them of their legal rights; yet they now state that such warning was not given. The omission has been on the part of the Committee, who failed to communicate their proceedings to the MEDICAL CIRCULAR, or, as we believe, to any one of the other Medical journals. We think that they are right in organising themselves into an Association; for, as we said on July 11th, "there must not be a sinister policy for Corporate aggrandisement to the injury of the Profession at large," and the best way to defeat such a policy is to be ever on the watch against it.

We have deemed it necessary to make these remarks in justice to this Journal, which has been ever foremost in pointing out the dangers of probable legislation, and denouncing the wrongs it may have accomplished.

THE ROYAL COLLEGE OF PHYSICIANS IN CHANCERY.

The College of Physicians and the Apothecaries' Society, having taken Counsel's opinion upon the right of the former body to create a new order of Licentiates, and each being satisfied that its own Counsel has given the just one, find no way of settling the antagonism but by a suit in Chancery. This might, of course, have been expected. No Corporation ever yet consulted a lawyer with a rational hope of escaping law. Law is a calculation of probabilities, and Counsel have an art of exaggerating the likelihood of particular probabilities to suit the case of their clients. This suit, it is said, will be a friendly one: we hope so, for it is not often that friendship is pledged in the Court of Chancery; and if it be, there is but a poor expectation that it will ever be redeemed.

ST GEORGE'S HOSPITAL.

The continuance of the *exposé* of the affairs of St George's Hospital has led to a correspondence in the 'Times' on the subject of the Out-Patients' Department. Our readers already know our opinion of this feature of our Metropolitan Charities, so that we need not dilate. A writer, however, signing himself "An Assistant," and representing himself to be one of the Staff of the Hospital, has very clearly pointed out the evils of the system as they affect, particularly, the Assistant Medical Officer. He shows that it would require six hours of hard, unintermitting work to see two hundred patients a week, supposing that only three minutes were devoted to all the new cases, which would amount to forty in number, and a minute and a half to each of the remainder; and he considers this apportionment not fair either to the patients or the Medical Officer, the latter being required to waste a large portion of his time and to employ his intellect upon a large number of trivial maladies. If the case be so bad at St George's, what must it be at St Bartholomew's, where it is boasted that 90,000 patients are seen every year? We have several times affirmed that it is impossible that this amount of work can be done by the Hospital Staff, and we challenge the Governors to prove that it can be properly discharged. We cannot help saying that we think this statement one of the most extraordinary mystifications, put forth as *bonâ-fide* work, which can be lighted upon in this great city. As it is, the duty falls with great hardship upon the shoulders of two or three Assistants. This is quite wrong.

THE WEATHER AND THE HEALTH OF LONDON.

Is it possible for an Englishmen to get through the year without grumbling at the weather? This is one of our constitutional maladies, breaking out in the form of rheumatisms, coughs, sore-throats, rashes, diarrhœas, and a general distemperament of humours, mental as well as bodily. Perhaps we should be seriously disappointed if we had not something to complain of, and should grumble at the monotony of our own satisfaction. So our best philosophy is to take the world as we find it. We cannot but feel some commiseration, however, for those unhappy people who have left our splashy streets to luxuriate under the umbrageous and floral beauties of Bonchurch, or to spread their limbs *sub Jove* upon the beach at Margate. Fancy pale ladies looking mournfully out of close casements upon the rain driving over the misty sea, or, determining not to be done out of their enjoyment, doing "all the sights" in a covered carriage, and consequently resolved to admire the scenery and believe themselves happy. As for us Londoners, we are getting used to it; we are told the crops are abundant, and accept the news as some compensation for the present famine-prices; but our greatest satisfaction is, that notwithstanding the unseasonable state of the weather, the amount of sickness has been low, and there is not at present any appearance of an epidemic visitation. August is usually our worst month, and we have now entered it with a cheerful expectation of a salubrious autumn. We owe something of this, no doubt, to the efficient ministrations of our sanitary officers, and to the fact that the unu-

sually large rain-fall has thoroughly purged our river, for the time, of its varied pollutions.

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

This Society has just concluded its anniversary meeting at Torquay. The meeting was well attended, and an animated discussion took place, as usual, upon the state and prospects of the 'Journal.' This is the thorn in the side of the Association, keeping up a festering sore past all associative surgery. That surely cannot be right which is the source of continual division and disquiet.

REVIEWS

The Management of Infancy, Physiological and Moral. By Andrew Combe, M.D. Ninth Edition, revised and edited by Sir James Clark, Bart. M.D.

Advice to a Mother on the Management of her Offspring. By Pye Henry Chavasse, F.R.C.S. Fifth Edition.

Andrew Combe was the pioneer of the cause of sanitary science in relation to personal hygiene. It was he who first stated the principles of the science in that pleasing style that made the subject popular, and induced a body of imitators who have only advanced beyond him by following out his indications. Sir James Clark could scarcely perform a more acceptable service towards the close of his professional career, than that of editing this book, and endorsing its sagacious counsels by his long experience. There is a sad want among the public of a due appreciation of the truths of physiology. It is a fact to be lamented, that young women become wives and mothers without the slighest preparation for the responsible duties they undertake by any preliminary instruction in these matters appertaining to their own and their offspring's health, which are absolutely necessary to be known to ensure an intelligent direction of the hygiene of the household, and of the physiological and moral training of the family. On the contrary, we fear that an unwise silence is generally observed upon these points, and the young woman is left to discover by her own sad experience that which she ought to have been taught from the experience of others. Were mothers more impressed with the importance of these topics, instruction in physiology would become a part of the general education of young women, who would then become better qualified to discharge the duties enforced upon them by the inevitable laws of Nature. Ignorance of these matters is not bliss, but sickness, pain, and premature death. We can scarcely believe that the households of the humbler classes—and of thousands, too, among the better classes—would be so dirty, unwholesome, and ill adapted to maintain the healthy action of the human organisation, if women were better instructed in the elementary laws of hygiene. The charge of the young especially rests with them; and it is an unquestionable fact that the enormous mortality among children is almost entirely to be ascribed to the ignorance or negligence of hygienic rules.

Hygiene is comparatively a new application of medical science, and even our own Profession is not yet sufficiently convinced of its importance. The only Medical School requiring a knowledge of hygiene from the candidates for its diplomas is the University of London; and it is only since the Crimean War that the officers of the Army have been expected to have a sufficient knowledge of sanitary science. Where human beings are grouped together in masses, there is a powerful tendency to the evolution of disease; consequently, preventive is of equal or even of greater importance than curative medicine. The history of all military campaigns proves this, and demonstrates the necessity of a careful study of all those conditions that generate and propagate disease.

Of the two volumes that head this article Dr Combe's has precedence, not only by priority of publication, but by its mere philosophical tone and spirit. Dr Combe sets forth the principles of hygiene in an easy and elegant style; Mr Chavasse follows out these principles in dogmatic instructions on every imaginable detail incidental to the management of children. Both works are good of their kind; the latter, perhaps, likely to be most satisfactory to a young mother who has no wit or judgment of her own, and wishes for a counsellor at her elbow to tell her how to put a pin into a napkin, and give her the reason why; the latter will be regarded as the hand-book of the science by the better-informed, laying down, as it does, sound principles for guidance, but not superseding individual judgment in points of detail. In some respects we think that Mr Chavasse's work would bear the use of the pruning-knife, since it gives occasionally very doubtful advice and sometimes descends into trivialities. For example:

"*Is there any objection to butter for children?*

"I myself can see no objection to it; on the contrary, if the child be healthy, I consider bread and butter more nourishing than dry bread, provided the butter be used in moderation. Of course, if too much be given, it will disorder the child's stomach and produce sickness. Hot buttered toast should never be allowed: nor should melted butter."

Why did not Mr Chavasse make his anxious mother inquire whether bread also was a good thing for children? Of course new bread would be pernicious, like hot buttered toast; but still the question would be open whether bread made from the best wheat, one day stale and spread with fresh spring butter, is a suitable food for children? The answer would, we anticipate, be, "I myself can see no objection to it." This *ex-cathedrâ* dictum would, no doubt, appease the anxieties of the young mamma.

Again, if change be required,—as no doubt it would be beneficial,—where is the propriety in a teacher of hygiene recommending an unhealthy site, or a farm-house as perhaps the best place, though it is nearly certain to be surrounded with dung-heaps and stagnant water? Why not a house in the country without the farm?

"*In an obstinate case of Hooping-cough, what is the best remedy?*

"Provided there be no active inflammation, change of air to any healthy spot; nay, *change* even to an unhealthy one frequently effects a cure when other remedies have failed. A farm-house is as good a place as can be chosen."

We observe that Mr Chavasse strongly urges that the child should, whether milk be secreted or not, be placed at the breast immediately after labour, or at most within twelve hours, and reapplied every two hours, should there be no milk, until it shall be secreted. As a general rule this advice is good; but we regret to find that there is no caution expressed against a useless perseverance when there is little or no milk, or the nipple too flat to enable the child fairly to seize it. Reiterated attempts under these circumstances are almost sure to induce thrush in the infant by mere mechanical attrition of its own lining buccal membrane—thence disorder of the primæ viæ and atrophy. Even grown persons are obliged to discontinue their efforts to draw such a breast by the abrasion of the mucous membrane—how much more so in the case of a young infant? In these and other points, Mr Chavasse, as it appears to us, does not surround his advice with sufficient precautions, and interferes a little too much with the duty of the medical attendant.

There is another remark in this book which we correct for the sake of biographical accuracy. Speaking of the failure of mental power in precocious children, Mr Chavasse says:

"The young Roscius, who made such a noise in the world some years ago, and whose brain was overworked, when he grew up to man's estate lost that remarkable genius for which his early life had been distinguished. Had his brain been spared when young, when the excitement of youth had worn off (as then there would not have been that danger in study), he might have improved his intellect, and he might now (if he be still living) have possessed talents to have delighted and enraptured mankind."

This young Roscius died three or four years ago at a ripe old age, and in the last year of his life we had the satisfaction to hear him recite one of his most striking passages with all the fire and power of which he was ever capable. Having grown very plethoric, his energy was more alarming than agreeable. The miracle consisted, not in his being so great an acter absolutely, as in being so great a one for a youth. His style was not reflective, but impassioned, and therefore was not improved by age. Hence his failure. He was, however, always fine. We suspect that many similar anecdotes that are current in books would prove to be equally baseless if the facts were accurately stated. Facts are too commonly tortured to suit the Procrustes' bed of doctrine.

Here are a few paragraphs, however, which have our cordial assent. We quote them with the greater willingness, as we should like to deal a strong blow at the brutal practice of flogging which is now the rule in schools, and which has recently culminated in the horrors of the Eastbourne bedchamber.

"*Do you approve of corporeal punishment in schools?*

"I do not: I consider it to be decidedly injurious both to body and mind. Is it not painful to witness the pale cheeks and the dejected looks of those boys who are often flogged? If their tempers are mild, their spirits are broken; if their dispositions are at all obstinate, they become hardened and wilful. A boy who is often flogged loses that open ingenuousness and fine sensibility so characteristic of youth. He looks upon his school as his prison, and his master as his gaoler, and, as he grows up to manhood, hates and detests the man who has flogged him. Corporeal punishment is revolting, disgusting, and demoralising to the boy, and degrading to the schoolmaster as a man and a Christian. 'So far am I from holding with the dictum, Spare the rod and spoil the child, that I believe there are more children spoiled, rendered dogged and bad, and put into the wrong way, by the application of personal chastisement as a panacea for all evil—I believe many more moderately good children have been thus made perverse and incorrigible, than perverse children have been rendered mild and docile by the softening influence of the omnipotent stick. The French law forbids flogging children, except in extreme cases of rebellion.' 'Do not leave hearts to ache and break when it depends on yourself; nor, by impatience and passion, cause unnecessary personal chastisements to be inflicted, which only debase the mind and harden the disposition.' A writer in the 'Dublin University Magazine,' in speaking of his schoolboy reminiscences and of a master fond of flogging, makes the following pithy remarks:—'I said he had done much to harden the feelings of children—to create bad men therefore; I said that it had been well for all of us, had Mr Rarey appeared long since in the school-room, instead of the stable. At ten guineas per pupil, he might have taught tutors the secret of governing children, as well as horses—by kindness. He might have told them to approach the boy gently, to pat him on the head, to be quiet and kind with him, and to conquer

his timidity. Did the boy appear restive, and inclined to rebel, he might be softened by talking quietly—very quietly—to him. By degrees the school-room Rarey would gain an ascendency over the boy; the child's heart would be touched, and he would follow his master most cheerfully. This Rarey doctrine taught in school-rooms might bring a goodly fortune to a bold professor. It may be said, that I am travelling out of my province in making remarks on corporeal chastisement in schools. But, with deference, I reply, that I am strictly in the path of duty. My duty is to inform you of everything that is injurious to your children's health; and corporeal punishment is most injurious to the health and happiness of children. It is the bounden duty of every man—and of every Medical man especially—to lift up his voice against the abominable system of flogging, and to warn parents against sending their children to those schools where flogging is permitted."

We shall now leave these books; and omitting from view minor faults, we may justly say of them, that they comprise everything that can be said on the subject of which they treat, and that what is said is said well and pleasantly.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 78.)

In the winter of 1755, William admitted his brother into partnership in the anatomical lectures, a portion of which John undertook to give, and also to take the Doctor's place when occasionally absent by the demands of his increasing practice. No doubt he felt the disparagement under which he laboured in delivering lectures from the same chair in which the oratorical abilities of Dr Hunter were conveyed to the same audience. He always performed this office with great difficulty, and certainly no man was less qualified to undergo such comparison and rivalry. Fortunately there were two opportunities of competition, and two fields of emulation, in one of which John was unrivalled. His dexterity, accuracy, and skill in dissection, and preparation of specimens in anatomy and natural history—a department at that period very little known—aided by his careful and painstaking demonstrations in the public lecture-room, were perhaps more convincing and important than the textual correctness and didactic eloquence of his brother; the specialty of John, in his public lectures, being simply practical. His capacious mind made this a physical circus in which to expend his energies, and to give vent to the realities of science by displaying the relations and types of comparative anatomy, which afforded him subjects for deep and profound inquiry and investigation during his whole life. Even his hesitations, doubts, and delays were virtues, and, perhaps, if properly estimated, manifestations of genius and judgment in grappling the mysteries of Nature. The subjects John Hunter investigated to the present day remain in doubt and unsettled, and have progressed but little since he put his mark upon them. Being no reader, he knew little of the opinions and labours of others until informed by third parties, and could with great difficulty coin language to convey and express his own; in short, so much perplexity and obscurity frequently occur and pervade many of his views, that it was stated that he did not himself understand them. In his pursuit of inquiry, he was often injudicious and intemperate, but always sincere, honest, and laborious. Abernethy says of him, "He had received but little education; his mind had not been taught to act in imitation of others; he disliked to read as much as he liked to think, and had a tendency to distrust opinions, and examined every subject for himself." Mr Cline also observes that "he (Hunter) used to say his delight was to think." Not content with the discoveries of contemporaries or predecessors,—of Haller, Ruisch, Malpighi, Meckel, Morgagni, or his brother, he did not limit the field of his labour to surgery or pathology, but boldly approached, through comparative anatomy, the higher laws of life and physiology.

To forward this strong passion for natural history, he cultivated a good understanding with the keepers of menageries, and of the wild animals in the Tower. To conciliate and secure their good will and amity, and to obtain specimens, he sent them numerous curious animals, which had been given to him, or which he had purchased while alive, on condition that they would allow him to dissect and make preparations of them after death. He thus prosecuted inquiries into the types of organisation—the analogies that would help to unravel the difficult and complex functional combinations of the human machine.

Sir Everard Home, in speaking of John Hunter's labours at this time, says: "Mr Hunter worked for ten years on human anatomy, during which period he made himself master of what was already known, as well as made some additions to that knowledge. He traced the ramifications of the olfactory nerves upon the membranes of the nose, and discovered the course of some of the branches of the fifth pair of nerves. In the gravid uterus, he traced the arteries of the uterus to their termination in the placenta. He was also the first who discovered the existence of the lymphatics in birds." On another occasion Sir Everard, in speaking upon this subject, says: "Of the wonderful extent of these labours some idea may be formed when I state, from good authority, that the records of them occupied no less than nine volumes in folio, and a tenth on the natural history of vegetables. This is the more wonderful when it is conceded that he was extensively engaged in the practice of an anxious and laborious profession." (*a*) His collection of comparative anatomy cost him more than 10,000*l.*, and he spent 2,000*l.* in purchasing dead animals. Before going abroad he had been present at the dissection of more than 2,000 bodies.

The great devotion of John Hunter to the museum and the labours of the dissecting-room inflicted the usual penalty of untiring application, and in 1760, in the thirty-second year of his age, symptoms were manifested which demanded serious regard, and a milder climate was recommended to counteract incipient symptoms of pulmonary consumption. Having an appointment as Surgeon on the Staff conferred upon him through Mr Adair, John Hunter in the following spring embarked with the army for Belleisle; which circumstance brought the talented Mr Hewson in connection with Dr Hunter, as his assistant, during this necessary but temporary absence. For three years John Hunter remained in the Service as Senior Surgeon on the Staff with the army in Belleisle and Portugal, during which he collected a series of important facts, materials for his valuable work on Gun-shot Wounds.

During his absence on military service, he took advantage of the many opportunities which offered to examine the bodies of those recently killed in combat, to learn the healthy structure of the animal economy in cases suddenly carried off in the vigour and prime of life, and also the character of the healthy secretions. On the return of peace in 1763, John Hunter came to England fully convinced of the superiority of his native land, and, at the same time, sensitively alive to the position of isolation in which he found himself, at the age of thirty-six, amongst active and successful competitors, in a large city, with only very limited means and few friends. During the short absence of two years, the place of John Hunter had been most ably supplied by Mr Hewson in Dr Hunter's dissecting-room, and in superintending the anatomical theatre and museum. Surgical practice at this time offered no opening for him, all the avenues having been occupied by successful men in family practice, amongst whom may be named Sharpe, Hawkins, Broomfield, Pott, and many others, whilst the practice of the army was carried from him by his seniors in the service. These were gloomy prospects; but the ardour with which John Hunter resumed his anatomical labours and pursuits was significant of the type of the man, and he soon resumed the teaching of practical anatomy and operative surgery.

Before we proceed in our narrative, we must pause to make a slight notice of that eminent anatomist, Mr Hewson.

William Hewson arrived in London from Cumberland in 1759, and attended Wm. Hunter's anatomical lectures, given at that time in Covent garden. Upon John Hunter going abroad to join the army, Hewson undertook to instruct his fellow-pupils in the dissecting-room of that school, for which he was paid. After the session he went to Edinburgh, and took with him letters of recommendation to the Professors, from Sir John Pringle and Dr William Hunter. On Mr Hewson's return to London, in 1762, he entered into partnership with Dr Hunter, gave some lectures, and received a share of the profits. Their lectures became well attended and prosperous; and upon the completion of the building in Windmill street, Mr Hewson required, and had, an assistant in his labours. This partnership continued until 1771-2, when Hewson, upon a dispute with Dr Hunter, left him, and commenced lectures on his own account in Craven street.

To record the many disputes in which the brothers Hunter were engaged would be unprofitable, and in bad taste. The memoirs published of William and John Hunter, numerous as they are, especially of the latter, are unsatisfactory, from the tone and temper in which they have been written. Biographers, contemporaneous or living nearly upon the period in which these eminent men flourished, prejudiced by the influences prevailing, have given either injudicious praise, or manifested an envious and jealous spirit unworthy of their indisputable talents. Thus, Dr Joseph Adams, who was the pupil and friend of John Hunter, gives a record of his life coloured with panegyric, generously proving his devoted attachment to the man. Dr Adams, nevertheless, was not blind to the infirmity, pugnacity, and irritability of John Hunter's character—of which, having lived with him, he must have often been an eye-witness, and not unlikely a victim, and had ample opportunities of appreciating his failings and disposition. His memoir—which is written in a good style, and proves him to have been a man of judgment and learning—deprecates these disputes and contentions, especially between the brothers John and William, and speaks of them with impartiality and unreserved censure. Mr Jesse Foot, on the other hand, who wrote a memoir of John Hunter couched in language of undisguised animosity and virulence, is nevertheless constrained to bear testimony to the indomitable labour, perseverance, and honest zeal, in pursuit of discoveries in physiology, anatomy, and natural history, of John Hunter. Mr Abernethy, Mr Cline, and Mr Thomas sought every opportunity to eulogise John Hunter,—often in that warm and sincere style charateristic of idol-worship. Mr Abernethy arrived on the field of labour and enterprise at the time, Dr Hunter and Percival Pott being dead, John was in the ascendant, when honours, emoluments, and even patronage lay at his beck. At that time his opinions were oracular; he was the last appeal on all occasions of dispute or difficulty, and his decisions were final. He, notwithstanding, manifested great hesitation and timidity both in public and private, as instanced on the occasion of the memorable trial of Donella, in the case of Sir Theodosius Broughton's poisoning by laurel-water, at Warwick, in strong contrast to the bold and unscrupulous evidence given on that occasion by the Professor of Anatomy at Oxford; and another for murder by stabbing at the Old Bailey In the first, his doubts and confusion rendered it impossible for the court or counsel to obtain from him any satisfactory conclusion or opinion; on the second, which was a very plain and clear case, the ingenuity and talent of one of the counsel, only by a leading question, stole from him an affirmative reply on cross-examination. In private, he was never satisfied with the results of his own investigations, inquiries, and discoveries; and the confusion displayed in his writings and language explain his long delay in publishing. Mr Abernethy's sympathies were genuine; he was a pet of John Hunter, and their temper and character were somewhat alike; and his enthusiasm was natural and creditable.

Mr Hewson, during his connection with Dr Hunter, had been prosecuting a series of anatomical experiments to elucidate his inquiries into the properties of the blood, which were published in 1771. Whether this was the subject of dispute between William Hewson and William Hunter is

(*a*) 'Hunterian Oration,' by Sir Everard Home, p. 30.

unknown. Two years after their separation, Hewson communicated several papers to the Royal Society, upon "The Lymphatic System in Birds and Fishes," which gained him the Copleyan Medal and election to the Fellowship of that body. These investigations—in which the Hunters and Monroes, and afterwards Cruickshank and others, were engaged—produced much contention and animosity. William Hewson's lectures became popular, and his amiability and mildness of manners conciliated numerous friends. Dr Adams, speaking of him, says: "Hewson was an able man, eloquent, diligent, and agreeable in his address; he was freely chosen on account of his industry and fitness for the purposes required." (*a*) He married a lady of considerable attractions and worth, who enjoyed the friendship of the celebrated Benjamin Franklin. Mr Hewson terminated a most promising career in his thirty-fifth year, from fever caused by a wound received in dissecting a diseased body. Franklin, while in England as delegate from the new Republic of the United States to negotiate the establishment of their independence, lived in Mr Hewson's family fifteen years; "in short, formed a part of it." Mrs Hewson, on the death of her husband, accompanied Benjamin Franklin to Passy, and resided with him in France, and afterwards took her family to Philadelphia, in America, to be his neighbour, where she died in 1792. (*b*)

(To be continued.)

HOSPITAL REPORTS.

GUY'S HOSPITAL.—July 17th, 1860.

Amputation of Thigh—Necrosis of Tibia.—Mr Hilton.

This patient, a man about forty-five years of age, had received injury of the left leg, in which the head of the fibula and knee-joint were implicated, and became diseased. About seven weeks since, the head of the fibula had been removed in hospital. On cutting down to the joint, pieces of bone and cartilage were found carious, necrosed, and eroded; but no communication had at that time become established with the knee-joint, by sinuses or otherwise; although considerable disease of integuments and tissues was manifested. After this operation, for a few weeks the knee-joint improved. Then a deep abscess formed amongst the tissues, communicating with the knee; and sinuses were also formed in the surrounding integuments and tissues. Mr Hilton performed the flap operation, under chloroform, at the lower third of the thigh, on the anterior and posterior aspects of the limb, in the usual way. Suture and water-dressings applied. Upon examination of the joint, the cartilages were gone, and bones diseased; but no communication existed with the fibula, as suspected.

Necrosis of Tibia—Removal of Bone.—Mr Hilton.

This patient had received extensive injury of the leg at its middle and lower third—abscesses formed, and several sinuses amongst the integuments and tissues, but no communication with the ankle-joint. After administration of chloroform, Mr Hilton made an oblong incision upon the anterior aspect of the tibia of between three and four inches, then a crucial one. On dissecting the flaps, he removed a piece of dead bone, about one inch long and one inch broad, with elevator and nippers, and then a smaller portion.

Tuesday, July 24th.

Amputation of Leg—Amputation of Conical Stump of Arm.—Mr Hilton.

The amputation of leg was done for extensive and long-existing disease of ankle-joint. This patient, an emaciated, bad subject, was operated on in the usual manner by the flap operation on the anterior and posterior aspects of the limb.

Conical Stump.

This patient, a young woman eighteen years of age, had the arm removed by amputation when a child, and it appeared to have formed a good stump. As the girl advanced in years, outgrowth of bone occurred—the bone continuing to grow after muscles and tissues had ceased; and the bone extended about an inch and a quarter beyond a mobile and well-looking stump, in all respects free from disease, deformity, or any signs of retraction. In consequence of this outgrowth, an extension of the thin cuticular tegument over end of the bone, by drawing the nerves with it, had induced great irritation and neuralgic pains: failure of health resulted. This stretched integument showed over it a blush, with a few inky spots here and there; indications of degeneration of tissues at those points, probably implicating the extremities of nerves. *Operation.*—Incision at end of the stump on each side of bone to give side flaps; sawing off bone about an inch within the stump, by dissecting back and retracting the muscles and integuments.

(*a*) 'Memoir of John Hunter.'

(*b*) A new edition of Mr Hewson's work 'On the Properties of the Blood' has been recently edited by Mr Gulliver.

ST THOMAS' HOSPITAL.—July 20th, 1860.

Lithotomy—Lateral Operation.—Mr Solly.

This patient, a fleshy, vigorous-looking man, about fifty years of age, in tolerably good apparent health and condition—Mr Solly thought he had been of free habits of living—was on the preceding week brought into the operating-room, and the lithotrite applied without discovering the stone. The stone was easily sounded to-day. Under the influence of chloroform, the lateral operation was done, in the same way as last week, by Mr Le Gros Clark, with a common knife for the external incision, and beaked knife to pass through the grooved staff into the bladder. In this case the beaked knife used was longer, straight, and not so convex on the edge. The stone (small) was brought away in two pieces with some delay and slight difficulty, appeared to be of phosphatic crust, and lithate of ammonia nucleus. Little hæmorrhage attended the operation, which was favourably over. This patient died at 3 o'clock p.m. on the following day. The boy operated on by Mr Le Gros Clark the preceding week goes on well.

KING'S COLLEGE HOSPITAL.—July 21st.

Removal of Diseased Lymphatic Glands—Resection of Elbow-joint—Amputation of Ankle-joint; Pirogoff's Operation.—Mr Fergusson.

Removal of Diseased Lymphatic Glands.

The lymphatic glands, extensively diseased in this patient, were situated below and partly upon the parotid gland, and directly over the carotid artrey; they had become hardened and enlarged. Mr Fergusson stated that, if left, they would have increased much in size. This operation, he said, was formerly called "extirpation of the parotid gland." Although seated near or upon, they had nothing to do with the parotid gland. He said this might have remained, perhaps, five years longer. After a certain time, the active or acute state of disease in these glands subsides into a passive, chronic condition; but, if left till much enlarged, from their position upon the carotid, Mr Fergusson said they would be dangerous to remove, and would go on to form deep-seated chronic abscess, or proceed to rapidly-extending ulceration. It is an awkward affair to detach and remove diseased and indurated lymphatic glands from such a locality; and the condition of ulceration they may assume is, if possible, even more embarrassing. Under the most favourable circumstances, they require to be very carefully dissected away. Mr Fergusson showed an extirpated gland. He remarked that, having no capsule, they require nice dissection in their removal. He said, "You saw in this wound a portion of a gland not removed, which I cut away afterwards. This patient desired not to have chloroform administered; but I gave it, to avoid delay from struggling in so delicate an operation. In the previous case of fistula—a slight operation—I did not give it, thereby avoiding what little danger attends the administration of chloroform."

Resection of Elbow-joint.

The patient, an intelligent-looking boy, about sixteen years old, of good appearance and condition, had disease extending amongst the soft parts and tissues into the elbow-joint. Mr Fergusson remarked that it showed more disease at present than it would upon much longer duration; being now in a state of active disease and inflammation,—if it remained five years or any longer period, it would exhaust itself, and become succeeded by a chronic state of disease. He further said, the longer the patients live, the diseased action becomes gradually more exhausted, and wears out. With it the system also becomes worn out; but they may survive for twenty years, and may even then be operated upon. This patient had suffered great pain, the indications of which might have been noticed in the careful way the boy carried his arm on coming into the room. By this operation of resection, you get what is called a false joint; osseous union is prevented, and a ligamentous capsule is formed amongst muscles and mobile tissues, which gives a greater sphere and limit of motion than by anchylosis, or osseous union, and we gain a useful limb.

This was a curious case. The cartilages were sound; there was no disease of cartilage. The synovial membrane had begun to be inflamed. Bones are rarely diseased—in short, they are never considered to be so—when cartilages are sound, and especially if the synovial membrane is not diseased. These diseases are generally considered to be curable. If you wait ten or twenty years, patient surviving such long suffering, you might have a cure of limb, but perhaps, and more likely, a loss of life. If the first, it would be with an awkward limb and stiff joint. In this case, incipient disease of synovial membrane already indicates future degeneration and disease of heads of bones. Mr Fergusson operated by the single incision, which seems now to be the mode preferred. He cut, guided by the line of sinuses, down to, and dislocated the elbow-joint; removed, with saw and nippers, the extremities of the bones, the condyloid of humerus, olecranon of ulna, and head of radius. The tissues and soft parts were extensively diseased. He said, in some parts of Britain this practice of resection in infirmaries is known nothing of to this day, and has never been heard of. Amputation goes on, or, all at once, we hear of an isolated case of resection which has been performed after twenty years of suffering which might have been avoided. We had a man who had his elbow-joint cut away at this hospital, who afterwards became a good sailor. Another case, a shoemaker, undergone this operation of resection of elbow-joint, became afterwards a good Crispin; and another, a young woman, became a good sempstress. These triumphs of surgery cannot be too highly cherished.

Amputation of Ankle-joint—Pirogoff's Operation.

This operation has received more notice and discussion than M. Pirogoff could have dreamed of. An operation which he has relinquished as a failure, or as not a safe one, has set all surgical Britain by the ears and caused plenty of ink as well as blood-shed. The want of faith of M. Pirogoff in his own operation may be probably explained by cases of frost-bites, of frequent occurrence in Russia, being cases upon which he may have declined to operate by the calcanean section. The low circulation and vitality in such cases might justify his want of confidence. But the controversy so much bruited is within small limits, and the envious rivals to whom the eminent Russian surgeon relinquishes his honours are really fighting for a shadow.

Some perform a given operation better in one way, and under particular circumstances, than another; and very few eminent surgeons slavishly copy or implicitly follow the mode of any other operator. The bone of contention in this operation has been between Dr Eben Watson, on the one hand, and Mr Syme and Dr Pirrie, of Aberdeen, on the other. It has turned upon the mode of operating *with* or *without disarticulation* of the ankle-joint. When the conditions of disease of the joint will permit, a better and quicker operation may be done without disarticulation than with dislocation, and a cleaner stump be given. It takes some time to dissect the skin of the heel from the os calcis. Perhaps greater safety may be also obtained for the arteries; but this is a matter for prompt decision during operation, and to be decided *sub litem*.

Pirogoff's is a more rapid operation than Syme's, and parts of low vascularity and vitality are less compromised and disturbed. It also gives a longer stump, and firmer, larger, and better pad to bear upon. The portion of calcaneum left on flap makes full 1¼ inch difference in length of limb; the difference between the amputated and sound limb being only at most half an inch. Mr Fergusson operated upon a woman about twenty-five years of age, under *narcotism*, in the usual way. He made the section of the os calcis from below upwards, instead of from above downwards, having

first disarticulated the joint. A larger portion of calcaneum was preserved than by Pirogoff; but Mr Fergusson found it desirable to slice off a small portion more, and also to gouge out a soft part of diseased os calcis. He then sawed off the articulating surface of the tibia and extremity of fibula, and both malleoli, and brought up and held the posterior flap *in situ* by ligature, applying water-dressings. Mr Fergusson spoke highly of M. Pirogoff and his operation. He observed that in this case the bones were very brittle, very little calcareous matter being deposited, which makes them soft, as he showed by cutting into them. He said this was not disease, but resulted from the limb having been out of use for a length of time, and in consequence a sluggish secretion of calcareous matter.

GENERAL CORRESPONDENCE.

THE BATH.—HOT AIR *VERSUS* VAPOUR.

To the Editor of the Medical Circular.

SIR,—Having personally observed the construction of the improved form of hot-air bath built by Dr Barter, and experienced its salutary influence, I can recommend any medical gentleman disposed to patronise and support these improved thermo-electrical baths to visit Dr Barter at Blarney, where he can see the imperfections of the first Turkish bath constructed under the direction of the gentleman who was the first to introduce them into this United Kingdom, and the improved form since erected, and then judge by comparison. The first bath erected being found imperfect, the remains of a Roman bath of ancient Britain were examined, from which Dr Barter was enabled to introduce the mode of heating adopted by the ancient Romans, and to abandon that Turkish innovation of admitting vapour. The question next to be considered is—Are hot-air baths to be preferred to vapour baths? In other words, is the ancient Roman hot-air, "dry-vapour" bath to be preferred to the modern Turkish humid-air or vapour bath? Which of them will aid Nature most in her efforts to eliminate morbid matters—pestilential poisons—from the blood? Which of them can refer back to the most glorious history—that of Rome or of Turkey? It is true that there were abuses in the ancient Roman, which the "Reformed Roman bath" will avoid and correct.

A few physiological facts established by experiments seem to me to decide in favour of the ancient, or rather the Reformed Roman hot-air bath, and against the modern or humid-vapour or Turkish bath, which I venture to submit for your consideration and that of your readers. It appears that the President of the Dublin College of Physicians, referring to the "deficiency of vapour" in these improved baths, considered this "a dangerous and serious mistake;" but, when rectified, he stated that "these baths will become most useful medical adjuvants." He published this opinion upon the report of another doctor, not in practice, without having personally inspected these baths. Such a statement can have little or no weight, until it be supported by personal observation and experience.

The great capacity of water and the little capacity of air for caloric is an important fact worthy of notice. It will take one pound of coal to heat one cubic foot of water one degree, and the same quantity of coal will heat 2,850 cubic feet of air one degree; which shows that water has a vastly greater capacity for caloric than air.

If ice (temperature 32°) be dissolved, its water, remaining at 32°, will absorb 142° of caloric, which becomes latent—lost in the change from ice into water.

When boiling water at 212° evaporates into steam or vapour, and remains at the same degree of heat, it will expand into 1,700 times its bulk as water (Pereira), and absorb and render latent 100,8° of caloric without any increase of sensible heat (Fownes). Here we have an example of the enormous capacity of water for caloric, and of the cooling power of evaporation.

For further proof of it:—The hygrometric thermometer was placed in the hottest room of a hot-air bath, in which the dry bulb indicated 150°, and the wet bulb 98°; but when water was poured upon the floor of the hot-air chamber, it became charged with vapour in consequence, and the wet-bulb thermometer was raised to 150° of heat, because the cooling process of evaporation was prevented. The human body, three-fourths of which is supposed to consist of water, represents the wet-bulb thermometer; so that whatever prevents the evaporation from respiration and perspiration must increase the temperature of the body. Dr Marshall Hall stated that respiration and perspiration are cooling functions. It is also estimated that if evaporation from the living body could be completely obstructed, the animal heat would in a few hours be accumulated and increased to the boiling point of water; but this being incompatible with life—impossible, it can only be estimated. Had the learned President of the College of Physicians reviewed this question with the scientific light I have now furnished, he never could have recommended a bath charged with vapour to be preferred to one of pure dry hot air, when taken with all the prudent precautions suited for each particular case, which are so scientifically prescribed in the bath rules or instructions that I have read in those establishments. For instance, if the bather feel any unpleasant fulness or pain of head, or difficulty of perspiration—dry skin, he is treated, like the wet-bulb thermometer, to some warm water poured upon his head and body, the evaporation from which into the dry hot air cools and relaxes him into a more pleasing and agreeable condition: but if the whole atmosphere of the hot room were charged with vapour, there could be no cooling evaporation; the animal heat should then increase to a fever heat; there could be little or no elimination of morbid matters—animal poisons—from the blood in such a sad state as this.

I perceive, in your Journal of yesterday, a report from the 'Transactions of the Academy of Medicine,' of a new system of bathing, by means of an hydraulic apparatus—"a hydrofère bath," which Dr Sales-Gilons has used for reducing water into spray, and in that condition to be introduced into the lungs. I shall only observe that whenever novel notions run contrary to the immutable laws of Nature, they may live, like French fashions or follies, for a day, but they can never stand the test of time. The stomach is the organ destined by Nature to receive food and medical remedies; the lungs, to discharge morbid matters, and to receive the pure air of heaven, which no proud philosopher of Nature can improve by any amount of spray beyond that which Nature supplies. I have just shown that if we overcharge pure air with an excess of moisture, we must obstruct the elimination of carbonic acid poison, and of other morbid matters, and prevent the purification of the blood by respiration from the lungs. Surely this hydrofère spray bath will not increase the elimination of carbonic acid poison from the blood through the lungs, which, Dr Marshall Hall stated, decreases after thirty years of age and under the influence of alcoholic liquors, and ceases entirely during collapsed cholera, because there is no animal heat or carbonic acid generated in that disease. The hot-air bath seems well calculated to eliminate carbonic acid and other animal poisons by respiration and perspiration, and thus aid Nature in her own efforts to purify the blood, "the life of the flesh."

The experiment by Berger and Delaroche throws clear scientific light upon this question of evaporation from hot dry air.

They introduced a porous vase, containing two wet sponges and a frog, into a furnace at 126°—143°. The temperature of the sponges and vase was previously raised to 101°—105°; that of the frog was 70°. After fifteen minutes the temperature of the vase, sponges, and frog was uniform—that of the blood, and remained so for two hours, so that the vase and sponges *fell* about a degree and a half and the frog rose 29° in fifteen minutes, and all three remained at from 20° to 45° *below* the temperature of the furnace, thereby showing the cooling influence of evaporation produced by high heat. It is on this principle that ices are baked. The ice being enveloped in pastry, the evaporation from the latter, on being baked, is sufficient to keep the ice cool and solid; so that the epicure, after thrusting his tooth through a burning crust, may cool his tongue in ice. (G. H. Lewis.) Evaporation of fluid is the most powerful means of producing artificial cold: for instance, when carbonic acid gas is condensed into a liquid and allowed to escape from a narrow aperture, the intense cold produced by the evaporation of a part freezes the remainder into a solid snow. (Fownes.) It is estimated that if evaporation from the living body were completely obstructed, the animal heat would in a few hours be increased to that of boiling water; but this high heat, being incompatible with life, can never be shown.

Having read your able review of Dr Markham's work on 'Diseases of the Heart,' I fully subscribe to your scientific sentiments, that "Medicine is on the threshold of great improvements." "Disease is not to be cured by drugs alone; but whatever influences the varied functions of the human body, is the philosophical way of regarding the practice of Medicine, and provides the only weapon that will extinguish quackery and prejudice." The Professor of Medicine of the Oxford University declared that to separate the study of Physiology—*i. e.*, the Science of Nature—from that of Medicine, was to reduce the latter to a mere empiricism." In Ireland an empirical prejudice seems to be industriously circulated by some few Medical Practitioners, who ought to know better, against the "Reformed Roman or Oriental Bath"—that of ancient Britain, although it is based upon sound scientific truth—"magna est veritas et prevalebit." This bath is not put forward as a panacea, but as one of the friendly allies of Nature, to *aid her* in the varied functions of the human body, and in her efforts to eliminate morbid matters; for she, after all, is the physician of all diseases; let no man usurp her powers or resist her efforts. I have seen some few patients maltreated for heart-disease by bleeding, blistering, and mercurials—a practice now deservedly exploded. I was called to one whom I saw dissolving down under mercurial alteratives and a perpetual blister over the heart for six weeks, given up to die in two days, but who overcame the mercurial poison and the prediction, which were given up for tonics, &c., iodide of iron having replaced iodide of mercury, &c. &c.

I perceive in a Dublin paper, the 'Warder,' 14th July, a letter from a surgeon, dated Chincha Islands, Peru, in which he dwells upon the impropriety of sending consumptive patients to Australia, in the forlorn hope that such a long voyage would improve their condition, whereas it only aggravates their state, and pronounces it a cruelty to send such patients in the last stage away from home, comfort, and the sympathy of friends, to perish miserably on board ship, in a cold, moist ocean atmosphere. "They, no doubt have a constant 'hydrofère spray bath.'" He concludes—"The insertion of this letter in your (Dublin) paper may be productive of much good, for the majority of the patients who fell under my care were Irish, chiefly from Cork and Dublin."

Here is a warning to those medical men how drive their patients out of sight, beyond the seas, to foreign climates, although they can have at home a warm atmosphere in a hot-air bath, better adapted to the physical strength and the pecuniary circumstances of each particular case, and which is found by experience to have such a beneficial influence in renovating the constitutions and recruiting the health and strength of many invalids.

In the hot-air bath, cold water to drink and hot air to breathe are the natural elements to promote perspiration, to purify the blood, and to cool the body by evaporation from the surface.

I am, &c.,

Sligo, 26th July, 1860. J. TUCKER, M.D.

THE DIETARY OF THE IRISH WORK-HOUSES.

To the Editor of the Medical Circular.

SIR,—As I observe by the newspapers that Mr Maguire, during a discussion which took place in the House of Commons the other day on the Poor-law Relief (Ireland) Bill, very forcibly and most judiciously called the attention of the House to the wretched state of the pauper children in the Cork Workhouse, wishing to know the cause why hundreds of the children in that establishment were suffering from scrofula—recommending that further Medical inspection was urgently required to ascertain the nature or cause of the calamity, and proposing that in all cases five out of the ten inspectors should be Medical men,—may I beg leave, through the medium of the MEDICAL CIRCULAR, to express my humble opinion as a Medical man, and to state that the principal cause why so much scrofula prevails

amongst the children confined, not only in the Cork Union Workhouse, but every other workhouse in Ireland, is through a niggardly and mistaken economy on the part of the Poor-law Guardians? There is not a morsel of animal food, fish, or flesh of any kind allowed to the poor inmates of our Irish workhouses from one end of the year to the other; so it is no wonder that scrofula should prevail to so great an extent amongst so many helpless and unfortunate children as are doomed to stop in them; and I consider that it would be a very great benefit, and even a kind of real luxury, to a great many of those poor creatures, were they only to be allowed a little dried fish, or salt herrings even, occasionally, instead of the cold, insipid, milk-and-watery sort of diet that is only afforded to them at present. This could be done at a very trifling expense to the Poor-law Guardians. But a great many, Sir, harbour the opinion that salt fish of every description is bad or injurious to the blood of children—a very erroneous opinion indeed, as far as my experience in the matter goes. No—salt herrings even, the most plentiful and cheapest of all kinds of fish, are both salutary and invigorating to the systems of those pale-coloured and emaciated children, and act also as a most powerful check upon the tendency towards scrofula and serous deposits. The poor of this country, and the Medical Profession, are under a deep debt of gratitude towards the right hon. gentleman, Mr Maguire, for having brought this very important subject so ably and prominently before Parliament. Yours, &c.,

AN IRISH SURGEON.

[This subject was referred to some months ago in the MEDICAL CIRCULAR. The condition of the paupers in the Cork Workhouse is disgraceful to a civilised community. Red herrings would no doubt be a "real luxury;" but animal food is a real necessity (not, however, in the living form of "carouges"), and the children ought to be provided with it.—ED. MEDICAL CIRCULAR.]

OUR NOTE BOOK.

INDUCTION OF PREMATURE LABOUR.

In the 'Louisville Medical Journal' for February, Prof. Henry Miller has an article upon the induction of premature labour and abortion, with cases. We refer to it for the purpose of quoting his method of using the *uterine douche*. He says, "For this purpose an apparatus was constructed according to the directions of the German Professor (Kiwisch), with only a slight and important variation, consisting of a tin box ten inches square, holding about four gallons, with an india-rubber tube, twelve feet long, attached to the bottom of the tin box by a screw and nut, and having a metallic tube, six inches long, affixed to its other extremity—the end of the metallic tube being fashioned like the nozzle of the common enema syringe. Instead of arranging the apparatus to act on the principle of the siphon, as recommended by M. Kiwisch, a stop-cock was adapted to the india-rubber tubing, about two feet from its metallic end. To put the apparatus in operation, the box must be suspended on a nail driven into the wall, near the ceiling of the room, say nine or ten feet above the floor; the india-rubber tubing must be screwed on, and the stop-cock turned, so as to prevent the flow of the water till it is wanted. The patient takes her seat on a stool placed in a bath-tub to receive the water; the metallic nozzle is introduced into the vagina, and in contact with the os uteri, and the tin box having been previously filled with water, the stop-cock is turned, so as to pour a continuous stream upon the os uteri until all the water in the box is discharged." Prof. Miller uses the water warm at first, and, if need be, subsequently alternates cold and warm. In the successful case reported, the douche was used but once on the first day. On the second, third, and fourth days, it was used twice each day. On the fifth and sixth days he used warm, and then cold immediately after, using the warm and cold douche each twice each day when labour set in.

The fact that the douche will sometimes fail in inducing labour, and the number of times it has to be repeated before success crowns the effort, will always operate against this procedure. We prefer the separation of the membranes, which can be done at one sitting, is usually safe when properly performed, and is always successful.—'American Medical Monthly.'

INFLUENCE OF THE MOTHER'S MIND ON THE FŒTUS IN UTERO.

In the 'Nashville Journal of Medicine and Surgery' for February, Prof. John M. Watson has an able article upon the influence of the mother's mind on the fœtus in utero. He believes the mother's mind may, under certain circumstances, produce changes in the organisation of the embryo in her womb, and the reasons for his faith are well stated. We have not the space to follow his arguments, and will content ourselves with stating his fifth and sixth propositions:—"5. The mind, when improperly employed, may develop premature puberty, premature ova, and premature menstruation, to which may succeed premature conception; and all the energies of both soul and body being directed to this uterine function, may not certain images, under strong mental excitement, be transferred to the embryo? Seeing that the mind can exert such remarkable and undeniable influences over the female organism, may I not add a sixth fact? 6. That the embryo is sometimes altered or changed in its organisation in various ways, through the mother's mind or imagination; or shall we admit the influence of the mother's mind over her in every other respect, and then exempt the organisation of the embryo from its influence?'—'American Medical Monthly.'

TRANSFUSION.

In the 'Chicago Medical Journal' for February, Prof. Brainard reports a case of amputation of the thigh in a feeble subject, in which life was temporarily saved by transfusion of blood. He says: "In order to obviate the danger from loss of blood, I had an assistant hold a bowl under the member at the moment of the incision; in order to catch the blood, and stir it, so as to separate the fibrin, the bowl was placed in another containing water at the temperature of 98°. When the bone had been sawed, and the small vessels secured, the patient appeared to be dying from syncope. I then fixed the tube of the transfusion syringe into the femoral artery where it had been divided upon the stump, and the syringe at the proper temperature; I charged it with the defibrinated blood, which had been actively agitated, so as to be of a bright red colour, and threw gently into the artery nearly all the blood which had been secured. A light tremulous movement followed, and for about a minute no change was perceptible; but at the end of this time the respiration and the action of the heart became more regular, and he was soon as well as before the operation. The blood thrown into the artery was just two ounces." We have space only to quote another practical remark in this connection. Prof. Brainard says: "The choice of the artery instead of a vein for the transfusion was made for these reasons: 1st. It obviates the danger of fibrinous clots passing to the heart. 2nd. It diminishes the danger of air-bubbles passing to the heart. These are the great dangers of transfusion." — 'American Medical Monthly.'

TONGUE REMOVED BY THE ECRASEUR.

In the 'New Orleans Medical News and Hospital Gazette' for February, Dr S. Choppin reports a case of removal of the tongue, for cancer, with the *écraseur*. The operation lasted fifteen minutes, and was accompanied with no hæmorrhage. The operation is usually accompanied with considerable hæmorrhage, and it is highly probable that the *écraseur* is, in such cases, a valuable surgical appliance.

WESTMINSTER HOSPITAL.—The Prizes, Certificates of Honour, and Medals, awarded to the successful competitors in the Medical School of this Hospital, were distributed in the Board-room of the Hospital on Tuesday last. Lord Charles Russell, one of the Vice-Presidents of the Hospital, presided, and, after a few appropriate remarks, distributed to the following gentlemen the rewards of their diligence and industry:—Mr F. Little—Certificate of general proficiency in subjects of first year's study. Mr A. W. Edis—Certificate and Silver Medal, for proficiency in subjects of second year. Mr F. P. Edis—Certificate and Silver Medal, for proficiency in subjects of first year. Mr A. W. Edis—Prosector's Prize Case of Instruments. Mr Wilson—Special Certificate for Anatomy. Mr Wilson—Special Certificate for Physiology. Mr Kempster—Special Certificate for proficiency in Physiology. Mr Wilson—Mr Clendon's Prize of Dental Instruments for proficiency in Dental Surgery.

SIR J. OUTRAM'S MINUTE
ON THE INDIAN MEDICAL SERVICE.

[We publish with much satisfaction the annexed Minute on the subject of the amalgamation of the Royal and Local Medical Services in India. As a part of a general question of vast political importance, it is no part of our duty to express an opinion upon the policy advocated by the writer; but we feel that the Profession generally are under an obligation to Sir James Outram for his generous testimony to the "noble and ill-used Service" whose particular interests he defends.]

67. There is one class of officers in respect of whom I would fain make a special appeal on this score, as they are a class which, to our disgrace be it said, has been treated with singular harshness and illiberality, alike by their Military and Civil superiors. I allude to the Officers of the Medical Department,—a body of men who not only are unsurpassed by any other body in the Service for professional zeal and skill, gallantry, and devotion to their duties, but have especially distinguished themselves by the success with which they have cultivated general science, and the earnestness with which they have applied themselves to the promotion of education and other philanthropic objects. These men, especially those of the Bombay Establishment, have been treated by us with such unfairness, that a late Physician-General of that Presidency, a man whose name is held in honour both in and out of his Profession—I allude to Dr McLennan—felt himself authorised to assure the late Lord Frederick Fitzclarence, that had any officer treated his dog-boy in the manner in which the Court of Directors and Board of Control had treated the Medical Service, he would have been brought to a court-martial and cashiered for dishonourable breach of faith. The Physician-General's illustration was a strong one; but, after explanation, its justice was admitted by the Commander-in-Chief, who thenceforth felt as warmly on the subject as the head of the Medical Department.

68. In behalf of this noble and *ill-used* Service, Lord Dalhousie made a generous interposition; and though his Lordship's efforts were at the time unsuccessful, his appeal was so forcible, and his general views have been so earnestly and ably supported by Lord Canning, that justice cannot long be denied them if the Army of India be kept a local one. But to the Medical Service amalgamation would be ruinous.

69. Than Dr Alexander, the Director-General of her Majesty's Medical Service, I am sure that no worthier or more honourable man exists. But he is only a man—of finite knowledge and human feelings. He knows the officers of his own Service—he knows that many of them are eminently deserving of that promotion which at present it is not in his power to bestow, but for which amalgamation would afford an opportunity. And, not knowing the men in the local Army, his partialities would needs be in favour of the men of his own Service, to an extent that would prove ruinous to the just claims of the Medical Officers of the local Service. And even if he should deem it his duty, on the first opportunity, to promote to higher grades those Medical Officers the seniority rules of whose service prevented their obtaining promotion for the same services as secured promotion for their more fortunate brethren of the Royal Army—the very number of promotions that have recently been made to the grade of Deputy-Inspector in the Royal Service would, for a considerable length of time, prevent him doing justice to those of the local Service whose names had been honourably mentioned by the various Generals commanding in the field. And ere these arrears of promotion were disposed of, the claims of those in whom as members of his own Service he naturally feels more interested would have again accumulated and pressed for favourable notice.

70. Amalgamation, then, would prove injurious to the moral claims and legitimate expectations of the Military and Medical Officers of the local Service to an extent which only very urgent public necessities could justify; and I have endeavoured to prove not only that no necessity has arisen for destroying the local character of the Indian Service, but that its destruction would, in many ways, be productive of injury to India. But I would not be understood as claiming for the offi-

cers of the local army any exclusive right to Staff employ. And in Appendix B to this Minute will be found a scheme, the adoption of which would secure for the various Staff and departmental offices of the State an amount of general professional and special Indian qualification of very high order. Throw these appointments open to expectant officers of the line equally with local officers, and this probably would tend, more than any other possible arrangement, to make Indian service popular with line regiments. The fullest and purest competition of a practical—not a pedantic—nature would be introduced; and the best men would be preferred to the best appointments. The efficiency of the whole Indian Service—line and local—would be increased; no new burdens would be imposed on the people of India that did not bring commensurate advantages; and no injustice would be done to those six thousand gallant and honourable gentlemen who have long, and faithfully, and successfully toiled in this land of exile.

APPENDIX B.

76. Medical appointments to local service to be by competition, as at present.

77. Medical Officers of the local forces to undergo the same course of instruction at the Military Clinical Schools, as Medical Officers of the Royal Service.

78. Their period of service to reckon from the date on which they are gazetted as successful competitors for Medical appointments.

79. To receive a free passage out to India.

80. To be equally with military officers eligible for all the appointments enunciated in paragraph 74.

81. Surgeons and Assistant-Surgeons in Medical charge of political offices and residences to be permitted, if so minded, to enter as probationers in the political department; and on passing a satisfactory examination to be eligible for permanent employment in that department.

82. When the exigencies of the Service permit, Medical Officers, having served two years in India—who have passed the Interpreter's examination in two Indian languages—who can produce testimonials from their military and professional superiors of undeviating good conduct, personal and professional—and who may believe themselves possessed of special aptitude for civil duties, to be permitted to attach themselves to a collector's or a magistrate's office for two years in the character of a probationer on the regimental pay and allowance of a lieutenant; and on creditably passing the same examination as is prescribed for civilians, to be eligible for permanent employment in the civil service of the State.

83. Under the same conditions to be permanently attached to the Public Works Department.

84. All Medical Officers who, after qualifying for employment in the Civil or Public Works Department, shall elect to be permanently attached to these Departments, and all Medical Officers appointed to the offices enumerated in paragraph 74, to be placed on a separate "List of Medical Officers on permanent extra Professional Employ;" their promotion to the (honorary) ranks of Surgeons and Surgeons-major, to proceed as if they were still on the effective list; their retiring pensions, as well as subscriptions to, and claims on, the Military Fund, to be regulated by their honorary rank; but their connection with the Medical Retiring Fund to cease on removal to the non-effective list—the amount of the actual payments already made by them being refunded without interest.

85. So soon as the state of the public finances permits, the following appointments to be made, for which Medical Officers shall be alone eligible:—

(1.) "Minister of Public Health" for each of the Presidencies, whose duty it shall be to exercise a surveillance over the sanitary (Civil) arrangements throughout the Presidency.

(2.) A "Sanitary Commissioner" for each Collectorate, whose duty it would be to devote his entire time to the sanitary welfare of the different towns and villages of the Collectorate (and to the performance of vaccination) under the control of the Minister of Public Health.

(3.) A "Sanitary Inspector" for each division of the army, whose duty it should be to devote his whole time and energies to the sanitary arangements and requirements of the various cantonments, barracks, forts, &c., within the division, under the orders of the superintending Surgeon.

(4.) A "Commissioner of Lunacy" for the whole of India, under whose general control all the Indian Asylums should be placed, till by the multiplication of these institutions sufficient duty be found for a Commissioner of Lunacy for each Presidency.

(5.) A "Registrar-General" for each Presidency, whose duty it should be to collect, tabulate, and analyse the vital statistics of India.

86. All the advantages above offered to the Military and Medical Officers of the Local Force to be extended to the Officers of the Royal Army so far as may be consistent with the Rules of the Royal Army.

THE MEDICAL ACT AMENDMENT BILL.

[CIRCULAR LETTER.]

London, July 27, 1860.

DEAR SIR, — We have much pleasure in announcing to you that the obnoxious clause has been struck out of the Medical Bill.

In our former note we were in error in assuming that it had passed the House of Commons. We were in time to get the alteration made at the third reading.

We are indebted to Lord Derby for our success; but Lords Chelmsford and Ebury most kindly intended to oppose it in the Lords.

The only other provision in the Bill of any interest is to render the office of President of the London College annual.

We received so many and such satisfactory replies to our former Circular, that we have deemed it proper to form ourselves into a permanent Association, designated "THE ASSOCIATED LICENTIATE PHYSICIANS."

A Subscription of 5s. per annum constitutes a Member—this will meet our necessary expenses, and enable us to communicate by circular any information we may obtain touching our interests. You will probably have observed that the Medical Press has failed to impart to its supporters a single word of warning of the attempt to deprive us of our legal rights.

We hope this step will meet your approbation, and that we may enter your name as a Member of the Association.

The Subscription may be forwarded in Postage stamps, or by Post-office Order, either to Dr JOHN GARDNER, 23 Montague street, W.C.; or to Dr DE LISLE ALLEN, 18 Hunter street, Brunswick square, W.C.

At a meeting on the 24th inst., a Committee was formed, of which every resident Licentiate in London may become a Member, and also any Country Member who may be in town on the days of meeting.

It was resolved at the meeting to take up the matter of titles, and we shall esteem it a favour to be informed of your views on the subject.

Your obedient servants,

JOHN GARDNER, Chairman,
23 Montague street, W.C.
DE LISLE ALLEN, Secretary,
18 Hunter street, Brunswick square, W.C.

By order of the Committee.

Births, Marriages, and Deaths.

BIRTHS.

FITCH.—On the 26th ult., at Chaddesley Corbett, near Kidderminster, the wife of Dr Fitch, of a son.

STEVENS.—On the 27th ult., at Biggleswade, Bedfordshire, the wife of Chas. P. Stevens, Esq., F.R.C.S., of a daughter.

ASHDOWN.—On the 30th ult., the wife of Geo. Ashdown, Esq., M.R.C.S., Northampton, of a son.

HALE.—July 17th, at Barrow hill, Staveley, near Chesterfield, Derbyshire, the wife of Thomas Fredk. Hale, M.R.C.S., L.A.C., of a daughter.

MARRIAGE.

DEAS—HEPBURN.—On the 31st ult., at Hollycot, Lasswade, Dr David Deas, C.B., &c., Inspector-General of Hospitals and Fleets, to Margaret, youngest daughter of the late William Hepburn, Esq.

DEATHS.

ATKINSON.—July 31, at New Cross, William Bold Atkinson, M.R.C.S. Eng., late of Margate, and of the R.M. West India Steam Packet Company's service.

BANKS.—July 19, at Newport, Barnstaple, Howard Ralph Banks, Surgeon Royal Navy, M.R.C.S. Eng., late Surgeon H.M.'s ship 'Cumberland,' Sheerness, aged 44.

BELL.—July 15, at Malvern, Worcester, suddenly, F. Bell, Esq., M.R.C.S., of Aldborough, Suffolk.

COLLINGWOOD.—Recently, at Greenfoot, Sebergham, Carlisle, William C. Collingwood, L.S.A. Lond, L.M. Edin.; late Surgeon H.M.'s steamship 'Bentinck,' aged 44.

DAVIES.—July 24, at Eldon row, Dolgelly, Griffith Davies, late of Canarvon, Student of Medicine, aged 19.

DAVIS.—July 22, at Pontypridd, Glamorganshire, Evan Davis, L.S.A. Lond., aged 51.

GAIRDNER.—July 24, at Northumberland street, Edinburgh, Susanna Tennant, wife of Dr Gairdner, F.R.C.S. Edin.

HENDERSON.—July 12, at Bankhouse, Stow, Edinburghshire, Robert Henderson, L.R.C.S. Edin.

MACLAGAN.—June 27, at Ruatan Bay Islands, Honduras, David Philip Maclagan, M.D. University of Edin., L.R.C.P. Edin., L.R.C.S. Edin., Assist.-Surgeon to H.M.'s ship 'Icarus.'

MACLARAN.—July 25, at No. 53 Schoolhill, Aberdeen, William Maclaran, M.D. Univ. Edin., L.R.C.S. Edin., L.F.P.S. Glasg.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS. — At the Comitia Majora, held on Friday, July 27th, the following members of the College were admitted into the Fellowship:—John Peet, M.D., Bombay; Alexander Armstrong, M.D., R.N., Hospital, Malta.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College, at a meeting of the Court of Examiners, on the 31st ult.:—William Alban Atwood, Aberystwith, Cardiganshire; George Bartlet, Culsalmond, Aberdeenshire; Thomas Bell, Uppingham, Rutland; Robert Thomas Burrows, Westbourne park place; Edmund Walter Coleman, Portsdown road, Maida hill; John Mark Bernard Grant, Newcastle-on-Tyne; Francis James Hammond, Sherborne, Dorset; Joseph Hocking, St Ives, Cornwall; Frederick William Houghton, Portsmouth; James Francis Lovegrove, Maidenhead; Henry Thomas Marsh, Upton-on-Severn; Robert Rosier Merry, Hemel Hempstead; Alfred Monckton, Brenchley, Kent; Evelyn Pocklington, Walesby, Notts; John Williams Pridham, Llanelly, Carmarthen; James Scott Sequeira, Jewry street, Aldgate; Absalom Harvey Smith, Palermo, Canada West; Mark Batt Tanner, Exeter, Devon; Henry Tofts, Cambridge.—The following gentlemen were admitted Members on the 1st inst.:—Thomas William Blake, Hurstbourne Tarrant; Edmund Henry Camerford, Kilkenny; Joseph Thomas Cape, Cheltenham; Henry Charles Chune, Colebrookdale, Shropshire; Douglas John Dutton, Bristol; Charles Hilton Fagge, Guy's Hospital; James Joseph Foley, Cork; Charles Ferdinand Keele, Highbury; Isidore Bernadotte Lyon, Euston square; William James Mallett, Bolton-le-Moors; Courtney Nedwill, Magherfelt; James Reid, Exeter, Devon; John Smith Crosland Richards, Bedford square; Robert Harman Smith, Halifax; Francis Patrick Staples, Wexford; Arthur Edwin Hutchinson Trotter, Stockton-on-Tees; Edgar Beckit Truman, Nottingham; Richard Williams, Kingston Bagpuize; William Henry Williamson, Wimbledon.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, July 26th, 1860:—Benjamin Evans, Duffryn, near Newcastle Emlyn, South Wales; William Gimson Gimson, Walton, Leicestershire; Henry Lewis Harper, St Luke's Hospital; Edwin Matthews James, Shrewsbury; Arthur Samuels, Eldon place, Liverpool.—For Assistant:—Edward Lee Bailey, Maida vale.—The following gentlemen also on the same day passed their first examination:—Decimus Currie, King's College; William Date, King's College; Edmund Gwynne, London Hospital; Bartholomew Lumley, King's College; Frederic Meggy,

Guy's Hospital; Herbert M. Morgan, King's College; Thomas F. Morrish, St Bartholomew's Hospital; Richard Jones Owen, St Bartholomew's Hospital; Daniel Taylor, Bury, Lancashire.

APPOINTMENT.—Dr George Buchanan has been appointed Lecturer on Anatomy at Anderson's University, Glasgow, in room of his late father, Dr M. S. Buchanan.

DR ROBERT LEE has been appointed Examiner in Midwifery at the College of Surgeons, in place of Dr West.

DR WEST has been appointed Examiner in Midwifery at the University of London, in place of Dr. Rigby, resigned.

Dr MURCHISON has resigned the post of Assistant-Physician to King's College Hospital, and has been appointed Pathologist and Lecturer on Morbid Anatomy at the Middlesex Hospital.

ANNIVERSARY OF THE OPENING OF THE SUSSEX LUNATIC ASYLUM, HAYWARD'S HEATH.—On Wednesday, the 25th ult., the anniversary of the opening of the Asylum at Hayward's Heath was observed as a holiday by all the inmates and *employés* of the asylum. In spite of the many difficulties attending the opening of a new asylum and getting it into working order, the whole year has happily passed without one untoward accident. The general health of the patients in the asylum is excellent, and has steadily been improving. The bracing air of Hayward's Heath, and the excellent dietary, have combined to produce this result; and for the rest the unremitting care of Dr Robertson is to be cited as the chief cause of the satisfactory result attained. The numbers in the asylum have been steadily augmenting; and on the day of the anniversary there were 166 males and 205 females; total, 371. This number, we understand, will shortly be further increased by the arrival of the patients belonging to the City of Chichester. The asylum was lately inspected by the Commissioners in Lunacy, who recorded their most favourable opinion of all the arrangements and the management of the patients.

TESTIMONIAL TO A SURGEON.—A circumstance highly honourable to the poor, and to their medical attendant, has lately occurred at Barnsley, a parish in the Cirencester Union, Gloucestershire. Mr. Iles, surgeon, having resigned his appointment, the inhabitants of Barnsley, whose respect he had won by his skilful and assiduous attention to them when sick, presented him with a proof of their gratitude in the form of a handsome ormolu clock, with the following inscription:—"To Albert Iles, Esq., M.R.C.S., from the parishioners of Barnsley, Gloucestershire, in grateful acknowledgment of his unceasing attention, kindness, and liberality to the poor, as Medical Officer of the Cirencester Union. June, 1860."

THE JOHN HUNTER STATUE.—The Medical Profession in this country will learn with satisfaction that Mr South, the President of the Royal College of Surgeons, has received, through Dr Bowditch, of Boston, U.S., 45*l.* as a first instalment from the State of Massachussets towards the statue. Mr Weekes, the eminent sculptor, has already commenced his work.

THE THAMES at the present time (March, 1860) is fuller and cleaner than it has been for some years, mainly owing to the large rain-fall at the end of the last year and during the present year, and to the frequent agitation and consequent increased exposure of the water to the action of the air by the long prevalent gales. Dace and other fish, seldom of late years found below Kew, are now taken as low as Chelsea. The smelt has come up the river in unusual quantities to deposit spawn; and the fishermen from the Medway, the Lee, and other places in the lower part of the river, state that from the present purity of the water they are enabled to bring fish to Billingsgate, in their well-boats, without loss, whereas many were before destroyed by the polluted and comparatively still condition of the water at London.

APOTHECARIES' HALL OF IRELAND. — At the annual meeting of the General Council held, according to Act of Parliament, on Wednesday, August 1, the Governor, Dr. Madden, jun., in the chair, the following officers were elected for the ensuing year:—Christopher Shaw, M.R.C.S.E., Governor; Charles Holmes, M.D., Deputy-Governor; who, with the following Directors, constitute the Court of Examiners:—Dr Betty, Dr Bolland, Mr Collins, Dr Leet, Dr Madden, Dr Madden, jun., Dr McMunn, Dr Mulock, Dr. Nolan, Mr O'Flaherty, Dr Owens, Dr Shee, and Dr. Wyse.

SANITARIUM AT THE CAPE OF GOOD HOPE.—It has been finally resolved by the Indian authorities to institute a sanitarium at the Cape of Good Hope for invalid soldiers from India. This measure has long been debated, but, being resolved on, will be carried into execution without delay. Three hundred sappers are now undergoing a special course of instruction, with a view to fitting them for the nececessary duties in connection with the establishment of this extensive sanitarium. They will very shortly leave for the Cape of Good Hope.

VENTILATION.—A novelty in ventilation may be seen at 142, High Holborn, which appears likely to be beneficial in many cases which have hitherto been beyond the art of man. Unlike ordinary ventilation, which only changes the air of an enclosed place, by admitting the external air, which in populous places is fouled by smoke, dust, and every kind of impurity, this ventilation separates every kind of impurity from the air in its passage through the machine. The change is effected by forcing the air into extended contact with water, or with water containing disinfectants in solution. The process is founded on the natural law, that water has the property of heterogeneous adhesion for all substances that come in contact with it. Common observation and chemical analyis show that the descending rain brings down every kind of impurity of the air, and Mr White has ingeniously imitated this natural process. By means of various machines, he forces the air into contact with water in a manner that will be useful to the cottager in his sick-room, and that provides a luxury and means of health to the denizens of hot climates; for by his process the air can not only be purified, but cooled or warmed at will. The inventor has also pointed out, what has long been a desideratum with sanitary reformers, popular means of testing the amount of impurity of air, and thus the utility of his machine is made a matter of common observation.

PAY IN THE INDIAN ARMY.—In a late number of the 'Medical Times and Gazette,' I noticed an extract from one of my letters. I forward you more details about the pay and allowances of an Assistant-Surgeon of her Majesty's Army when on service in India. I fear it will be stale news, though. To give you a better idea I will contrast the pay of an Assistant-Surgeon of her Majesty's Army serving in India, with the pay of an Assistant-Surgeon of her Majesty's Indian Army. The following is the bill you have to send to the Paymaster of the Queen's Troops at the end of the month; and then you wait eight or ten days while your little account is being audited and pulled about by a lot of indolent natives before you receive the cash in new rupees. To get that money it costs me gurree or carriage hire, two rupees, sometimes four or even eight. Pay at a central station:—Pay and Indian allowance, 145 rupees 12 annas, or 14*l.* 10s. and a fraction per month; extra batta, none; regimental house-rent, 30 rupees, or 3*l.*; tentage, 50 rupees, or 5*l.*; palkee allowance, 30 rupees, or 3*l.*; total, 255 rupees 12 annas, or 25*l.* 10s. In England I drew 16*l.* 10s. for thirty days. A smaller sum than the above, to all appearance, yet really it was greater. I lived easier on English pay than I do on the Indian rupees, and you know I am prudent. My expenses are, per month:—Servants, including washing and everything relating to servants, 29 rupees; messing, 62 rupees; beer, &c. (indispensable), 21 rupees; moonshee, 30 rupees: total, 142 rupees. This list does not include horse expenses. Horse exercise, I may add, is absolutely necessary, as it helps to lessen the intensity of constipation, from which all Anglo-Indians suffer more or less. I have not included either price of quarters, cab hire, or extras (such as ice, brandy, dinners, tailors, who are awfully expensive here), and other things as necessary as the above. At the end of the month I can assure you I have very few rupees to spare. I forgot to mention, too, that you must also furnish your rooms, and when you are ordered off, sell at a loss. You must put up with being robbed right and left, and with your washerman, who also pounds your linen to rags in a fortnight. All these little things are never thought of by our Indian Nabobs, or else would their hearts have softened towards the hard-used, over-worked Assistant-Surgeon of her Majesty's Army. The pay of a friend of mine, an Assistant-Surgeon of the Indian Army, is 421 rupees a month. We ought, and shall, be better paid, for we run risks from diseases which kill more than the sword; and we have the same chance of carrying about a congested liver as have the servants of the Indian Government. Shameful to say, we are in the Queen's country and yet her noble Warrant is not recognised. I tell these things so that you may not, if you enter the Queen's Army, apply for Indian service as I did, with the idea that I should be better paid here than elsewhere. No one would come here for glory now, for the mutiny is over. If you wish to serve in India, serve in the Indian Army.—Extract from Letter of an Assistant-Surgeon of her Majesty's Army, May 20, in 'Medical Times and Gazette.'

APPOINTMENTS FOR THE WEEK.

Wednesday, August 8.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, August 9.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2½ p.m.

LONDON HOME.—2 p.m.

Friday, August 10.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, August 11.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, August 13.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, August 14.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

J. C. H.—Certainly.

CHIRURGUS.—Mr Fergusson and Mr Syme are, we believe, the only great surgeons who have frankly expressed their non-conformity with the general opinion about the superior advantages of the metallic suture. Our opinion is that there has been a great deal of exaggeration about the evils of the silk and the advantages of metal; and we are, at the same time, certain that the silk threads are much more easily applied in difficult situations. It is a satisfaction to find a man like Mr Fergusson giving his candid opinion, uninfluenced by fashion.

L.S.A.—The Bill will not affect your position.

A LICENTIATE.—We have done our duty; the responsibility of self-defence necessarily devolves on those whose interests are attacked. The present Bill, however, is not so important as supposed.

Mr H. JONES.—1st. Yes.—2nd. Yes.

M.R.C.S.—1st. No.—2nd. Undercliff, Isle of Wight, during the winter and spring would be eminently suitable.—3rd. There would be no advantage in going further south.

ALPHA.—We think your complaint justified by the facts.—2nd. There is no legal remedy.

Mr HODGES is thanked.

Dr H. T.—The publisher will attend to your request.

PATER.—Under the regulations now in force.

A SUBSCRIBER.—Yes; by examination.

MEDICUS (Brighton.)—The best remedy for psoriasis in its acute stage, that we know, is liq. potassæ, from forty minims to a drachm, diluted in half a pint of milk, three times a day. It is important to observe the proportions. Small doses are of very little use. Afterwards arsenic may be administered.

PETER PINDAR. — Communication received; but poetry being unsuitable to our columns, we decline the verses.

A SUBSCRIBER TO THE ROYAL MEDICAL BENEVOLENT COLLEGE.—The fault does not lie with us, if fault there be. We trust that Mrs Jenner will be admitted.

Dr HILL.—Received.

AN IRISH SURGEON.—Received and inserted.

Mr FALCON (Fulneck.)—Communication received and inserted.

Dr TUCKER.—Received; your request shall be attended to.

Letters received from Dr Smart, W. Graham, A. Furlong, Dr Paley, Dr Bullocke, R. B. Moore, W. H. Johnson, W. Batten.

ON THE TREATMENT OF GONORRHŒA WITHOUT SPECIFICS.

By J. L. MILTON.

(Continued from p. 88.)

4. *Tendency to Inflammation of the Lacunæ of the Urethra.*—However hazardous the statement may seem that inflammation of the lacunæ rarely—perhaps never—ensues under the use of the treatment recommended for simple gonorrhœa, provided this has had time to act before the lacunæ are involved, I believe I am warranted in making it; but, whether it ensues or not, the treatment of the parent disorders may be safely pursued, even though the previous experience of the patient is that this complication will follow.

A surgeon, at that time a student, placed himself under the care of Sir Astley Cooper for gonorrhœa. The great surgeon ordered him an injection of nitrate of silver, five grains to an ounce. The inflammation and pain, however, became so unmanageable that he was soon laid up with orchitis and abscess of the lacunæ. The latter burst externally, leaving a fistulous opening which healed in a few weeks, and a gleet which lasted ten months. Subsequently he had a second attack, which healed in four months by means of copaiba and injections. This time the lacunæ suppurated. He contracted a third gonorrhœa, and treated it himself with small doses of copaiba and cubebs, which purged and nauseated him so much that he was quite prostrated. Dyspepsia and total loss of appetite came on, making him so irritable and weak that he could not mount his horse or attend properly to business. Within a fortnight, three of the lacunæ had run into suppuration, and one had burst externally. He then consulted me. A mild saline aperient with full doses of morphia at night was ordered, along with sulphate of zinc injections. Subsequently quinine and purgatives were given, and blue ointment was directed to be rubbed over the lacunæ. He speedily improved; no more lacunæ suppurated—the discharge rapidly subsided, and in a few weeks gave way entirely.

5. *Excessive Irritability of the Bladder and Rectum.*—Sudden and almost irresistible irritability occurs at times in very healthy persons, often when the gonorrhœa is yielding to the influence of medicines; but there is also an extreme and rare form which is encountered in delicate persons, and appears to arise from the gonorrhœal inflammation extending back to the bladder within the first few days of its existence. It is sometimes accompanied by a strong tendency to evacuate the bowels on administering a urethral injection.

I regret to say that, notwithstanding all my attempts, I have failed to discover any remedy on which we can rely in either form of irritable bladder. I have tried every means recommended in standard works, along with most of our sedatives and antispasmodics—such as sumbul, chloroform, &c.—with no better result; and now, after accurately noting every case that came within my observation during the last ten years, I am obliged to confess that in at least half of these, medicines in safe doses produced no effect, and in the other half it was often doubtful if improvement was not rather a concomitant than a result. In the form, however, to which I allude, and which I have not often seen, I found the ordinary remedies so injurious, that I soon abandoned them in favour of tonics and mild sedatives—an antacid purgative, such as a dose of Henry's magnesia or the effervescing citrate, and the steady use of injections. The following history will, I hope, exemplify this class of cases better than any formal description:—

A gentleman engaged in speculation of a very hazardous nature, and subject in consequence to all the variations between the extremes of excitement and depression, consulted me respecting a gonorrhœa which he had just contracted. As he seemed very irritable and nervous, I inquired into his history, and found that, after having been long in indifferent health, he had two years before been attacked with influenza, for which he placed himself under the care of a well-known physician.

The disorder slowly gave way, but he had never regained his flesh and strength; his digestion was impaired, his appetite capricious—bowels often costive, urine loaded with phosphates and mucus, tongue coated and marked by the teeth. He was haunted by a feeling that he was growing smaller, which, he said, in spite of its absurdity he could not shake off. The discharge from the urethra was thin, yellow, and profuse, much like that occasionally seen, without any very manifest cause, in elderly men. There was no particular uneasiness about the parts of generation; no pain in making water, chordee, or swelling of the prepuce. The discharge had appeared only two days previously.

A mild saline aperient was ordered, and, as the patient was very timid, only a weak injection was employed. In a few days the irritability of the bladder became so excessive, that the injection was instantly thrown out again with a little urine, and the patient had to make water three times in the first half-hour after. This state continued to a certain extent up to a late hour in the evening. He was ordered meat and a glass of port daily—quinine and sedatives were given, and as it was found that the occasional use of brisk cathartics induced much less irritability of the bladder and rectum than the mild aperient had done, they were substituted. Injections of nitrate of silver, however, were principally relied on to remove the discharge.

The first effect of these was to increase the irritability of the bladder for an hour or two after using them, when it quickly ceased, and did not return till the injection was repeated the next day. Having syringed out the anterior part of the urethra, the tube of the long syringe was passed down, and, when withdrawn, pus was found adhering to its point. This symptom, coupled with the extreme tenderness of the whole of the urethra, led me to believe that the gonorrhœal inflammation had extended backwards to the neck of the bladder, if not also to the cavity of this viscus. The long syringe was substituted, and the injection was gradually raised to the strength of ten grains to an ounce; an amount I have always found necessary whenever it was requisite to apply injections low down. This alteration had the desired effect, the discharge diminishing steadily, though it did not entirely disappear for six weeks. The irritability of the bladder grew gradually less, but to the very last the patient was always compelled to sit down immediately after an injection, and hence, as they were continued occasionally for some weeks after, it may be assumed that this irritability endured, in all, full ten weeks in a rather severe form. There was no relapse—the patient gained flesh and strength under the use of quinine, and married soon after.

Excessive Irritability of the Rectum seems principally due to the sudden and irregular distension of the urethra by the injection. I injected a gentleman with solution of nitrate of silver for a gleet which had been treated with chloride of zinc injection and copaiba; he was compelled to make a precipitate retreat to the water-closet. The next day I made the injection quite weak, although the first had occasioned no great pain. The irritability of the rectum was still as great: I then passed down a short sheath and stilet, and introduced a strip of calico soaked in a strong solution of nitrate of silver. This did not induce any irritability of the rectum, and four applications removed the discharge. It came back a little, and he never summoned up resolution again, saying that for a mere drop of discharge it was not worth the trouble.

5. *Perinæal Abscess.*—Of gonorrhœa accompanied by this complication I cannot give so favourable an account, not having found it so amenable to treatment as might have been expected. Fortunately enough, it is rather rare.

It is laid down as a rule of treatment, that leeches, antimony, calomel, and black draught should be exhibited for this affection. Those who have succeeded with these remedies in checking the progress of perinæal abscess, have had better fortune than has fallen to my share, as they have never appeared to me to exert any material influence over its course.

The only remedy from which I have ever found benefit arise, is the potassio-tartrate of antimony, in large doses, aided by the application of water at a very scalding heat to the perinæum, and sometimes the free application of the nitrate of silver to the surface.

24 Castle street, St Martin's-le-Grand.

(To be continued.)

CLINICAL REPORTS.

Rupture of the Urethra, with Hæmorrhage and "Retention," from Stricture—how should they be treated?—Mr Clark.

Two cases recently under treatment in St Thomas's Hospital indicate how useful it is occasionally to try cautious medical temporising measures previous to the adoption of hazardous and heroic cutting surgical operations: indeed, there are few thoughtful persons who have been a series of years observing operations in our larger hospital, especially operations on the urinary organs, amputations, &c., that would recommend unnecessary cutting of any kind.

Case I.—One case was that so frequently seen in our large hospitals—rupture of the perineum in a young man, who in this instance fell violently with his perineum in contact with the sharp edge of a chair-back straddle-wise, lacerating the tissues of the part, and causing profuse hæmorrhage from the urethra. This class of case, though seen so frequently, is yet well calculated to test a surgeon's skill, whether he would try temporising means, or have recourse to something more showy and brilliant. Mr Clark, called to see the lad, at once obtained a large full-sized catheter, which he passed into the urethra as a sort of "tampon" without difficulty, and he ordered a bag of ice to be applied to the perineum. The urine drawn off was clear, proving that the blood was derived from the urethra, and not from any injury to the neck of the bladder. Mr Clark observed at the time, that it was important to pass a catheter before the patient made water; and his reason for selecting a full-sized instrument with a blunt point was, that he was thus less likely to meet with obstruction or to do mischief than with a small one: moreover, it would effectually fill the urethra, as just said, and prevent the urine from finding its way along the side of it. The success of this plan was quite satisfactory.

Case II.—In a case of retention, the patient had not been able to micturate for several hours. His bladder, as felt over the pubes, was very much distended. The man said that, at the best of times, his water was "twisted like a cork-screw," and he felt there was something incontrovertibly wrong in the passage: attempts to pass a catheter out of doors, before he came to hospital, had failed. Warm bath and opium (in which, we may say, "en passant," Mr Skey and Mr Erichsen also have very great faith) did not seem to act as quickly as expected, and it was in contemplation to puncture the bladder by the rectum, when Mr Clark tried a little expedient or "knack" which he has frequently seen succeed. This is, to introduce a firm bougie as far as it will go, and while passing it through or against the stricture, directing the patient to strain as if making an effort to pass water, and then suddenly draw out the instrument. The opium, we believe, assists this manœuvre also, or chloroform assists it. A small stream of water followed the experiment, and after a short time the man had passed six or eight ounces. He was then ordered an active saline purge to take the strain off the kidneys, and on the following morning the man had passed abundance of water, and has had no retention since.

This man was saved a disgusting and not at all a safe operation—perforation of his bladder through the rectum. He now passes water fairly, but still even a small catheter cannot be got on into the bladder: the urethra, as the surgeons at St Thomas's believe, is most probably quite tortuous by the irregular deposit of lymph at different sides or points of its track in the submucous cellular tissue. It is not impossible that in this little expedient or "knack" of passing a bougie, and directing the man to strain as if bringing the bladder and urethra into "consensus" for micturition, the delicate muscular fibres and detensor muscles are all brought into action.

How is Hæmatocele to be diagnosticated from Extra-Uterine Gestation? or Extra-Uterine Gestation from Fibrous Tumour of the Uterus?—Dr Jones.

Hæmatocele in the female is a new disease, liable to be mistaken for what we described (*ante*, page 78) last week as extra-uterine gestation. As this is now "all the talk" of the hospitals, we believe it will make the subject more complete to refer to this and a case recently at the Metropolitan Free Hospital. Some cases of extra-uterine gestation, like that given by us last week in the practice of Dr Ramsbotham, might be mistaken for hæmatocele, or another different disease, fibrous tumour of the uterus; so that we deem it important to give the particulars of the diagnosis in such cases: indeed, this case of "tumour," thought to be extra-uterine gestation, has been for some time under care at the Metropolitan Free Hospital, but turns out to be a different case altogether. Fibrous tumours of the uterus, perhaps, if well marked, would be recognised by their history, their consistent hardness, their attachments, &c.; hæmatocele, by growing more quickly, being less moveable, and the like; extra-uterine pregnancy, by the usual signs of pregnancy, with the ordinary alterations in the mammæ and cervix and body of the uterus. This all seems clear enough; still we are not so sure that the signs and tokens so easily laid down in special treatises are so easily remembered, or ever at all taught by our "pures,"—or that even the boasted *tactus eruditus* of our most solemn pure surgeons or general physicians, who join in a useless crusade against obstetricism and specialism, (our Baker-Browns and Simpsons,) would not be, and in point of fact is not often at fault, (they will excuse us,) in these odd things taught us by the special hospitals and specialists.

Hæmatocele in the female has been noticed as a very rare, if not mythical affection, by Dr West, as also by Professor Simpson; but Voisin gives twenty-seven cases. It has been recently imagined as seen also in Dublin; but, except in the out-patients' department of our larger hospitals or in private practice, we think it is not likely to come under notice in our usual visits to hospitals. Dr West with much assiduity got together eight problematical cases. It is sometimes very sudden in its appearance, and a patient may even die before she can be carried to hospital; yet it is a disease, like extra-uterine gestation, that may be met at any moment in general practice.

But what is the disease? some one asks. The name is perhaps not a fortunate one. The disease as originally noticed and its history perfected amongst the specialists of France, and now known as "retro-uterine hæmatocele," consists of certain hæmorrhagic tumours of a fluctuating nature, situated between the uterus and rectum; this true hæmactocle, so to call it with the specialists, existing essentially, as it is now found to do, as an accident or error of menstruation, the blood lying almost always in the peritoneal sac between the uterus and rectum. Another form of the disease, not so specific, exists where blood is extravasated into the cellular tissue behind the uterus and outside the peritoneum, of the nature of thrombus rather than as encysted blood from menstrual disturbance. Or, again, in a third form, blood may collect in the folds of the broad ligaments, caused by any unusual violence of the parts. Here it is, at a glance, quite obvious that in the first variety only are the active organs engaged in menstruation—the ovary, Fallopian tube, or uterus at all implicated. The disease in the woman is usually caused by some violence during coitus or menstruation; as, for instance, with a violent drunken man; in this particular agreeing in some measure with the chief cause of extra-uterine gestation referred to by us previously (p. 78), viz. fright on the part of the woman also at this time: this, of course, is easily understood. The mischief generally in uterine hæmatocele, but not always, dates from a menstrual period; nor is it difficult to understand how this comes about, as, in addition to the organs just named as so much engaged by reflex action or emotion, or congested, we have also the entire uterine system in a congested state, as well as the hæmorrhoidal vessels, &c. The blood in the simpler forms of the disease is found to be extravasated and coagulated in masses, and is probably absorbed; but in the other more complicated shape in which the disease appears, the blood becomes altered, suppuration takes place, and the contents of the cyst, as in extra-uterine gestation already referred to, escape externally; nay, it has been found that the hæmorrhage may be active in some cases, though passive in others. As to the causes of the disease, diminution or alteration of the fibrin in the blood is thought to be a predisposing cause. A patient with measles has been known, for instance, to die immediately after the commencement of menstruation from a hæmatocele which originated in the left Fallopian tube; another patient in slight small-pox, also has been similarly affected from the same cause.

This disease, it is well to remember, is not associated with amenorrhœa, but rather with the conditions already referred to of emotional excitement, or a condition of plethora with abundant and habitual menstrual flow, usually light red with clots. There is also pain, and very often pain is felt at the time already referred to, when the woman suffers violence. The disease is very likely to be met with in manufacturing districts, where women mix in a rough manner and drink in company with men, and it has been more than once mistaken for poisoning!

A very essential difference is found to exist between what is known as the encysted and the non-encysted forms of hæmatocele. If the extravasation be slow, it becomes encysted and surrounded on all sides by lymphy adhesions; but if rapid and abundant, the blood spreads over a large surface of the peritoneum, and if the patient does not sink from the loss of blood, death is unfortunately sure to result from the extensive peritonitis set up: the blood from the uterine cavity, if it should reach to or remain in that part, is also mixed up with a very irritating mucus. "Hardly have some drops of blood penetrated into the serous cavity," says the chief authority on this disease, "than it inflames. This results in speedily establishing adhesions between all the pelvic organs, or rather between their peritoneal coverings. The coils of intestines are pushed upwards; the collection of blood encysts rapidly, by means of the inflammation of the serous membrane and formation of cellular adhesions." In the non-encysted hæmatocele the disease is so sudden and alarming, that poisoning will probably be suspected. The symptoms are intense abdominal pain, with intense distress and agitation: the poor woman is anæmic from loss of blood; the belly becomes hard and tender; hiccup and vomiting are sometimes present; syncope follows, and death in a few hours. A tumour is felt above the pubes, on the right oftener than the left side; or where the disease is more persistent, examined through the vagina, it is felt pushing forward the cervix uteri, flattening the rectum, and stretching the walls of the vagina, it fills the inferior opening of the pelvis; it may become as large as a child's head, and rarely increases in size after its first formation; the serum of the blood in the hæmatocele is absorbed, but the coagulum remains. When menstruation is established again, it is followed by a diminution of the tumour, and it may even all go away in three or four months. In twenty-seven cases, six emptied themselves by the rectum, three by the vagina, and four burst into the peritoneum.

So far we have said what the disease at the Metropolitan Free Hospital is found NOT to be, though in some measure not unlike hæmatocele. It is useful, sometimes, thus to have a peg on which to hang something of the thin tissue, the web and woof of diagnosis, the hair-splittings of the talk of hospitals, especially as we ever and again, notwithstanding the utmost industry, come on men who will misrepresent us.(*a*) In our figures we always strive to be rigid and correct; though many other portions of our clinical reports we wish to be of the nature of diagrams, giving the rough, broad outlines of hospital practice, which are many times more useful than dry, unreadable details of second year's students, as to every-day common cases, mirrored for us week after week. Diagrams are like statistics, finger-posts in the cross roads of medical and surgical science, and many cases like the following are mere diagrams.

Mrs W., aged twenty-nine, applied last June with a history of what would be called "spurious pregnancy," from January, 1859, to October of that year, when, although a midwife had been engaged, and everything ready for her confinement, a consulting accoucheur having been sent for, the case was declared to be an abdominal tumour, perhaps fibrous, but not pregnancy. This is a case which we might spread over an entire page. Admitted to hospital eighteen months after the suspension of menstruation, the woman's abdomen was about as large as it would be in the seventh month of pregnancy; it is, in fact, occupied by a large firm mass, which may or may not be an extra-uterine gestation, hæmatocele, or pregnancy. The breasts are developed and contain milk, the areolæ are dark; the fact that the woman has had no hæmorrhage or injury militated against extra-uterine gestation, and as the os uteri is felt high up, the cervix short, and a flexible sound may be introduced for the length of four inches, and as the tumour is easily felt and peculiarly hard, it is now deemed to be a fibrous growth. For some time, however, it had the character of "hæmatocele," a new disease as far as our London hospitals are concerned, and of which and extra-uterine gestation we have deemed it right to give the preceding description.

(*a*) Of such is Dr Eben Watson, a young surgeon, a "pure" who deems it *infra dig.* to look into the specialism of Mr Baker-Brown's vesico-vaginal fistulæ cases, of which we have in this place reported thirty cases—about twice as many as all our larger hospitals or Dr Eben Watson's picked milder cases put together.

THE SPIRIT OF THE PERIODICALS.

The 'Dublin Quarterly Journal' opens with an article on the *Natural Constants of the Urine of Man*, by the Rev. Samuel Haughton. This reverend gentleman appears to follow out his physiological inquiries with remarkable zeal and acuteness. We are unable to give an abstract of this very elaborate paper; but we may remark that some curious conclusions are stated: for example, the Author says that it requires 297·7 grains of urea to keep 150lb. of man alive for twenty-four hours, and that the actual value of vital work this represents is calculated at 769·45 tons lifted one foot. He says:

"This enormous force is requisite to keep 150lb. of man living during twenty-four hours, and yet it is not all that is required; for, in addition, there is the *Opus calorificum*, or work necessary to keep the skin at a constant temperature of 90° F. The amount of this latter work will vary with climate and season, and appears to depend altogether on the excretion of carbonic acid, and not on that of urea."

In another place he says that the vital force required to keep "a man of any weight alive for twenty-four hours, is capable of lifting his body through 2·18 miles in the same time."

Some observations then are made on the vital force expended on mental work; we can only, however, append the conclusions arrived at:

"1. The quantity of urea passed per day by men in health varies with their food and occupation, the latter being the principal cause, and regulating the other.

"2. Men employed only in manual or routine bodily labour are sufficiently well fed on vegetable diet, and discharge on an average 400 grs. of urea per day, of which 300 grs. are spent in vital, and 100 grs. in mechanical work. This conclusion is in conformity with the experience of the mass of mankind employed in manual labour in all ages and countries.

"3. When the work is of a higher order, a better quality of food must be supplied, sufficient to allow of a discharge of 533 grs. per day of urea, of which 300 grs., as before, are spent in vital work, and 233 grs. in mental work and the mechanical work necessary to keep the body in health.

"4. The quantity of urea discharged per day

varies also with the weight of the individual, which influences the vital and mental work.

"5. The habits, weight, and occupation of the individual enable us to account for a range of the diurnal quantity of urea, varying from 300 to 630 grs. per day; and this discharge may be confidently predicted, when the habits and weight are known.

"When, in any case, the discharge of urea exceeds that calculable from the preceding data, it must be attributed to ill-health, and most generally to that most fatal of all diseases to which man is liable—anxiety of mind—a vague and unscientific expression, which, however, denotes a most real disease.

"This fact alone would render the preceding investigation of importance to the physician, as it enables him, in a given case, to pronounce whether there is an excess of urea or not, and a consequent waste of the system. I have shown that the mere quantity will not decide this question, as from 300 to 630 grs. may be discharged by persons in perfect health, according to their peculiar work and physical conditions.

Note.—The following Table has been published by Dr William D. Moore, of this city, since the first part of my paper was read, in the 'Dublin Medical Press' of the 27th July, 1859, and reached me too late for insertion in my own paper.

Quantity of Urea eliminated during Twenty-four Hours, according to Dr Warnecke.

		Grms.	Grs.
1	Adult man (mixed diet) . .	33·7	520
2	,, (vegetable diet)	25·3	390
3	Adult woman (mixed diet) .	26·8	413
4	,, (vegetable diet)	20·1	310
5	Boy (seventeen years) . . .	19·8	305
6	Girl (,, ,,) . . .	18·0	277

"These results, which are the averages of seven experiments on each individual, are perfectly in accordance with my own results, contained in Tables A and B."

We extract the following article on *Diabetes Mellitus* from the 'Journal of Practical Medicine and Surgery:'

"In Saint-Antoine ward, we noticed a woman, aged forty-six, who, eight months ago, observed on her linen and upon her shoes whitish stains, in which Dr Béhier, a physician of the hospitals of Paris, detected the presence of diabetic sugar. In this case, the disease had originated twenty-two months previously. At that period the patient experienced a burning thirst, particularly at night. She was in the habit of drinking as much as fifteen quarts of water in the course of the day, and a quantity of urine, at least equivalent, was passed in the twenty-four hours; a fact illustrative of Thénard's remark that in diabetes the quantity of urine secreted by the kidneys is generally superior to that of the fluids ingested into the stomach. The patient moreover had lost all taste for food, as it most commonly happens, although the contrary has been asserted. Under the influence of the treatment instituted by M. Béhier, the appetite had improved, and she was in other respects progressing satisfactorily, when she became affected with cough, expectoration of greyish sputa, oppression, and precordial anguish extending to the throat, but without the propagation of pain to the left arm, peculiar to angina pectoris. On auscultation, the signs of incipient pulmonary tuberculosis were detected, a complication frequently met with in diabetes. The thoracic symptoms, for which the patient had been admitted into the Hôtel-Dieu, speedily yielded to appropriate measures, diabetes remaining to be contended with, and towards this complaint the attention of the Professor was exclusively directed.

"Other signs, in addition to excessive thirst and polyuria, point to the probable existence of diabetes mellitus. We may mention, for instance, the acid condition of the salivary secretion, a circumstance noticed by M. Mialhe, and the significance of which was fully confirmed in the present instance. On one occasion, by this single symptom, M. Mialhe was led to the discovery of diabetes in a person who was entirely ignorant of his condition. The best guide of diagnosis, however, is the examination of the urine. In health, this secretion presents a specific gravity varying between 1017 and 1020; and when its weight is found to exceed 1040, the presence of glucose may be strongly suspected. In the case alluded to above, the urinometer marked 1033·34. As to the actual detection of glucose, it is most commonly effected with Bareswill's solution, a very delicate and satisfactory test, when added to the urine in the proportion of 2 to 1, and when the absence of albumen has previously been ascertained. In his patient, M. Aran found 9½ drachms of sugar for 32 ounces of urine.

"The functional disturbances arising from diabetes mellitus are well known, although both physicians and chemists remain in doubt as to their causes and seat. M. Bouchardat considers diabetes to originate in a morbid change in the digestion and assimilation of farinaceous substances, while M. Bernard refers it to a peculiar lesion of the nervous system. M. Alvaro Reynoso ascribes the disease to the imperfect combustion of glucose, from improper accomplishment of the respiratory functions; in M. Mialhe's opinion, diabetes is caused by the insufficiently alkaline condition of the fluids of the system, hence inadequate assimilation of glucose. Whatever be the respective value of these theories, M. Aran conceives that both M. Bouchardat and M. Mialhe have rendered signal service to the treatment of the malady, the former in pointing out the injurious effects of farinaceous nutriment, the latter in recommending the use of alkaline remedies. The history of the patient who suggested the present remarks is confirmative of M. Bouchardat's theory. She chiefly fed on farinaceous substances; after consulting M. Béhier, she restricted herself almost entirely to azotized food, and under the influence of this change the amount of urine excreted fell from 15 to 11 quarts, and subsequently after a spontaneous attack of diarrhœa, by which this quantity was further reduced to 6 and even to 5 quarts in the day; she also derived considerable benefit from repeated doses of aperient medicine, and after four months' treatment she seemed restored to health. She then, however, returned to her previous regimen, and diabetes has reappeared in consequence of indulgence in the forbidden articles of diet.

"Diabetes has ceased to be a serious malady. For the last twenty years, M. Mialhe has attended patients affected with glucosuria, who may still continue to live long. It is, however, a cause of emaciation. M. Aran's patient, while in health, weighed a little above 15 st., and now she weighs but 9½ st. On a former occasion, when descanting on the utility of the ophthalmoscope, we mentioned the disturbances of vision to which diabetes gives rise (Art. 5329). It is therefore a complaint which should be treated, and although M. Aran is inclined to think it is not one which can be radically cured, still he doubts not that diabetic subjects, provided their constitution has not been too deeply injured, may, by proper care, ward off its fatal tendencies.

"For this purpose, the action of the skin must be solicited by violent exercise, vapour baths, and flannel garments. The food should be highly azotized, and bicarbonate of soda be exhibited in accordance with M. Mialhe's views. M. Aran does not venture on any rational explanation of the *modus operandi* of this system of treatment: the chemical data on which it rests may be correct or incorrect, but the results are manifest, and it is not without reason that Vichy is crowded with patients afflicted with diabetes. In the case of the patient lying at present in the wards of the Hôtel-Dieu, the daily prescription is the following:

"One ounce of bicarbonate of soda to be taken in the drinks.

"Claret 16 ounces.

"Bark-wine, 3½ ounces.

"Full diet of meat, equivalent to about 24 or 26 ounces of animal food.

"A vapour bath, followed by cold affusion.

"Spa-water at meals.

"Four quarts of the usual diet-drink."

The 'Lancet' opens with a continuation of Mr Hilton's Lectures on *Pain and Rest*. This is followed by a report of a *Case of Abscess of Bone* under the care of Mr Quain. We quote Mr Quain's remarks upon the case:

"Mr Quain observed, that the first point—the main point—is in this, as in many other cases, the formation of an accurate diagnosis. To establish it here the chief reliance must be placed on the character of the pain and the swelling. As regards the pain, it is often difficult, in examples of local suffering, to determine if the suffering is owing to an appreciable local disease or not; and the presence of local disease—say of bone—being decided on, it is essential to determine its nature, for on the decision arrived at must depend the treatment.

"Very intense pain is found to exist without appreciable local disease; for instance, I was asked by a surgeon connected with a dispensary in this neighbourhood, to see one of his patients who had suffered for a considerable time from pain—excruciating pain—in one of the knees. I found the knee and the hip free from evidence of organic change. It was an example of local nerve-pain. Subsequently, the limb was amputated at the thigh by an eminent surgeon, who took a different view of the cause of the suffering. But the joint was sound, and the operation only served the purpose of proving again, and beyond all question, what was well known before, that local pain by itself is not a proof of appreciable local disease.

"The reverse of this, too, happens:—*e. g.*, I know a person who complained of a tingling in the fingers of one hand, and inability to use it. He had been treated for more than a year, and had taken a large quantity of medicine, in the belief that the tingling of the nerves arose from an affection of the brain. Yet it was wholly the result of a swelling in the wrist, of which he was almost unconscious, and to which he had not called the attention of the physician under whose care he had been. The pain and disability in the fingers were removed by the removal of the disease in the wrist.

"Examples of pain occasioned by disease at a distance from the seat of distress are of every-day occurrence at the hospital. You will remember a man suffering much in the wards just now, who complains exclusively of the knee, which is free from disease, the real malady being at the hip. Such cases must be familiar to you. But one case, from its singularity, may be dwelt on for a moment, as affording a clear illustration of this kind of suffering. A female patient complained of intense pain under the balls of the toes, across the foot. She had long been under treatment at various institutions; had taken much medicine, including arsenic, and she stated that she derived relief from that drug, and only from it. The relief, however, was only transient. Suspecting, from the appearance of this person, that there might be a local cause,—perhaps from pressure on some part of the nerve, at the end of whose branches the pain was felt,—I made a closer examination along the limb, and found a small swelling on the back of the thigh, beneath the hamstring muscles. Pressure upon it aggravated the pain of the foot. I removed a bone-like tumour from the interior of the internal popliteal nerve, and the long suffering in the foot was thenceforward at an end.

"Pain, then, may exist without appreciable local disease at the part where it is felt or elsewhere; it may result from disease, more or less remote from the seat of suffering; and it occurs (this is most common) in close connection with actual disease. Of this last, examples are constantly before us in the hospital in cases of disease of the bone.

"I have said enough to show the importance of a close inquiry into the cause of that important symptom, *pain*, in order to determine what it really betokens. To the indication it afforded in the case under observation we shall return presently. Meanwhile a few remarks on the *swelling*. We have to inquire if that swelling was a certain indication that active interference was necessary. Here, too, as in every other matter of practice, cases previously observed will help us by illustration or contrast. Brief references will be enough for our present object. A man, aged forty, felt in going down stairs, and afterwards in walking anywhere, a good deal of pain in the upper part of one leg, and he fell lame. On examination, the tibia was found to be enlarged above the shaft, and the enlargement was accompanied by a change of shape. The bone was filled out on each side below its head, so as to be uniformly rounded, instead of being angular, as it normally is. The contrast between the limbs was very well marked.

The pain, though severe during exercise, was diminished, but did not cease, during rest.

"With improvement of health, which had been somewhat impaired, this gentleman was relieved of his local pain, and now, after the lapse of twelve years, he is able to take any active exercise on foot, without suffering; he *feels no pain*, but the *swelling continues undiminished.*

"That, like the case the history of which I have read to you, was an example of swelling of the bone confined to the upper end, and accompanied with pain. We are seldom without examples of enlargement of the shaft of the tibia, attended with more or less suffering from pain. The enlargement or hypertrophy in these cases commonly affects the thickness of the bone only, but occasionally its length as well. The worst cases of thickening of the bone that I have seen have been connected with syphilitic taint of the system. In such cases, the shaft is the part chiefly affected.

"Let us turn now to the pain and the swelling in the case recited, as the guides in forming the diagnosis. First, as regards the pain. After careful examination, it was plain that the pain did not arise from any general or constitutional state of the patient. He had never been subject to any local pain without a local disease. He was a laborious and healthy man, not one of the class of persons in whom pain without a local cause is found to arise. There was not, moreover, any disease in the limb, except in the place referred to, to account for the pain, and no other conclusion seemed possible but that the pain arose from the swelling at the point at which it was felt.

"The character of the pain was not without its importance. The patient described the pain as like that of a 'gathered finger;' it was such, in fact, as might be expected when pus was being formed.

"Again, as to the swelling, it was confined to the end of the bone, and it is at that part of the bone that collections of pus have been met with. It had not lasted for a great length of time, and there was tenderness to the touch over it.

"These were the circumstances which led to the conclusion that the patient's sufferings were owing to abscess in the cancellated part of the bone, and to the practice pursued."

Dr Sisson of Cheltenham contributes a paper on *The Value of Tonics in Asthenic Dropsy.* As there are some points of interest in the case, we quote it.

"Whilst Dr Handfield Jones's case of ascites, in 'The Lancet' of the 7th ult., shows that some forms of dropsy are curable by tonics, and unaffected by diuretics, the following points out the fact, that others, though benefited by drugs of the latter description, require the former to complete a cure:

"Mrs ——, aged forty-five, has been ailing more or less for the last ten years, during which time she has been frequently under treatment with only temporary benefit. For the last three years she has had swellings of the face, abdomen, and legs. Catamenia have appeared only once in that time, and then in excess. Has had an eruption on the skin, unaffected by treatment. For the last two years or more, she has lived on slops, forced down without appetite. Has had frequent vomitings, with diarrhœa, blood being often passed with the stools.

"May 16th.—Found her in bed, presenting the following symptoms:—Face much bloated; abdomen very protuberant; body generally anasarcous, with large dropsical swellings in depending parts; much emaciated in parts not concealed by effusion; patches of eczema on back of hands, feet, and front of legs; great dyspnœa; horizontal position intolerable; incessant cough, expectoration thin and frothy; complains of great pain in the chest; on percussion, marked dulness on the right side, over lower half of lungs posteriorly and anteriorly; loud crepitations; mucous râles; pulse 100, feeble; urine turbid, scanty, of dark-brown colour, not coagulable by heat and nitric acid; stools liquid, dark, and offensive. To apply turpentine stupes to chest; chloride of mercury, three grains; powdered rhubarb, ten grains. To be followed by an aperient draught.

"17th.—Ordered bitartrate of potass, one scruple; vinegar of squills, spirit of nitrous ether, of each ten minims; compound decoction of scoparium, two ounces, thrice a day; beef-tea, and half an ounce of brandy every four hours.

"The patient improved most satisfactorily up to the 25th, when her husband summoned me in haste, stating that his wife was dying. I found her gasping for breath; pulse at the wrist scarcely perceptible; had complained of great pain in the chest. Apply turpentine stupes to the chest; hot bottles to the feet, and give one drachm of brandy. Nutrients more frequently; continue diuretic mixture and brandy.

"29th.—The patient was delirious last night; got out of bed, and went into the adjoining room. This morning she is nervous and fidgety. Pulse 120, weak. Half an ounce of brandy every two hours; continue diuretic; twenty minims of tincture of opium at bedtime.

"30th.—Slept well last night; much improved; dropsy disappearing, except in face and legs; urine much increased, clear. She called my attention to a swelling in the right iliac region, for which she had been previously under treatment. Now that the ascites was removed, I perceived a tumour in this situation, of the size of a large fist; painful; movable; outline distinct; fluctuation perceptible. As vaginal examination was objected to, I did not press it in her present state, intending, however, to do so at a future time. To apply six leeches, and fomentation.

"June 1st.—Pain in iliac region removed. Apply six more leeches.

"6th.—At this time all the more urgent symptoms had disappeared; but the legs became enormously distended, and covered with one mass of petechiæ. The catamenia reappeared; excessive and pale. Discontinue the diuretic mixture. The legs to be bandaged. Ten minims of tincture of muriate of iron thrice a day.

"From this time the patient recovered most rapidly: the bloated cheeks, however, remained unchanged, showing that the cure was not yet complete. Ordered to bandage the face tightly with handkerchiefs, and to continue the iron. In a few days my patient had the satisfaction of seeing her face reduced to its normal proportions. The eczema entirely disappeared, and by the end of June she had not only regained her strength, but stated that she never felt better in her life. I now pressed for an examination of the swelling in the side, when she assured me that, after a minute examination, not a vestige remained.

"Here was a case of acute pulmonary œdema, supervening on chronic ascites and general anasarca, in a patient debilitated by long disease and inability to take substantial food. Her history was most unpromising, her brother having died of dropsy, her mother dropsical, and a sister, about whom I have since been consulted, in the same state. To a young practitioner like myself, it may be supposed that the case was one of no little anxiety; but still, after a most minute examination, being satisfied that no organic disease existed, and believing in the wonderful power of drugs when properly employed, I predicted a perfect recovery. But when the ascites had disappeared, and my attention was called to the tumour in the iliac region, my favourable prognosis was shaken. Had I continued the routine practice with diuretics, not only should I have failed in effecting a cure, but I anticipated a return of all the symptoms which had disappeared. What diuretics failed in, iron accomplished, and has, I believe, rendered permanent a cure which would otherwise have been of short duration. What would nature—what would the much-vaunted homœopathy have done in such a case? Allowed disease to have its sway, and hurry the poor patient with rapid and unerring strides to a premature and unnecessary death. Upon what pathological condition did the dropsical effusion in this case depend? Doubtless the more liquid portions of this greatly-impoverished blood found a ready exit through the walls of the capillaries, relaxed from want of their proper stimulus—a healthy blood. The action of the iron is then obvious.

"And now comes the most important question. What was the tumour in the iliac region? Could it be ovarian dropsy? Such was my diagnosis. But we are told that the contents of an ovarian cyst are never absorbed. The vaginal walls, however, may give way, and the contents be discharged by that channel. Was the supposed return, then, of the catamenia on the 6th of June such a discharge? I think it possible; but as a vaginal examination was not made, a doubt may exist whether the tumour was ovarian at all. Here is a tumour dating from a miscarriage ten years ago, gradually rising out of the pelvic cavity towards the abdomen, increasing as it proceeds; at times painful; movable; with defined outline and perceptible fluctuation. I ask, if not an ovarian tumour, what was it?

"The extracts I have made of this case seemed to me as few as were compatible with the right understanding of so important a subject."

Dr Harris, of the 15th Regiment of Bengal Infantry, reports a case of *Fissure of the Anus* which was cured by the knife in the usual way; and Dr Thorn, of the Harrow road, reports a case of the *Induction of Premature Labour*, slowly and successfully brought on by the agency of a drachm of the biborate of soda, three times a day, after the removal of the plug from the *os uteri.*

M. Claude Bernard's Lectures are continued in the 'Medical Times and Gazette.' Dr Goodfellow continues in the same journal his Lectures on *Bright's Disease.* We extract the following remarks on the *Proximate Cause of Anasarca:*

"*Proximate Cause of Anasarca.* — Various causes are in operation in the production of anasarca from kidney disease. That which is the result of the acute affections—when dropsy comes on rapidly in a few hours, and is almost the first indication of the disease—is not probably produced by the same causes as those which, singly or in combination, are so influential in the production of anasarca in the more chronic forms. The same may be said with regard to the nervous symptoms. There is no doubt that a cause suddenly coming into operation, before the system is in a manner prepared for it, may be productive of consequences which, if it came on, or acted, more slowly, so as to allow the system to accommodate itself to it—to acquire a tolerance for it—would not be of any serious nature. It may not be the same poisonous substance in the one case as in the other. Unfortunately we know nothing for certain with regard to whether urea, as urea, is a poison. Some allege that it is so, but only in considerable quantities; others affirm that it is only the salts into which it is prone to be converted. Some, again, assert that in the blood it always exists as urea, and becomes converted into different salts of ammonia by a ferment, when passing through mucous membranes, or shortly after it has passed through them. The experiments of Dr Hammond of Philadelphia, which were conducted with great care, conclusively prove that urea, when retained in the blood, either by disease or extirpation of the kidneys, is highly poisonous, and is sure, sooner or later, to kill; for however strongly the experiments of Bernard tend to show that after extirpation of the kidneys, the lives of the subjects of his experiments were preserved for some days by the elimination of the urea by the mucous membrane of the stomach and intestines, under the form of salts of ammonia, yet the animals invariably died as soon as the stomach became no longer capable of performing this vicarious office.

"Dr Hammond's experiments are of such great importance, and prove so conclusively the poisonous nature of urea, that I shall make no excuse for detaining you a few minutes in stating the results of them. I know you are aware (for I have always mentioned it in my systematic Lectures here) that Wœhler and Frerichs explained the uræmic intoxication by supposing that the urea is converted, through the agency of a ferment, into carbonate of ammonia in the blood. Dr Hammond was induced to perform his experiments for the purpose of deciding upon the correctness of this theory. The experiments upon which Frerichs founded his theory were these:—In the first series he injected a solution of the urea into the blood of animals whose kidneys had been previously removed. In from an hour and a quarter to eight hours they became restless and vomited. Ammonia was detected in the expired air, and, simultaneously, convulsions ensued. Death occurred in from two and a half to ten hours from the commencement of the experiments. Ammonia was found in the blood, the

contents of the stomach, and in the bile and other secretions. In the second series a solution of carbonate of ammonia (quantity not stated) was injected. Convulsions ensued almost immediately, and were quickly followed by stupor. The respiration was laboured, and the expired air was loaded with ammonia. The substance, however, gradually disappeared, and the animals recovered their senses.

"Now, with regard to the ammonia discovered in these cases, it must be mentioned that it has been found in the expired air of healthy individuals, and that, on the other hand, it frequently cannot be detected even in persons dying of Bright's Disease, when the urinary secretion has been in great part, if not quite suppressed. Some of you have seen the experiments tried in the wards, by means of a glass rod dipped in hydrochloric acid, without discovering a trace of ammonia. But this substance has also, like urea, been detected in the blood in health, and has often been met with as a constituent of the expired air of healthy persons.

"Dr Hammond's experiments also consisted of two series. In the first, the substances were injected into the blood of sound animals; in the second, the kidneys had been previously extirpated. The substances injected were urea, urea mixed with vesical mucus, carbonate of ammonia, nitrate of potash, and sulphate of soda. I shall only give you the results of those made with the three first. They were injected into the jugular vein in drachm doses, dissolved in four ounces of distilled water; and in the case of the second experiment, the urea was mixed with 115 grains of the mucus. All the animals exhibited some uneasiness soon after the injection, slight spasms of the limbs, followed by a disturbed sleep of two or three hours' duration; and on awaking out of it, they passed a large quantity of water, soon after which they were as well as ever. The carbonate of ammonia seemed to produce more immediate and violent symptoms, but yet the animal speedily recovered. In the two experiments with urea the dogs passed a much greater quantity of water after than before the injection, and also an increased quantity of urea, amounting to within about six grains of that which had been introduced into the blood. No ammonia could be detected in the expired air or in the water; while in the case of the injection of the carbonate of ammonia it was detected in both. In these experiments the urea produced some symptoms of poisoning, but, in consequence of its speedy elimination by the healthy kidney, they very quickly subsided, and the animals recovered. Much the same results have been observed with regard to other poisons; when, for example, arsenic, in no very large dose, has been taken into the stomach, and it has been speedily removed by vomiting. Symptoms of poisoning may have been present before the vomiting took place; but after the removal of the poison by vomiting they have gradually subsided. But let the poison remain, by the absence of vomiting in the one case, or the suppression of the excretion in the other case (with urea), and the symptoms will continue, and death more or less speedily supervene.

"In the second series, Dr Hammond, previous to the injection, extirpated the kidneys, and after the animals had completely recovered from the effects of the operation, and appeared lively, the same substances, in precisely the same quantities, were injected. In from forty-five minutes to an hour after the urea had been injected, the two dogs were seized with convulsions, which continued, with alternations of stupor, from six and a quarter to eight hours, when they died. There was no vomiting, no ammonia in the breath, nor any ammoniacal odour perceived in the examination of the bodies after death. Pretty nearly the same symptoms were observed after the injection of the carbonate of ammonia, and death occurred in about the same time. The symptoms came on somewhat earlier, and there was vomiting. Ammonia was detected in the vomiting matters, and in the breath.

"The condition of the system after extirpation of the kidneys is in many respects analogous to that present in Bright's Disease. In many cases, especially in the early stages of the acute forms, and in the later stages of the chronic forms, there is almost a suppression of the secretion. The statements of Dr Rees and others, that urea has been found (and these are very exceptional cases) in the blood in large quantities, when no very evident symptoms of uræmic poisoning have been observed, ought not to weigh against such evidence as this. In the case mentioned by Dr Rees, the kidney disease may have come on so slowly that the system may have had time to acquire a tolerance for the poison. There is no reason why a tolerance to some extent may not be slowly acquired for this, as we know it to be acquired for other undoubtedly poisonous substances. As I stated in my last lecture, urea is always present in healthy blood. It must of necessity be so. No physiologist, I believe, denies that the urea is merely separated from the blood. It is universally acknowledged now-a-days that the kidneys have no converting power. It cannot be supposed, therefore, that all the urea contained in the blood goes directly to the kidneys; and, therefore, it follows that only that quantity which passes through these organs is separated of this excrement at every successive revolution of the circulation.

"But not only has it been shown by experiments that urea is poisonous when introduced into the blood; M. Gallois has detected its poisonous properties when injected into the stomach. He injected urea (about five drachms) into the stomach of rabbits, and he found that it became absorbed, and passed through the circulation, and was excreted by the kidneys as urea, and that the animals died, all having exhibited the same symptoms. They were—acceleration of the respiration, weakness of the limbs, tremblings and startings of the muscles, general convulsions, tetanus, and death. Making allowance for the animals operated upon—rabbits—these symptoms resemble in many respects those which we observe in the human body in rapid poisoning by uræmia. But apart from the results obtained by chemists, vivisectors, and experimenters, the practical Physician has constantly irrefragable evidence, in cases of acute anasarca, of the undoubted poisonous influence of the urinous excrement when retained in the blood. No vivisector or experimental physiologist has either extirpated the kidneys, tied the renal arteries, destroyed the renal nerves, or in any other way arrested the renal functions without producing the symptoms of uræmic poisoning. But in all the cases of removal of the kidney the animal survived for several days, and the symptoms were not observed for a considerable time after the operation. In those, however, in which the urea had been introduced after extirpation, the symptoms invariably came on within the hour, and death occurred in from six to nine hours."

Having come to the conclusion that the urea itself is poisonous, or that the urea and extractives together are so, the Author proceeds to inquire how they act in the production of anasarca. He concludes that one way is by relaxing the walls of the capillaries, and converting them into inert tubes; and another way is by inducing the same effect upon the tubes, through an effect upon the nervous system, and also by impairing the chemical affinities, which exercise an important influence in carrying on the renal circulation. All these modes may assist, according to our Author, in inducing the result. He says:

"By one of these ways, perhaps by both combined, the transmission of the blood through the system is delayed—the red corpuscles accumulate, the vessels become distended, and their walls attenuated. During this condition the heart is acting tumultuously from the general inflammatory erethism present, and it is constantly propelling greater quantities of blood into the arterial system. You know the effect of all this. The blood in the arterial system is enclosed and pressed in canals, more or less elastic, more or less muscular; it cannot recede because of the valves of the heart, and it is only able to escape by traversing the narrow minute capillaries. Now, although the sum of these capillaries may be greater than that of the arteries with which they are continuous, yet anything which arrests or impedes the circulation through these capillaries, or the veins beyond, must augment the arterial tension—the arterial pressure. The force, then, with which the blood is pressed against the capillaries, distended, as I have shown them to be, by the action of the uræmic poison upon them—whether directly or indirectly, mediately or immediately—must inevitably lead to one of two things: either the escape of the serous part of the blood, or of that of the blood itself. If it be serum alone, there is anasarca; if blood, there is hæmorrhage."

Some interesting remarks follow on the causation of anarsaca in chronic cases.

Dr W. D. Moore contributes an analysis of a discussion that took place in the Swedish Society of Physicians, relative to the death-wound of King Charles the Twelfth. This paper is interesting in an historical point of view. It appears, upon a recent examination of the body, that the chivalrous king was not killed by an assassin, but by a missile shot by the enemy, and penetrating to the brain.

Dr Charles Taylor, of Liverpool, reports a case of *Saturnine Paralysis*. We extract it:

"W. H. G., male, aged forty-seven, married, a ship captain, came under my care on December 14, 1859,—a melancholy-looking, emaciated man, with cadaverous complexion and yellow conjunctivæ, vascular and respiratory organs normal, functions of abdominal viscera well performed; pulse 65; tongue moist, steadily protruded; no defect of articulation, skin clammy, senses and sensibility normal; gait steady. The breath has a peculiar fetor, and the gums are marked with a blue line at their junction with the teeth. Urine loaded with lithates, free from albumen, and yielding, on analysis, a trace of lead. States that he has had good health all his life, with the exception of an attack of fever, which occurred twenty years ago. It is upwards of a year and a half since he left the sea, and resided at Egremont, where his wife and himself habitually used rain-water that was stored in a leaden cistern. The effects of this water (which I found on examination to contain lead) were developed in both cases within seven months, when my patient began to feel ill, complaining of loss of appetite, dull gnawing pain in the epigastric region, succeeded by vomiting and obstinately-constipated bowels. Two or three Medical gentlemen were consulted; but not improving, he applied to the Northern Hospital, and on September 8, 1859, was admitted into the Royal Infirmary, where he remained upwards of two months. The principal symptoms were relieved by the treatment adopted, and he was discharged at the end of that time, suffering from complete wrist-drop of both hands.

"On desiring the patient to stretch out the superior extremities, the wrists fall in a straight line, and are neither adducted nor abducted (indicating equal paralysis of the extensor carpi ulnaris and extensor carpi radialis). In this position he finds it impossible to extend the fingers; but on supporting the first phalanges, the second and third are readily extended by the interossei and lumbricales muscles. The forearms generally are emaciated, and the thenar and hypothenar eminences are atrophied to a marked degree. He states that complete wrist-drop has existed for six months. On proceeding to ascertain the effect of the electric current on the paralysed muscles, I found the whole of the superficial layer of the posterior brachial region unaffected by the most powerful current, with the exception of the anconeus and supinator longus, in which the excitability was normal. Of the deep layer the supinator brevis was the only muscle on the right side that preserved its contractility; but on the left the extensor ossis metacarpi pollicis, extensor primi internodii, and extensor secundi internodii pollicis, in addition, acted readily. These and the supinators of both arms were also subject to the will. The muscles of the anterior brachial region acted well, as did, to a less degree, those of the thenar and hypothenar eminences; while in the palmar regions, the interossei and lumbricales preserved their electro-muscular contractility.

"I commenced the treatment on December 14, 1859, by passing a strong, rapidly-interrupted current, from primary and secondary wires, through each paralysed muscle in the posterior brachial region, for the space of two or three minutes; and this operation, with occasional omissions, which it is needless to detail, was repeated thrice weekly up to February 20, 1860,

when the natural tension and voluntary motion in these muscles was restored, although they still remained quite unaffected by the most powerful Faradic current. Those of the hand were not subjected to the electric stimulus, and remained in much the same condition, although slightly improved.

"This case appears to me to present some points of interest, to which I will briefly call attention :—

"1. The atrophy and paralysis of the muscles of the thenar eminences in both hands, as a result of the imbibition of lead, is worthy of note, as being opposed to a recent observation of Dr Duchenne of Boulogne, who attributes this atrophy, as formerly noticed by writers on saturnine disease, to the compression exercised by the handle of the paint-brush, in that class of workmen most frequently the subject of the affection. He says :—'Je viens de dire que les muscles de la main ne sont pas ordinairement atteints par le poison. Il est vrai que j'ai vu deux ou trois fois les muscles de l'éminence thénar considérablement atrophiés dn côté droit, chez des peintres atteints de paralysie saturnine; les muscles, quand ils ne sont pas entièrement transformés, conservent leur contractilité électrique. J'attribue cette atrophie à la compression exercée par le manche de la brosse, et non à l'influence toxique du plomb.'

"2. The exemption of the supinators, although receiving their nervous supply from the same source as the affected muscles, is almost constant in these cases, although I have seen the contrary stated ; but the fact that the three extensors of the thumb were paralysed only on one side is somewhat singular, and worthy of note.

"3. The subjection of muscles to the influence of the will by frequent applications of the electric current, although still rebellious to the most powerful shocks of that agent, is a singular fact that has been noticed by Duchenne and others, and might be a means of enabling us to diagnose pre-existing lead disease after recovery of the patient.

"4. The return of voluntary power in the wasted and completely paralysed muscles, by the treatment adopted, while those only partially affected, and not subjected to the electric stimnlns, remained *in statu quo*, is illustrative of the value of Faradism as a therapeutic agent in such cases.

"5. The ease with which the electric stimulus may be localised in deep-seated parts was well illustrated by this case, as I could readily pass a current through the superficial and deep layer of insensible extensors, causing violent contraction of the excitable flexors on the other side of the arm.

"6. I beg also to direct particular attention to the value of elastic straps in supporting the hand, in patients suffering from saturnine paralysis. The idea of employing these substitutes for splints was original, and I, at the time, believed it to be a novel contrivance. I learned, however, snbsequently, that Dr Iuman of this town had used an instrument precisely similar four years ago, which he described in the first volume of the 'Liverpool Medico-Chirurgical Transactions ;' nevertheless, although vastly superior to splints, it does not appear to be generally known. I may, therefore, mention that it consists simply of a piece of flat elastic, stiethed by one end to the back of an ordinary glove, the other being tied by tape above the elbow ; it costs a few pence only, and when applied, effectually supports the wrist, and permits the extensors to be exercised in proportion to their power ; it does not interfere with the aetion of the flexors, and by the support afforded to the first phalanges materially facilitates free play of the second and third. Its contractile nature also assists the patient in voluntary efforts to move the paralysed muscles, which *gymnastique nerveuse* to no slight degree aids in their restoration."

Another Specific Remedy for Cancer.—Three medical practitioners coming from the steppes of Kirghiz, a vast tract of land situated between the boundaries of China and Russia, have lately arrived in St Petersburg to offer a specific remedy for cancer. The Academy of Medicine of St Petersburg has refused permission to institute experiments in the hospitals to test the new remedy.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, June 26, 1860.

F. C. Skey, Esq., President, in the Chair.

A paper, by Dr Sydney Ringer, was read, on

THE RELATIVE AMOUNT OF SUGAR AND UREA IN THE URINE IN DIABETES MELLITUS.

Two cases, patients in University College Hospital, under the care of Dr Parkes, are given, in which the observations were made hourly over a considerable period, thus enabling the sugar and urea to be compared, under various circumstances, with greater accuracy. The following are the conclusions at which the Author has arrived :—1st. That after the influence of food on the urine has entirely disappeared, a constant ratio is maintained between the sugar and urea. 2nd. That after a purely non-amylaceous and non-saccharine meal, both the sugar and the urea are increased, but that during this increase the same ratio between them is observed. This ratio is 1 of urea to 2·2 of sugar. 3rd. That under both these circumstances the sugar could only be derived from the nitrogenous elements of the body, and, therefore, that some such a ratio might on *à priori* grounds have been expected. The Author next shows that after saccharine food has been taken, the sugar in the urine, as is well known, is increased, but that this increase of the sugar is accompanied by a decided increase in the amount of urea. Thus the sugar must cause a consumption of nitrogenous matter, probably resolving it into sugar and urea. Various kinds of sugar were given, each of which caused an increase in the amount of urea, though whether one kind more so than another is not shown. These facts are sufficient to explain the cause of the loss of flesh in diabetic patients. The Author next shows that the amount of urea excreted in proportion to the amount of sugar taken in as food varies in different patients, and in the same patients at different times ; and that the severity of the symptoms is in proportion to the amount of urea eliminated through the influence of the sugar, while no relation necessarily exists between the amount of sugar excreted and the severity of the symptoms ; indeed, as is well known, the quantity of sugar in the urine may greatly arise in amount with the improvement of the patient. The method of arriving at the influence of an ordinary mixed diet is to ascertain the ratio between the urinary sugar and the urea ; at least this method is sufficient in comparing various days together, provided the diet on these days be tolerably similar ; for, he states, it is possible to conceive that though the amount of amylaceous matter may cause a much smaller quantity of urea to be eliminated, yet by increasing the former in the meal, the latter may be maintained at the same amount, or even increased, but a more nitrogenous matter would have been taken in with the amylaceous ; the proportion of the former consumed would be much less, and consequently there would be more left to nourish the tissues. From this he thinks it is evident that the ratio must be obtained ; for as most, if not all, the sugar generally passes off, it can be taken as a fair guide to the extent of the meal. This will explain those cases in which the improvement of the patient is accompanied with a decided increase in the amount of urinary sugar. The Author shows, from the above cases, coupled with two others Dr Garrod allowed him to take, that a ratio of 1 to 4 of urea to sugar is rapidly fatal ; that life can be prolonged with a ratio of 1 to 8, while a somewhat rapid improvement is compatible with a ratio of 1 to 15. He next states that as the increase of the urea after a meal in health is probably due to the same cause as the increase under the same circumstances in diabetic patients, and as the sugar rises with it, maintaining the usual ratio (after a non-amylaceous meal), showing that they both come from the same source, if it can be further pointed out to what this increase in the sugar is due, it will explain the rise of the urea in health. After stating that it is possible that it may come from two sources, that it may be either due to some organ endowed with this function, which in diabetes is altered, or be the product of the retrograde metamorphosis of the tissue, he advances arguments to show that in these cases the sugar is due to the former, probably the liver. He thence concludes that the ordinary rise in the urea in health after a meal is due to that organ, which, in diabetes, produces a less highly elaborated sugar, the urea passing off unconsumed with the sugar. The Author concludes his paper with a few facts of lesser importance, showing that the sugar, after a mixed diet, reaches its maximum in the early stage of the disease, during the third or fourth hour ; while later, the maximum is not arrived at till the sixth hour. That after taking sugar in solution, the maximum is reached during the second hour. That the duration of the influence is longer later in the disease than at an earlier period : thus, at the commencement of the disease, the influence was lost in nine hours, while later in the disease it still continued after fifteen hours had elapsed. He also shows that the urea has a tendency to pass off earlier than the sugar, probably because it is more pernicious. Lastly, charts are given, showing the elevation of the temperature on several occasions after meals.

A paper, by Mr Hugh Croskery, was communicated by Dr A. W. Barclay, being

OBSERVATIONS ON THE INTERMITTENT FEVERS OF THE WEST INDIES, AND ON THE ACTION OF QUINIA AS A SPECIFIC IN THEIR TREATMENT.

The object of the Author in this communication was to point ont the necessity of a sedative treatment during the hot stage, and free purgation before the administration of the specific. The mixture he had found most beneficial was composed as follows :—Solution of acetate of ammonia, two ounces ; spirit of nitrous ether, and spirit of juniper, of each half-an-ounce ; potassio-tartrate of antimony, four grains ; tincture of hyoscyamus, two drachms ; tincture of opium, one drachm ; to twelve ounces of camphor mixture. Of this a tablespoonful is given to an adult every half-hour until diaphoresis comes on. The mixture may be either preceded or followed by ten grains of calomel, with a saline aperient a few hours later. He considered that the action of the mercurial purgative tended to assist the subsequent action of the quinia. He condemned the administration of quinine in large doses, and stated that he had obtained the most satisfactory results from its employment in small doses at repeated intervals. He believed that to administer it in any form during the paroxysm was injurious, and that the exhibition of large doses at this period of the disease was fraught with the greatest danger. The formula adopted by the Author for its administration is the following :—Disulphate of quinia, forty grains ; tincture of oranges, half an ounce ; dilute sulphuric acid, one drachm ; to ten ounces of water. Of this mixture he gives to an adult a tablespoonful every hour during the intermission, until singing in the ears, or the presence of headache, shows that the system is saturated by the remedy, when it is to be repeated at longer intervals, and even continued in small quantity for some days, so long as any unpleasant feelings are experienced at the time when the paroxysms ought to occur. He has found that in this manner from forty to sixty grains may be given before the recurrence of the attack, and that in the majority of instances the next paroxysm is either entirely prevented or is very much modified. One large dose of the salt very often produces disagreeable head symptoms, which prevent its repetition so as to get the system saturated with the remedy sufficiently early to obviate the return of the hot stage. In cases of severe quotidian he had occasionally given with benefit ten grains of quinine at once, along with the calomel ; this, however, he considered rather as the exception. The paper concluded with the narration of five cases illustrative of the Author's method of treatment. Of these cases four were adults, and a child nine years of age. In most of these the attack was quite recent, but in one case it had continued six weeks. The Author remarked that in such circumstances the prolonged use of quinine during convalescence was essential to ultimate recovery.

Mr T. Holmes, M.A., Cantab., laid before the Society an

ACCOUNT OF THE RE-DISSECTION OF A PREPARATION OF TUBAL GESTATION WHICH WAS PRESERVED AND DESCRIBED BY THE LATE DR JOHN CLARKE.

The paper describes a recent dissection made of a case of tubal gestation, which was described and figured by Dr John Clarke, in the 'Transactions of a Society for the Improvement of Medical and

Chirurgical Knowledge,' in the year 1793. Dr John Clarke's description pointed out only two membranes—the amnion and chorion—around the ovum in the tube. The principal object of this paper is to call attention to the existence of another membrane, external to the chorion, separable into two layers, and not forming part of the wall of the tube. The paper was accompanied by the original preparation, and a careful drawing of it in its present state.

THE DUBLIN COW-POCK INSTITUTION.

The following is the official answer to the statements that have been made respecting the management of this Institution :

Cow-pock Institution, Sackville street,
July, 1860.

Sir,—In reference to your communication, bearing date 14th July, 1860, requesting to be informed "on what grounds the Governors of the Cow-pock Institution make a charge for vaccine lymph, and whether they are prepared to reduce it," I am directed by the Governors of the Cow-pock Institution to inform you, for the information of his Excellency the Lord-Lieutenant, with respect to the first query, that the Cow-pock Institution, since its foundation in 1804, has been of necessity more or less a self-supporting one.

Government has from time to time, through the existing Lord-Lieutenants, accorded a grant to assist the Governors of the Cow-pock Institution in carrying out the intention thereof, viz., that of affording vaccination, *gratis*, to such of the inhabitants in and about Dublin as might please to avail themselves of it; and to be a source from which pure lymph, guaranteed as such by the Directors, might be obtained for public vaccinating institutions—for example, dispensaries, &c., and for private practitioners, for the vaccination of their patients. The sums that, from time to time, have been granted to the Cow-pock Institution by the Irish Executive never having, at any period of its existence, been sufficient to maintain it in proper working order without other resources, it was agreed that *poor-houses* and *dispensaries* should pay an annual subscription, in order that they should have an unlimited supply of fresh vaccine, whenever they required it; and as the Government grant was increased, this subscription was reduced to one-half, viz., *ten shillings and sixpence per annum*. Though these subscriptions added considerably to the income of the Institution, the demand upon it increased; its business augmented, and consequently its expenses. The Directors, therefore, did not deem it prudent, as yet, to do away with the subscription from private practitioners, of *ten shillings and sixpence per annum*, and the original charge of *half-a-crown for as much lymph as would keep up a source of supply, for dissemination amongst their patients*, to such practitioners as did not subscribe. These arrangements were sanctioned by the Executive.

The Directors request that it may be borne in mind, that this half-crown charge for lymph does not affect any but the richer classes of society, viz., those who have their private physician or surgeon to vaccinate them; that it in no way acts upon the vaccination of the people, directly or indirectly, and that the masses can avail themselves of free vaccination at any dispensary throughout the country, all of which have it in their power to call on the Cow-pock Institution for an unlimited supply of fresh lymph.

The Directors beg also to draw attention to the fact, that to those practitioners, and to such of the richer classes who may have failed in producing the characteristic vesicles, they invariably forward, on intimation of such failure, another supply free of expense. They continue to furnish it thus till the vaccination has been successful, from which, if care be taken, a continuous supply may be sustained.

With respect to the second question, "Whether the Directors are prepared to reduce the charge, viz., half-a-crown a packet for vaccine lymph?" I am directed to inform you, for his Excellency's information, that the Directors of the Cow-pock Institution have ever been anxious to be placed in such a position as to require no subscription whatever from workhouses, dispensaries, or private practitioners. In March, 1852, they addressed the Commissioners for the Relief of the Poor in Ireland, on the necessity of an uniform system of gratuitous supply to the workhouses and dispensaries under their control. And they requested to bring under the notice of the Poor-law Commissioners, and through them under that of the Executive in Ireland, a statement of the changes which would be required in their existing constitution, to enable the Directors to furnish all these bodies gratuitously. The document forwarded to the Poor-law Commissioners contained their reasons why the Directors of the Cow-pock Institution could not undertake such without further assistance from Government; and after a careful calculation, which was also forwarded, they came to the conclusion that a sum of 600*l.* in addition to their then grant (200*l.*)—which would be but 100*l.* per annum over its present average yearly income—would effectually carry out this arrangement. The Poor-law Commissioners forwarded the Directors' statement to the Chief Secretary for Ireland, who, by the direction of his then Excellency, transmitted it to the Lords Commissioners of her Majesty's Treasury, when the following reply to the Poor-law Commissioners was enclosed to the Directors :—

"Treasury chambers, Dec. 13, 1852.

"Sir,—The Lords Commissioners of her Majesty's Treasury having had under consideration your letter of the 25th ult., enclosing copy of an application made to the Poor-law Commissioners by the Directors of the Cow-pock Institution, Dublin, to be allowed to furnish a gratuitous supply of vaccine lymph to the workhouses and dispensaries throughout Ireland, I am directed to acquaint you, for the information of his Excellency the Lord Lieutenant of Ireland, that my Lords are not aware of any change of circumstances occasioned by the Medical Charities Act which should exempt the workhouses and dispensaries from payment for vaccine matter for their use, according to previous custom, in the same manner as they have paid and will continue to pay for all other medicines, means and appliances necessary for the discharge of their functions. Their Lordships therefore see no grounds for entertaining the application which has been made on behalf of the Cow-pock Institution.

"I am, &c. C. E. Trevelyan."

His Excellency the Lord Lieutenant will thus see that the Directors of the Cow-pock Institution were anxious to do away with all subscriptions from public institutions, and they are equally anxious not only to reduce the price of, but to remove the charge for, vaccine lymph, even to private practitioners, for the vaccination of those for whose vaccination they are either directly or indirectly paid. The Directors will be glad to be placed in such a position by Government as to give, gratuitously, guaranteed vaccine lymph to all who may require it. In conclusion, I am directed to inform you that the members of the army and navy, public schools, and county infirmaries, may obtain lymph free of subscription.

I have the honour to be, Sir,
Your obedient, humble servant,
H. L. Dwyer, M.D., Secretary.

To the Under-Secretary, Castle, Dublin.

DIRECTORS OF THE DUBLIN COW-POCK INSTITUTION.

Surgeons.—J. W. Cusack, Esq.; Robert Adams, Esq.; H. Irvine, Esq.

Physicians.—C. Johnson, M.D.; R. Collins, M.D.; Evory Kennedy, M.D.

Secretaries.—H. L. Dwyer, M.D., Secretary; E. B. Sinclair, M.D., and G. Montgomery, M.D., Assistant-Secretaries.

LEGAL INTELLIGENCE.

Charge of Manslaughter against a Druggist.—On Monday week an inquest was opened at the Grand Turk Tavern, Hockley hill, Birmingham, on the body of a married woman, named Sarah Sanders, before Dr Birt Davies and a respectable jury. Deceased, thirty-nine years of age, was the wife of a carpenter, living in Hockley hill, and the mother of three children, two of whom are living. On the previous Wednesday, deceased, who had been out in the town walking about during the afternoon, returned home, and, after partaking of a hearty supper, retired with her husband to bed soon after eleven o'clock. In about half an hour after she was seized with severe pain, which continued to come on at intervals for more than three hours. She was about five months advanced in pregnancy, and at her request her husband fetched Mr White, druggist, Handsworth, who had attended her in her last two confinements. A respectable married woman, Mrs Tocknell, was also called in by Sanders, and remained some time with deceased. Mr White came about a quarter-past four that morning, and stayed with deceased nearly three-quarters of an hour, administering medicines as the pains continued. He came again between eleven and twelve, but before his arrival Mrs Sanders had been delivered of a female child, Mrs Tocknell being present at the time. In this state of things Mr White, after giving the usual medicines (deceased being in a very weak state from hæmorrhage), advised that Dr Nelson should be called in. That gentleman came as soon as possible, and prescribed for the patient; but, before the medicines could be procured, Mrs Sanders died. It was also shown that, the "after-birth" adhering to the side, Mr White forcibly removed this with his hand. During the period referred to deceased had lost a great deal of blood.

Mr White was called, and, after receiving a caution from the Coroner that he was not bound to state anything which might criminate himself, gave the particulars just narrated, setting out very minutely the nature and quantities of the medicines he had administered to the deceased. The witness added that he had seen Mrs Sanders about six weeks previous to her death.

Dr Nelson stated that the immediate cause of the death of the deceased was hæmorrhage. He had formed an opinion as to the cause of such discharge, but declined to express it in the absence of a post-mortem examination of the body. In answer to questions from the jury, Dr Nelson, referring to the medicines administered to the deceased by Mr White, said that they were the proper and usual remedies applied in such cases.

At this stage of the inquiry Dr Davies intimated his opinion that it was indispensable a post-mortem examination should take place, and the jury, after a short conference, unanimously selected Mr Oliver Pemberton.

On the following night the inquiry was resumed by the examination of Mr Pemberton. He had made a careful and minute examination of the body of deceased, in company with Dr Nelson, who also again attended the inquiry. It has been already stated that Mr White, finding a portion of the placenta still remaining in the body, removed such portion with his hand. Mr Pemberton's examination of the organs of deceased showed that a laceration of a fearful character (six inches in length) had been caused, and the consequent shock to the system, and the ensuing hæmorrhage, ended in the death of Mrs Sanders. Mr Pemberton also said that, seeing the fœtus was only of between four and five months' formation, the removal of the placenta was quite uncalled for, unnecessary, and inexpedient. It was in the effecting of such removal by Mr White that the fatal injury just mentioned had ensued, as it was not possible for the passing of the fœtus to have caused such a disruption.

Dr Nelson confirmed the main features of Mr Pemberton's medical testimony, and evidence was called to show that no other person than White had in any way interfered with deceased.

Dr Davies, in summing up, said it was not for the jury to consider whether Mr White was qualified or unqualified medically; the question was, did he ignorantly or rashly act in the manner described. If the jury were of opinion that he thus acted, bearing in mind the medical testimony of Mr Pemberton, then they, in the proper discharge of their public duty, would find a verdict of manslaughter.

After some time spent in deliberation, the jury unanimously returned a verdict of "manslaughter" against Mr White.

Mr John Powell attended the inquiry at the second examination on behalf of the accused, who was not present.

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 15, 1860.

THE COLNEY HATCH LUNATIC ASYLUM.

Many of the philanthropic undertakings in which Englishmen engage are perverted from their beneficent purpose by an overweening passion for economy. We love to glorify our country as the home of Charity, and to gem our green vales with the turreted roofs of edifices dedicated to the alleviation of want and pain. We take a pleasure in carrying out any benevolent project; but, with a truly national reflectiveness, we sober our zeal with the pertinent question, "What will it cost?" We can never give the reins to a grand enthusiasm, and resolve to embody a principle in all its amplitude. We settle it by a unanimous resolution in full Committee assembled, that a good thing shall be done; and having chuckled at the success of this first step, we turn to the Estimates, and then the question arises, "How cheap!" If the aforesaid unanimous Committee do not divide and adjourn many times upon this perplexing consideration, they will scarcely deserve to occupy the responsible posts they are deputed to fill. It is possible that the benevolence of the design may be seriously perilled by the result of these discussions on the Estimates; still it behoves every honest and independent Committeeman to be on the watch against a job; and to effect a saving of 10,000*l.* is a triumph upon which an arithmetical philanthropist may glorify his name for the rest of his natural life.

It was a pious thought to take the poor lunatic from the hands of the parish overseer, who chained him in a filthy cell in the village workhouse, or locked him up in a cage that was planted in a shady part of the wild-wood away from the beaten paths of man, where his yells should ring unheard upon the passing gale, and his story become a legend of horror to stir the hearts of rustics by the winter fireside. It was a pious thought, too, to strike the manacles from his wrist and the hobbles from his feet; to learn to look upon him as the image of God broken—an object of compassion rather than of wrath, of sympathy rather than of punishment; to assuage the ebullitions of his distempered thoughts by a calm and tender sobriety of word and look, and to restore him to the liberty of a right mind by a perpetual forgetfulness of his transgression, and a vigilant searching out of all those vestiges of consciousness which might guide us by certain yet tedious steps to that dim retreat in the tangled maze of his intelligence where Reason still sat trembling upon her disputed throne. These were, indeed, divine aims; it is right now to ask, how have they been fulfilled?

The answer to this question is comprised in a report of an investigation, at Bow street, into the circumstances attending the death of an inmate of the Lunatic Asylum at Colney Hatch. It seems that the deceased had been liable to occasional fits of violence, and on one of these exacerbations was placed in the padded room, where he was subsequently found dead. After death, it was discovered that there was a large bruise on his abdomen, that his sternum was stove in, eleven of his ribs broken, and, on opening into the abdomen, that the liver had been ruptured, and that there was a large effusion of blood in the sac of the peritoneum. These are not the evidences of death from natural causes: when, therefore, the Commissioners of Lunacy became acquainted with the facts, they ordered the necessary legal steps to be taken to ascertain the perpetrators of the outrages that had so fatal a termination. Two of the attendants have been charged with having been guilty of acts of brutal violence towards the deceased, and have been committed for trial. We do not pretend to pronounce an opinion upon the culpability of the individuals so arraigned; there are, however, circumstances connected with the treatment of the insane, and with the establishment of Colney Hatch in particular, that deserve to be noticed.

The principle of the abolition of restraint in the treatment of lunacy as promulged by Gardiner Hill, and taught and practised by Conolly, is, in its entire and consistent development, one of the most praiseworthy and humane that have characterised the social progress of England during the present century. To carry out this principle, however, it is absolutely necessary that, besides a suitable construction of the hospital, there should be a sufficient number of attendants. It is an *expensive* system. Human forethought, watchfulness, and care must do the work of bolts and chains—than which they are, of course, somewhat dearer, though more efficient. When the non-restraint principle was originally introduced, this was the difficulty with which it had to contend. Dr Conolly encountered it at Hanwell; though, happily, being seconded by the energy and benevolence of Mr Sergeant Adams, he was enabled to overcome opposition.

This point gained, who shall keep the keepers?—who shall watch them, to see that they do not abuse the trust confided to them, and convert the hallowed principle of non-restraint into the most terrible and brutal tyranny which man can exercise over his fellow? It is obvious at once that this charge must devolve upon the Medical attendants; the only persons who, by knowledge, training, habits, character, and feeling, are competent for the task. But even they cannot do it unless they be sufficiently numerous to enable them to give a frequent personal superintendence to every case under their charge. In the present instance it is apparent that the Medical Officers did not or could bestow that personal care on the patient which his particular circumstances demanded. He had on more than one occasion been maltreated, even at length unto death; and yet the Medical Officers were utterly ignorant of his having been subjected to anything beyond the ordinary routine of the establishment. It does not appear that any record is kept of the daily state of the patients, or even of their exceptional fits of violence. How can Messrs Tyerman, Tucker, and Rose explain these circumstances?

Our view of the matter is this—that these gentlemen did their duty as well as they were able under the circumstances in which they were placed. The number of lunatics confined in the Colney Hatch Asylum is nearly two thousand; and the Medical Officers who are appointed to take charge of them are only two, exclusive of an Apothecary! How is it possible that these gentlemen can give that attention to the individual cases which humanity requires? We blame them not; the parties in fault are the County Justices, who have parsimoniously screwed down the establishment to this miserable standard of inefficiency. In place of two, there should be at least ten qualified men in charge of so gigantic an institution.

An unwise and unchristian economy is at the root of this abuse of philanthropy. In order to save an outlay of capital, a huge edifice is erected for the accommodation of ten times the number of lunatics that ought to be kept together under one roof; and, in pursuance of the same policy, not one-fifth the number of Medical Officers that would be sufficient to superintend such an establishment is allowed.

We believe this tendency to erect mammoth Asylums for the insane to be altogether wrong in principle and practice. It is unfavourable to the lunatic, whose well-being in a truly philanthropic system of treatment should be the first consideration; for it is absurd to suppose that a wretched creature who is surrounded by a little colony of persons as insane as himself can have a fair chance of improvement. It is unjust to the Medical Officers, who must be overwhelmed with anxiety if they endeavour conscientiously to discharge an impossible duty, or subside into

indifference under a sense of impracticability. Some time ago the Justices meditated the enlargement of this asylum; we earnestly hope that this intention will not be carried out, since it is obvious that the establishment is already much too vast and incommodious for efficient superintendence.

SUMMARY OF THE WEEK.

THE DUBLIN COW-POCK INSTITUTION.

We know that it is dangerous to cast a missile at a public institution—about as perilous indeed as to upset a hive of bees. A fortnight ago we called attention to the shortcomings of the Dublin Cow-pock Institution, having been moved thereto by the statements in a pamphlet published by Dr Long. Soon after, by the interposition of Mr Brady, M.P., the Government made inquiries into its government, and the result is a statement by the Directors, in which they endeavour to justify their proceedings. The Directors are very good men, and being so, we are only surprised that it should require so many of them to do the work of this Institution. There are three Physicians and three Surgeons, who are assisted by three Secretaries. No doubt these gentlemen are heavily taxed by their labours. They do not, however, rebut the accusation that Private Practitioners, who are non-subscribers, are charged two shillings and sixpence for two points of lymph; but they state that any Practitioner who subscribes ten shillings and sixpence a year may obtain a supply whensoever it may be required. They do not deny that Government grants the Institution 400*l.* per annum; but then there is a singular statement in the Report which puzzles our powers of comprehension. They say that in 1852 they were desirous of abolishing this charge of two shillings and sixpence a packet on Dispensaries, Workhouses, and Private Practitioners, and sent a document to the Poor-law Commissioners, showing that they were too poor to give the public the benefit of their generous intentions, but stating that "a sum of 600*l.* in addition to their *then* grant (200*l.*, which would be but 100*l.* per annum over its present average yearly income) would effectually carry out this arrangement." Now, after consulting all the Actuarial tables at hand, and knowing something, too, of the value of money, we cannot discover how an investment of 600*l.* can produce 100*l.* a year, or—or— but we really cannot understand the statement. What is their present income? Dr Long says that the Directors receive 400*l.* a year from Government, and the answer is furnished in this enigma. We hope that the Directors will oblige us by solving the riddle. Meanwhile we beg to reiterate that two shillings and sixpence is an exorbitant charge for two points of vaccine lymph; and when they assert that this charge "in no way acts upon the vaccination of the people directly or indirectly," we are sorry to say that we totally differ from them, and so does Dr Long. Such a charge, at any rate, in this Metropolis would not long be tolerated.

RESIGNATION OF SIR JAMES CLARK FROM THE MEDICAL COUNCIL.

We intimated some weeks ago that Sir James Clark intended to retire from the Medical Council—an intention that has at length been accomplished. The most important Members of the Council have now withdrawn from it, and it is deprived of the advantage of their experience, disinterestedness, and moderation. Those who have been left behind are, with scarcely an exception, there to combat for class and corporate privileges, without much regard for the interests of the Profession in their broad and general sense. Dr Baly has been appointed by Her Majesty to succeed Sir James Clark.

MEDICAL REFORM AND THE BRITISH MEDICAL ASSOCIATION.

The Medical Act, which the British Medical Association allowed to be mangled and emasculated, but which it did not originate, though its advocates are prone to assert that it did, has proved to be as distasteful to that body as to the rest of the Profession, if we may form a judgment as to its feelings from the proceedings at the recent meeting at Torquay. On the motion of Dr Richardson, a Committee was appointed to devise measures for the reform of the Medical Act, with especial reference to three points: viz., the deprivation of the power possessed by the Corporations of instituting special qualifications (the Dental qualification of the College of Surgeons, for example); the reconstitution of the Medical Council, so as to obtain a direct representation of the General Practitioners; and the introduction of some method of prosecuting persons illegally using any Medical title, so that the responsibility shall not devolve upon Private Practitioners. We congratulate Dr Richardson and the Association upon taking this step—albeit not altogether pleasing to Sir Charles Hastings—and we hope that it will not be long before they produce their Report. It is an attempt to repair the laches of which they were formerly guilty. The appointment of this Committee justifies every word that we have written in condemnation of this Act.

FRENCH SURGICAL PRACTICE.

There was a time when the fact of a young Surgeon having been a student for a session in Paris was a certificate of competency before which any advantages enjoyed in this Metropolis paled into insignificance. Parisian Surgery had the advantage of London ignorance; and as *omne ignotum* passes *pro magnifico*, it was estimated accordingly. Happily, however, the more liberal literary intercourse which has prevailed between the two countries during these few years past has furnished us with a better estimate of the relative scientific advance of the two Surgical Schools than we formerly possessed. Last week the 'Journal of Practical Medicine and Surgery' gravely reported a new method of treatment of ulcers and burns that had been adopted by M. Rossignol of Belgium, on the recommendation of M. Alex. Achard in the 'Journal de Bruxelles;' and this new method is described to consist "of a compress impregnated with cold water, protected by a water-proof texture, such as oil-silk or brown paper." Shade of Liston! Art is long; but it is longer still from London to Paris. Parisian practice would be improved, we think, by an occasional importation from the London Hospitals.

UNCERTIFICATED SURGERY.

The subjoined case is so astounding in all its details, that we can hardly find words to describe the gross ignorance of the man who had the presumption to undertake its maltreatment. It is equally astounding how the Jury could bring in a verdict of "Not Guilty."

"The deceased, Joseph Gregg, had been for some months afflicted with an aneurism of the aorta, or large artery adjoining the heart. The aneurismal sac had by pressure caused the absorption of a large portion of the sternum or breast-bone, and of the ends of the third, fourth, and fifth ribs; and having forced its way through, appeared like a large tumour or abscess, discoloured and whitish under the skin. The deceased had been to the Liverpool Infirmary, and had been attended by thirteen doctors, who told him they could not do anything to the tumour, and could do nothing for him. He was in intolerable pain, and sought out the prisoner, who told him he thought the abscess was not ripe, and he would see him in a week. The prisoner saw him, and the deceased begged of him to lance the tumour, as he could not bear the pain. The prisoner accordingly applied his lance to the surface of the tumour, and a quantity of yellow fibrine escaped, followed by clotted blood, and eventually by arterial blood. The prisoner tried to stanch the bleeding by sewing up the wound, and by applying flour and cobwebs to it. The deceased lingered from the 25th of February to the 3rd of March, when he died from exhaustion. On the part of the prosecution, it was contended that to lance an aneurism betrayed such a gross and culpable ignorance and rashness, that, the man having died in consequence, the prisoner was guilty of manslaughter.

"On the part of the prisoner, it was contended that he was a person not devoid of skill; that he had acted in good faith, and had exercised his best skill at the earnest request of the deceased; and that the fact of his not being a Medical Practitioner made no difference in point of law. It was elicited in the cross-examination of the Medical witnesses, that, except from the pulsation of such an aneurism, it would be very difficult to distinguish it from an abscess or a carbuncle, and that, covered as it was by fibrine and coagulated blood, the pulsation would be very weak; and on this evidence it was contended by the learned counsel for the defence that the prisoner, bringing fair skill and acting only at the urgent request of the deceased, was not guilty of either gross ignorance or culpable rashness, and, although he had made a mistake in the treatment of the deceased, acting to the best of his skill and ability, he was not on that account to be convicted of manslaughter.

"His Lordship, in summing up, referred to the dictum of Lord Ellenborough in Williamson's

case—'that to substantiate the charge of manslaughter the prisoner must have been guilty of criminal misconduct, arising either from the grossest ignorance or the most criminal inattention. One or the other of them was necessary to make him guilty of that criminal negligence and misconduct which are essential to make out a case of manslaughter.' His Lordship left it to the jury to say whether the evidence led them to either conclusion.

"The jury almost immediately found a verdict of 'Not Guilty.'"

REVIEWS.

On Asthma: its Pathology and Treatment. By Henry Hyde Salter, M.D.

A Treatise on Asthma is a novelty in our literature. For many years past, our observers and writers have ceased to regard Asthma in its concrete form, but, in pursuance of strict pathological theories, have referred its symptoms to special local lesions. Thus Asthma has been regarded as only a vulgar and old-fashioned term for heart-disease, emphysema, or chronic bronchitis. Indeed, Asthma is too vague a phrase to convey any satisfactory meaning, and even unlearned patients desire information more explicit than this term conveys. There is, however, a great convenience in practice in retaining terms which describe a synthesis of symptoms irrespective of the local alterations accompanying the disease, or the efficient causes that have produced it. Albuminuria is not a disease, but only the sign of one, or rather of many diseases; yet there is an advantage in retaining the term in our clinical nomenclature. The time has not yet come for a nosology based exclusively on the pathology of the solids; and it may be fairly questioned whether such a system would be much more accurate than one founded in the observation of symptoms, inasmuch as it would represent only certain effects of disease: in short, it would be a classified record of dead materials; whilst a nosology based on symptoms is, at any rate, a representation of actions in and states of the living body. The precise functional or molecular causes of disease may, for ages yet to come, elude our grasp; and, if known, would probably be too simple in their nature to afford anything more than the general rudimentary elements of certain groups of diseases, which would require more special classification to be brought within the sphere of science. We must be satisfied, therefore, at present, with the existing *rudis indigestaque moles* of medical nomenclature.

It is the misfortune of Dr Salter—though, with reference to the production of this treatise, not an equal misfortune of the Profession—that he is a sufferer from the horrors of asthma: hence his desire to record his experience of its phenomena, and to acquaint his professional brethren with the means which he has proved to be most efficacious in relieving the malady. Numerous articles from the Author's pen on this subject have already appeared in the Medical journals; so that our readers are in some measure prepared for a perusal of this book.

In the first chapter, the Author treats of the various theories that have been held respecting asthma. He objects to Laennec's division of asthma into two forms—one, "asthma with puerile respiration," the form called "nervous asthma" by Copland, and "hœmic asthma" by Walshe, though differently explained; that in which the "vital expansibility of the lungs is increased from a temporary augmentation of the respiratory necessities of the system,"—and the other, "spasmodic asthma," from a spasmodic contraction of the air-tubes. Dr Salter thinks that the first form is not asthma, any more than bronchitis is asthma. He says:

"There is an absence of the distress, of the characteristic wheeze, of the intolerance of the recumbent posture, of the evidence of deficient oxygenation, of the repetition of the attacks, of the periodicity, of the exciting causes—indeed, of every feature characteristic of asthma. It certainly is dyspnœa, and so is asthma, and that is just what they have in common, and nothing more; but to make that the warrant for calling them both asthma would be to call all forms of dyspnœa asthma—bronchitic, emphysematous, cardiac—indeed, it would be to make asthma and dyspnœa synonymous terms."

The Author agrees with Dr Walshe in considering that this dyspnœa most frequently consists in a diminished oxygenation of the blood. Dr Bree's theory, that the paroxysm of asthma is an attempt to get rid of peccant mucus; M. Beau's theory, which is very similar to it, and which regards asthma as a form of bronchitis; Dr Todd's theory, that it depends upon a poisoning, by a special *materies morbi*, of the nerves of respiration, or those portions of the nervous centres with which they are connected; Dr Budd's theory, that asthma is but the dyspnœa of emphysema, or heart-disease; Dr Walshe's, that it is in some instances caused by paralysis of the bronchial tubes—are all rejected. His own conclusions upon this point are thus stated:

"1. That asthma is essentially, and, with perhaps the exception of a single class of cases, exclusively, a nervous disease: that the nervous system is the seat of the essential pathological condition.

"2. That the phenomena of asthma—the distressing sensation and the demand for extraordinary respiratory efforts—immediately depend upon a spastic contraction of the fibre-cells of organic or unstriped muscle, which minute anatomy has demonstrated to exist in the bronchial tubes.

"3. That these phenomena are those of excito-motory or reflex action.

"4. That the extent to which the nervous system is involved differs very much in different cases, being in some cases restricted to the nervous system of the air-passages themselves.

"5. That in a large number of cases the pneumogastric nerve, both in its gastric and pulmonary portions, is the seat of the disease.

"6. That there is a large class of cases in which the nervous circuit between the source of irritation and the seat of the resulting muscular phenomena involves other portions of the nervous system besides the pneumogastric.

"7. That there are other cases in which the source of irritation, giving rise to the asthmatic paroxysm, appears to be central—in the brain; consequently, in which the action, though excito-motory, is not reflex.

"8. That there is yet a class of cases in which the exciting cause of the paroxysms appears to be essentially humoral."

The considerations that have chiefly influenced the Author in coming to these conclusions are—

"*a.* The *causes* of asthma; *b.* its *remedies*; *c.* its *associated and precursory symptoms*; *d.* its *periodicity*; *e.* the *absence of organic change*; *f.* the circumstance that the phenomena of the disease are *muscular*."

Among the *causes* of asthma, the Author enumerates fatigue, sudden fear, venereal or other excitement, and gastric irritation; among the *remedies*, "antispasmodics, sedatives, direct nervous depressants, &c.—tobacco, for example, stramonium, antimony, chloroform." With reference to chloroform, he remarks that a few whiffs will dispel the paroxysm, and—

"Remembering the action of the drug, that it is the nervous system to which it appeals, it is impossible to help seeing in this the most conclusive proof that the symptoms are due to a nervous cause."

This mode of argument is not convincing to us in proof of the exclusively nervous origin of asthma. The paroxysm is controlled by chloroform, it is true; so is the spasm in the convulsive diseases of children dependent upon disease of the brain, or upon dental or intestinal irritation. *Quoad* spasm, the chloroform acts beneficially; but is there nothing beyond the spasm which creates an extreme susceptibility of the nervous system? Again Dr Salter says:

"Nothing, indeed, in the whole range of pathological phenomena is to my mind more remarkable than the effect of emotion upon asthma. Dr Todd has told me that he has had patients come to him who have lost their asthma the moment they have entered his house; suddenly, and without any apparent cause, except the mental perturbation at being within the precincts of the physician, the difficulty of breathing has vanished. We see just the same thing in toothache—the sight of the dentist's house is enough to cure it."

Surely toothache is not "essentially nervous" in the sense that there is no positive pathological cause for it. We have known the pain arising from a carious tooth disappear in the manner stated; but there would have been no toothache had the tooth not been carious. So we say of cases of hysteria; there is always some abnormity in the system apart from the hysterical paroxysm. It does not answer the question, to reply that pain and spasm are essentially nervous. Pain and spasm are not essential properties of healthy nerve, but casual conditions of nerve in a morbid state, or under a morbid influence. What we want to know is, what are the causes that lead to these morbid sensations and actions of the nerves? We doubt, moreover, that in the case of toothache, or hysteria, or convulsive disorders generally, the cause is usually seated in the nerves themselves. Our belief is, that there are certain morbid states of the system that disturb the functional activity of the nerves, and thus produce the phenomena. We should like a little more explanation than we find upon the two propositions, "that the nervous system is the seat of the essential pathological condition," and that the "phenomena are those of excito-motory or reflex action." What is meant by the phrases "essentially nervous," and "essential pathological condition?"

Again the Author says that the *periodicity* of asthma implies its nervous character. Let Dr Salter explain himself:

"There are three kinds of periodicity in disease. One, in which it is produced by the periodical return of its cause, as in the recurrence of hay-fever every summer, the morning expectoration after a night's rest, indigestion every day at a certain time after dinner. Another, in which the periodicity seems to depend upon that ryhthmical impress which is stamped on the functions, that sort of diurnal oscillation in which the body is swung, by the constant recurrence, at one unvarying daily interval, of the habitual actions and passions of the body; I think that hectic and ague acquire their periodicity from this diurnal heat into which the body falls. But there are other diseases whose rhythmical recurrence cannot be explained on either of these suppositions, whose periodicity has no relation either to the diurnal interval or to the renewal of the cause, but which must be intrinsically periodic; such are epilepsy and asthma. In these the interval is long and of no certain standard—that is, though tolerably constant in the same individual, it differs very widely in different cases—the period is peculiar to each case, is an integral part of the pathological condition. This last kind of periodicity, and this alone, it is that points at all to the nervous nature of a disease."

Seeing, evidently, that the theory of periodicity would carry him too far, he assumes a periodicity which "has no relation either to the diurnal interval or to the renewal of the cause, but which must be intrinsically periodic,"—"in these the interval *is long and of no certain* standard,"—in short, a periodicity that is not periodic. We cannot say that, in the course of our observation of asthma, we have been able to trace any kind of *intrinsic periodicity which has no certain standard*; in fact, we cannot comprehend the phrase. We may observe upon this point, that periodicity is rather, to our minds, a law of organisation generally

than of a particular organ. The entire phenomena of life and motion prove this. Periodicity does not, then, necessarily imply the nervous character of a disease. What is ague? We go further: is even the existence of a nervous system necessary to periodicity? Vegetable life supplies the answer. The Author expresses himself in another part of his work more satisfactorily.

Another reason assigned for our Author's opinion is the possible "absence of appreciable organic change, as shown by *post-mortem* examination" when death has occurred from some other cause; and the last reason is "that the phenomena of the disease are muscular," thereby implying that the cause is nervous. We may have no difficulty in assenting to the proposition that the muscles are excited to action by the nerves, yet may not admit that the nerves would induce this action unless themselves disturbed by some organic change, or irritated by some remote disorder. The theory of the "*essentially nervous*" character of asthma does not convey a positive idea; it teaches nothing but a negation. Our observations apply to the insufficiency rather than to the positive incorrectness of the arguments put forth.

We have put our Author's views thus strongly, not from a captious feeling, but that his theory may be the better understood by the aid of his own explanation. He says:

"What, then, *is* the cause of the asthma in these cases? I do not see that we can say anything more definite than that it consists in the asthmatic tendency itself; in that special irritability of the pulmonary nervous system (as in the case of ipecacuan-asthma), or that general irritability of the whole nervous system (as in emotional asthma, &c.), which constitutes the asthmatic idiosyncrasy with which the individual was born.

"That in some cases a congenital asthmatic tendency does exist is strongly implied, I think we may say positively proved, by the undoubted hereditariness of the disease: in some families asthma is as much *the* disease as gout is in others. I have lately had under my care a gentleman whose father, paternal grandmother, and two paternal uncles, as well as himself, were asthmatic. Now, there is no doubt that what is inherited must be congenital—inborn.

"But, is any congenital peculiarity *necessary*? No; there appears to be no reason that a person may not *become* asthmatic; that the tendency to the disease may not be *acquired*—indeed, evidence as positive as can be imagined for believing that it may; that an asthmatic may at one time have differed in no respect from others, but that the tendency to his disease may have been engrafted on him by something that has happened to him. For example, the case of asthma as a sequela of measles, which I instanced just now. It is not conceivable that all the children whom this disease, or whooping-cough, leaves asthmatic, had any antecedent peculiarity. In no respect do they seem to differ from other cases, except that the disease from which the asthma dates has generally been of unusual severity.

"It would appear, then, that in respect to causation, all cases of asthma may be broadly divided into two groups:—

"1. Cases in which the essential cause of the disease—that which constitutes the individual an asthmatic—is some organic lesion, possibly not appreciable, either in the bronchial tubes, or in some part physiologically connected with the bronchial tubes.

"2. Cases in which any organic lesion is not only inappreciable, but non-existent; in which the tendency to asthma is due to something from within, not from without; in which the essential cause of the disease is a congenital, and possibly inherited, idiosyncrasy.

"I steer, therefore, a middle course between those who say that asthma always has at the root of it some organic disease within the chest, and those who deny that genuine spasmodic asthma ever depends on organic lung disease, and maintain that it is always a pure neurosis. I think I have shown, on the one hand, that there are numberless cases in which the supposition of any organic cause would be purely gratuitous, and in direct contravention of all clinical evidence and pathological reasoning; and, on the other, that we have every reason for believing that many cases, of the pure spasmodic variety, do really depend on some organic though inappreciable injury that previous disease has inflicted on the lungs."

So much, then, for the pathological cause of asthma. The following quotations give the Author's views of the proximate cause of the disease:

"But the dyspnœa of asthma tells a plainer tale than this; it tells us not only what it is not, but what it is. It gives the most positive evidence of narrowing of the air-passages. The asthmatic's breathing is what our forefathers called 'strait,' and what we call 'tight;' he feels as if a weight were on his sternum, as if his chest were compressed, as if a cord bound him, as if it would be the greatest relief to him if some one would cut his breast open and allow it to expand; he rushes to the window to get air, he cannot tolerate people or curtains about him, his clothes are loosened, and all the muscles of respiration tug and strain their utmost to fill his chest." . .

"In spite of the violent muscular effort there is hardly any respiratory movement; the parietes of the chest cannot follow the action of the muscles; on listening to the chest, the respiratory murmur is inaudible, even when not drowned by the wheezing; respiration is almost *nil*. Where, then, can this obstruction to the introduction and exit of air be? It must be in some part of the air-passages—the larynx, trachea, or bronchial tubes. In the larynx and trachea we know, from the symptoms, it is not. The fact of bronchial stricture, then, is certain."

This, then, is our Author's theory of the disease, and we cannot refuse his testimony, not only because he is a sufferer from the disorder, but because he has eliminated the question with extraordinary acuteness and intelligence.

We pass over the chapters relating to the clinical history of asthma, with the graphic descriptions of the paroxysms and the feelings and condition of the sufferer with which the book abounds, and come to that which relates especially to treatment. Dr Salter has great confidence in the influence of *depressants*—viz., ipecacuan, tartar-emetic, and tobacco; the latter being his favourite remedy. He says:

"As soon as their characteristic effect is established, the dyspnœa ceases—completely ceases from that moment; no matter how intense the spasm may have been, the moment the sensations characteristic of collapse are felt, it yields, the respiration is free, and the patient passes from agony to ease. It is one of the most striking things to witness, in the way of the effect of a remedy, that can be imagined."

More particularly he remarks:

"The effect of antimony nearly resembles that of tobacco, and it acts in the same way, but the nausea and collapse it produces are long and tedious.

"Of the three drugs, I should say ipecacuanha is the most manageable, and entails the least suffering; tobacco the most speedy and effectual.

"There are one or two practical points on which I would add a few words.

"Remedies of this kind, given with the view of cutting short the paroxysm, should be given as early as possible; and for two reasons. First, because it is much easier to break through the asthmatic condition when it is but just established; while the longer it is allowed to go on, the more inveterate and uncontrollable it becomes, and the more difficult it is to arrest it: indeed, its giving way at all may depend on the earliness with which the remedy is applied. I have known treatment powerless after the dyspnœa has continued for some hours, which never failed if administered as soon as it declared itself.

"Just at starting, in the earliest stages of the paroxysm, a very slight thing will determine its advance or retreat; and in proportion as it advances and deepens, in just such proportion do remedies become inoperative. The other reason is, that if the spasm *does* yield in spite of having been some time established, the recovery is not so complete as if the remedy had been applied immediately on its appearance. The longer the bronchial stricture lasts, the greater are the arrears of breathing and the resulting pulmonary congestion; and if this goes on unchecked and increasing for many hours, the disturbance of the vascular balance becomes so great, the capillaries of the lungs so loaded, that it is a long time, many hours, or perhaps even days, before that balance is restored, and the vessels recover their normal condition: and although the bronchial spasm may completely give way, there remains a certain amount of shortness of breath and an incapacity for exertion, and it is not until an abundant expectoration of mucus has taken place, by the pouring out of which the loaded vessels have relieved themselves, that the chest becomes clear and the breathing free. In asthma at once cut short there is no such accumulated congestion—no mucous exudation, and when the bronchial spasm ceases all dyspnœa vanishes. If on first awaking with the sensations of asthma the asthmatic nauseates himself with tobacco, or smokes his nitre-paper, or keeps himself in a standing posture, or in any other way cuts short the paroxysm, he will be throughout the succeeding day exactly the same, with the exception of the sleep he has lost, as if nothing had occurred; but if he suffers the fight between asthma and sleep to go on long, and then on the first remission of the dyspnœa lies back and goes to sleep, he will protract the asthmatic state, deepen the consequent pulmonary arrears, and not only postpone his recovery for many hours, but make it then slow and imperfect. I know an asthmatic who now never loses a day by his disease, in consequence of the promptitude with which he meets its first appearance in the early morning, but who formerly, from continuing to lie in bed and try to get sleep after the asthma had begun, protracted his sufferings through the day. He is attacked as often as ever, and at the same time—about three or four o'clock in the morning—but the moment he finds his asthma on him he takes measures to keep himself wide awake, stands leaning against a piece of furniture, and, if necessary, induces tobacco collapse, so that instead of a day's asthma he has half an hour's, and, as far as all the engagements of life go, has ceased to be an asthmatic."

Dr Salter objects to the use of opium, on the ground that sleep favours asthma by giving the ascendency to excito-motory action, and therefore would tend to increase rather than relieve the distress. He has also little faith in stramonium, it having, according to his experience, mitigated rather than cured the paroxysm. He is inclined to think, however, that the failure of the drug is in some degree owing to the mode in which it is prepared. Dr Salter has had but small experience of lobelia, and none of Indian hemp; his observations on these drugs have reference therefore to the testimony of others. Some excellent remarks conclude the volume, on the regiminal and dietetic treatment of the disease.

We cannot lay down this treatise without expressing our opinion that it is one of the ablest monographs that have appeared for many years. The subject is treated in a comprehensive and discriminating manner, with great power of analysis, in a style at once graphic, terse, and elegant. It will take its place in our library as *the* work on Asthma, and by the side of the best standard works on any subject.

Coal-Tar.—At a recent meeting of the French Academy of Sciences, a memoir by Dr Lemaire, on a new compound of coal-tar and its uses, was read. He says that coal-tar owes its properties to phenic acid, benzine, and naphthaline. Alcohol separates from coal-tar its active properties. When saponine, which dissolves fatty matters, is added, the result is a substance stated to be exceedingly valuable for its applications in hygiene, therapeutics, and natural history. The process is a discovery by M. Lebeuf, a chemist of Bayonne. Saponine is a peculiar principle extracted from saponaria officinalis, or soapwort.

The Library of the Royal Medical and Chirurgical Society will be closed from Monday, August 13, to Saturday, September 8, both days inclusive.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 98.)

It is surmised that John Hunter went into the army on account of painful disputes with his brother. It would appear that the envy and jealousy of William were not appeased or moderated by the unclouded success of his professional career, which at this time was unparalleled. That two such men should brood over passions which sullied and embittered their intercourse through life, is a painful phase of humanity, when a little concession on either side might have added much to the fame of both, and avoided criticism and censure. This unusual and extraordinary feud, commenced at an early period, and continued unabated to the end of their career, caused much scandal, and in John's case was attributed to defect of early education. The ties of blood, and similarity of pursuits, notwithstanding, held them together for twelve years. John Hunter took great delight in augmenting his brother's museum, and on his part the separation was regretted and long deplored. No doubt these circumstances, with the unsatisfactory state of his health produced by close confinement and application, decided his acceptance of the appointment on the staff of the army for foreign service. The break and change in his pursuits, a foreign climate and scenes, and active professional engagements of an army surgeon's occupation, were well suited to effect an improvement of his health.

This separation of the brothers had a good result in the temporary revival of William's latent affection for John, whom on his return he received most cordially. It is recorded by Dr Cogan, that in 1762-3 he would frequently speak, in his lectures, during his brother's absence, in the following terms: "In this I am only my brother's interpreter. I am simply the demonstrator of this discovery; it was my brother's." Dr Cogan adds, "The frequency of such expressions naturally inspired all his pupils with Mr Hunter's skill in anatomical researches, and of the Doctor's ingenuous conduct. (*a*) By thus keeping up the recollection, Dr Hunter established a high appreciation of the anatomical skill and research, as well as veneration and respect for John Hunter. He, moreover, promoted his interest by inserting three papers, prepared while his assistant, on anatomical subjects, which he also published in his absence, in a volume of the 'Medical Commentaries,' and thus kept his name alive amongst scientific inquirers. These papers related to the experiments on absorption, performed in the presence of a number of gentlemen who, as well as William, assisted and joined in the discussion on that occasion.

This campaign gave to John Hunter the *bonhomie* of a military man; he was extremely companionable, mixed freely in society, took his bottle, told his adventures, and enjoyed a laugh over a good story; and Mr Abernethy speaks of him as being, "moreover, a man of considerable humour." But his anatomical and surgical pursuits soon occupied all his time. It must, notwithstanding, be recorded that he was naturally playful. His slow method of speech, by affording him time to collect and condense his ideas, and point his humour, facilitated the display of that dry, droll repartee, — sometimes amusing, sometimes sarcastic, and never censorious, — which was so nearly allied to wit as to make him most agreeable society. His opportunities of studying varieties of character were numerous, to which his early training in country pastimes and manly pursuits gave a zest. They were not confined to scenes in his own station of life; he would pursue the instinct of contemplating the eccentricities of human character in various spheres, and under exceptionable yet grotesque conditions, as did Hogarth; and his professional engagements, no doubt, gave facilities to gratify this taste. He paid severely in his adventure to obtain the body of the Irish giant, O'Byrne. O'Byrne gave instructions in his last illness that his body should be taken out to sea and there deposited. For this object, he left a sum of money, took secret lodgings, and it was arranged that his body should be watched until that occurred. This came to the knowledge of Mr Hunter, who traced out where he died, the public-house where the watchers resorted when on relief from watching, and laid his plan to obtain the body by bribing them. He accordingly went to this place of resort, and personally undertook the negotiation by offering 100*l.* for the body, which was accepted. The watchers, finding they held a prize of no common value, and their customer very eager, threw out impediments, and demanded more and more money. At length John Hunter advanced the sum to 500*l.* on possession of the body. His real difficulty now commenced: possession of such a prize, under the circumstances, not only gave no security, but exposed him to serious implications, and compromised him for the moment both morally and legally. At a time when prejudice against dissection ran high, to be at the mercy of such people was a dangerous and imprudent position. On the removal of the body, he had his own carriage ready at hand, on the route, to carry it off to Brompton, where he had it immediately cut up, and the flesh boiled off the bones to avoid detection—which explains the dark hue of the skeleton, the bones not having been properly bleached during preparation; in other respects it is a beautiful skeleton, at present in the Hunterian Museum at the College of Surgeons. He now devoted himself assiduously to anatomy and the cultivation of natural history. To aid in the prosecution of labours which could not be conducted in the confinement of a densely-populous city, he purchased a piece of ground at Earl's Court, near Brompton, and built a house about two miles from town, where he could carry out his investigations and numerous experiments.

John Hunter's embarrassments were great—in consequence of which he taught practical anatomy and operative surgery for several winters, his half-pay and private practice not being sufficient to support him. Nevertheless, with very gloomy prospects, his industry prevailed, and the immediate difficulty of paying for the ground was liquidated, perhaps with some little help afforded by friends, from the arrears of pay remaining in the hands of the army agents, accumulated during active service. John Hunter took great delight in this suburban retreat, which he called his *Tusculanum*, where he spent in the summer all the after-part of the day, dined and slept, and found great relief from the fatigues of practice and lecturing. It was here that he projected all his schemes and experiments, and brought together that incongruous collection of beasts, birds, reptiles and insects, with fossils, shells, and numerous heterogeneous objects of natural history, including vegetables and plants, which formed the extraordinary family in possession of the house and grounds at Earl's Court. It is stated that in a paddock in the rear of the house, the most curious insects and reptiles would be seen crawling about, and associated together, described "as the strangest selection in nature." The front equally attracted notice: on each side of the parapet of the entrance portico was the figure, in stone or lead, of a lion *passant* painted red, and two more *couchant* on the ground on each side of the double flight of steps leading to the vestibule; and over the front door the mouth of a crocodile widely open, and a mound of shells piled up. This house soon became filled with his numerous collection of specimens and preparations; and upon marriage, great taste was displayed by Mrs Hunter, who possessed considerable skill as an artist, in the embellishment of a suite of rooms for occupation; inlaying the panels with her own drawings by an ingenious device, so that in the winter their removal to town could be easily effected. He was here enabled to make experiments to show the changes animal and vegetable substances undergo by the influence of gastric juice in the stomach; also by feeding animals with madder, which gives a red colour to the newly-deposited laminæ of bones, to show the process of their formation and growth. He at this time also discovered the process of exfoliation, by which dead is separated from living bone. To some of these experiments his brother William had alluded in the 'Medical Commentaries,' as named before. Inquiries and unceasing labours in comparative anatomy did not interfere with a series of numerous experiments John Hunter at the same time prosecuted upon living animals and vegetables, reared and collected at Earl's Court. In these favourite pursuits, no time or money was spared, and devotion to natural history and science found resources, notwithstanding the neglect and injustice which he considered had been hitherto bestowed by the world: he thus raised a lasting monument to his industry, perseverance, and enthusiasm." (*b*) It should have been named that in the year 1754-5 he discovered the structure of the placenta, and the communication between the mother and placenta. Dr Mackenzie, an assistant at that time to the celebrated Dr Smellie, and a friend of John Hunter's, showed him a specimen of a very curious and interesting kind; and John Hunter, in the presence of several others, succeeded in unravelling this structure, the anatomy of which had not been discovered. Upon reporting this to Dr Hunter, he at first treated it with good-humoured raillery, but accompanied John to Dr Mackenzie, and became satisfied of the importance of the demonstration. They afterwards took opportunities of making further and conclusive examinations to demonstrate the functions of the placenta. "Notwithstanding this, Dr Hunter in his lectures never took any notice of his brother's share in the investigation;" and in his splendid and elaborate work on the 'Gravid Uterus,' he accurately delineated and minutely described the anatomy and physiology of the parts, without once mentioning the author or the mode of the discovery." (*c*) "In May, 1754, Mr Hunter informs us that Dr McKenzie had been particularly successful in injecting the veins and arteries of a placenta: the appearance being new, he proceeded no further till he procured Mr Hunter's assistance in his examination. After having dissected, and made the whole into preparations," says Mr Hunter, "I returned home in the evening, and communicated what I had discovered to my brother, Dr Hunter, who at first treated it and me with good-humoured raillery, but on going with me to Dr McKenzie, was soon convinced of the fact." (*d*) It is related that Dr Smellie took so much offence at his pupil Mackenzie for thus supplying without his permission this specimen for John Hunter's demonstration, that they parted in consequence. The following is Mr Hunter's note appended to this article:—"Dr McKenzie being then an assistant of the late Dr Smellie, the procuring and dissecting this woman without Dr Smellie's knowledge was the cause of a separation between them, for the leading steps to such a discovery could not be kept a secret. The winter following, Dr McKenzie began to teach midwifery in the borough of Southwark."

GENERAL CORRESPONDENCE.

POOR-LAW MEDICAL REFORM ASSOCIATION.

To the Editor of the Medical Circular.

SIR,—In my last communication I laid before you a summary of the number of patients attended by each Poor-law Medical Officer. I now forward to you a list of thirty Unions, extracted from one out of the eleven divisions into which the Poor-law Board have divided England and Wales. In this list will be apparent the entire want of any plan in fixing the salaries of the Medical Officers, and the absolute necessity that exists for an Act of Parliament to determine the course to be pursued by the Poor-law Board and Boards of Guardians on the subject. At present the payments are capriciously made—the man with the least to do having, in many instances, the highest salary. This it is that prevents unanimity amongst us, and enables the Guardians to tyrannise over us, and the Poor-law Board to disregard our complaints. Within the last few days I have had remitted to me from ten officers of the Grantham, Auckland, and Narbeth Unions subscriptions to the amount of 4*l.* 5s. I have also received from

the students of the Manchester Royal School of Medicine 2*l.*, which assistance I value exceedingly, as it has been spontaneously afforded, and comes from gentlemen who are only indirectly interested in the success of our appeal for justice. I trust the Poor-law Medical Officers generally will see the necessity of supplying the Association with pecuniary assistance, as 200*l.* at least will be required to enable me to lay before the Members of the Legislature early next Session the calculations I have already made, and without which I fear the influence of the Guardians will have more weight than that of the Medical Officers.

I am, &c., RICHARD GRIFFIN.

12 Royal terrace, Weymouth,
August 6, 1860.

THE COMPOSITION OF CHLORODYNE.

To the Editor of the Medical Circular.

SIR,—In your number for this month you have inserted a formula for Chlorodyne, being, as you state, the result of my analysis. I beg to inform you that the formula is not correct, either as to its composition or mode of mixing, and shall feel obliged if you will publish in your next number the following formula, and mode of mixing the different articles, viz. :

℞ Chloroformyli, fl. ʒiv.
Sp. Ætheris Chlorici, fl. ʒij.
Morphiæ Hydrochlor., gr. viij.
Acidis Perchlorici, gtt. xx.
Olei Menthæ Piperitæ, gtt. ij.
Tr. Capsici, fl. ʒss.
— Cannabis Indicæ, fl. ʒj.
Acidi Hydrocyanici, gtt. xij. (Scheele's).
Theriacæ, ʒj. Misce.

The treacle is to be held over a spirit lamp until the fluids or watery part is evaporated, which is then to be rubbed up in a mortar with the chloric ether and tincture of capsicum until intimately mixed, when the other ingredients may be added and the whole shaken for some time in a phial.

Yours, &c., J. OGDEN, M.D.

Ardwick Villa, Manchester,
August, 8, 1860.

[We are glad to be able to give the foregoing authentic statement of the composition of Chlorodyne—a preparation which has hitherto been a mystery to the Profession.—ED. MED. CIRCULAR.]

THE NEW SYDENHAM SOCIETY.

ANNUAL MEETING.

The New Sydenham Society held its second annual meeting in the Club-room at Torquay, on Thursday, the 2nd inst. The Chair was taken by Sir Charles Hastings, one of the Vice-Presidents. The room was crowded.

The minutes of the former meeting having been read and confirmed, Mr Hutchinson, the Secretary, proceeded to read the annual report. Among the chief items of information conveyed in the report were the following :—1. That the Society now numbers 2850 members, and is still steadily increasing. 2. That the second edition of the first year's volumes had been almost exhausted, and that it had reimbursed the expenses attended the reprinting. 3. That the Council had finally decided on the issue of an Atlas of Illustrations of Skin Diseases, to be selected chiefly from those published by Hebra, of Vienna. 4. The issue of the first fasciculus of these Portraits will take place for the current year, and will probably be ready in December. 5. The Council hopes to be able to issue for each year's subscription the Annual Year-book and a fasciculus of the Portraits, and, in addition to these, two translated volumes. 6. Among the works at present in course of preparation are the second volume of 'Frerichs on Diseases of the Liver ;' 'Vogel and Neubauer's Handbook on the Examination, &c., of the Urine ;' Casper's 'Medical Jurisprudence,' and a reprint of 'Smellie's Midwifery,' with preface and annotations by Professor Simpson of Edinburgh.

In concluding the report, the Council urged upon the members generally the desirability of still further increasing the Society's numbers, in order to enable it to accomplish yet more for the promotion of Medical literature. It also desired to impress upon all that, in order to enable the executive to be prompt in carrying out the objects of the Society, it was absolutely essential that the subscriptions should be punctually prepaid.

In reply to a question, the Secretary stated that students, and all others connected with the Profession, were eligible as members, and that no form of proposal was needful, the payment of the year's subscription being all that was required in order to obtain the books.

The adoption of the report and balance-sheet having been moved by Mr Southam, of Manchester, and seconded by Mr Cartwright, of Oswestry, was carried unanimously.

The following gentlemen were declared duly elected as office-bearers for the ensuing year. Those to whose names the asterisk is affixed were not in office last year :—*President :*—C. J. B. Williams, M.D., F.R.S., &c. *Vice-Presidents :*—Sir Henry Holland, Bart., F.R.S. ; James W. Cusack, M.D., A.M., Dublin ; Robert Ferguson, M.D. ; H. W. Acland, M.D., F.R.S., D.C.L., Oxford ; John Macfarlane, M.D., Glasgow ; Thomas Mayo, M.D., F.R.S., President of the Royal College of Physicians ; J. Y. Simpson, M.D., Edinburgh ; *Thomas Turner, Esq., F.L.S., Manchester ; *Sir Henry Marsh, Bart., Dublin ; Thomas Watson, M.D., F.R.S. ; *George F. Evans, M.D., Birmingham ; William Fergusson, Esq., F.R.S. ; Sir Charles Hastings, Worcester ; James Paget, Esq., F.R.S. ; *Thomas B. Peacock, M.D. ; T. P. Teale, Esq., F.L.S., Leeds. *Council :*—*William Baly, M.D., F.R.S. ; Robert Barnes, M.D. ; John S. Bristowe, M.D. ; Robert Druitt, M.D. ; J. G. Fleming, M.D., Glasgow ; W. T. Gairdner, M.D., Edinburgh ; George Johnson, M.D. ; W. S. Kirkes, M.D. ; W. M'Ewen, M.D., Chester ; *M. Martin de Bartolomé, M.D., Sheffield ; J. Moore Neligan, M.D., Dublin ; John W. Ogle, M.D. ; *Edward L. Ormerod, M.D., Brighton ; Richard Quain, M.D. ; *George Rolleston, M.D., Oxford ; W. Sedgwick. Saunders, M.D. ; Robert W. Smith, M.D., Dublin ; William H. Stone, M.D. ; Thomas H. Tanner, M.D. ; *Hermann Weber, M.D. ; E. R. Bickersteth, Esq., Liverpool ; *William Bowman, Esq., F.R.S. ; Charles Brooke, Esq., F.R.S. ; *Henry Clark, Esq., Bristol ; *Edward Cock, Esq. ; *Prescott G. Hewitt, Esq. ; Peter Hood, Esq. ; George M. Humphry, M.D., F.R.S., Cambridge ; Jas. S. Millar, Esq., Edinburgh ; *Edward Ray, Esq., Dulwich ; *William S. Savory, Esq., F.R.S. ; Henry Thompson, Esq. —*Treasurer :*—G. Hilaro Barlow, M.D., 5 Union street, S.E.—*Secretary :*—Jonathan Hutchinson, Esq., 14 Finsbury circus, E.C.

The fact having been brought before the meeting, under the instructions of the Council, that the Council of the late Sydenham Society had unanimously voted its residue funds (about 300*l.*) to its successor, and that the same had been gladly accepted, it was moved by Mr Hadley, of Birmingham, seconded by Mr Soden, of Bath, and carried by acclamation—"That the special thanks of this meeting be conveyed to the Council of the former Society for its very liberal act in transferring its residuary funds to the New Sydenham Society."

As auditors of the Society's balance sheet for the current year, the following gentlemen were appointed :—Dr Stewart, Dr W. M. Cooke, and Mr Thomas Bryant.

It was moved by Dr Henry and seconded by Mr Southam, "That the warm thanks of the meeting should be given to the Hon. Local Secretaries of the Society, to whose exertions in so large a measure it owed its present very prosperous condition."

After votes of thanks to the retiring Council, to Mr Hutchinson, the General Secretary, and to Sir Charles Hastings for his kindness in presiding, the meeting adjourned.

OUR NOTE BOOK.

FATTY LIVER.—DEPOSIT OF THE FATTY MATTER IN THE CENTRE OF THE LOBULES.

By LIONEL S. BEALE, M.B., F.R.S.

In the specimens of fatty liver which I have hitherto examined, the fatty matter was deposited principally at the margin or *portal aspect* of the lobules. In the present instance, however, the cells near the postal surface of the lobules are comparatively free from fat, while this substance is present in large quantity near the intralobular or hepatic vein. The deposition of fat seems to have commenced in the centre, and to have spread from thence towards the circumference of the lobule. In the fatty liver of phthisis, and in other varieties of fatty liver, which have been described by authors, the oil globules are very numerous towards the circumference of the lobules, while often none can be detected in the centre. The accumulation of fatty matter at the outer part of the lobule is often so great as to map out the lobules most distinctly, the central part of each being surrounded by a broad belt of fatty matter which looks quite white by reflected light.

In the present instance the deposit of fatty matter took place differently, and must have been due to causes of a very different nature to those which determine this change in the liver generally.

The liver was obtained from a girl, aged 14, who was found in a field in a state of starvation. No history could be obtained, and her intellect was so much impaired that she was unable to give

any account of herself. She had probably endured cold and exposure, and had received but a very small allowance of food for a considerable period of time. She was admitted into the hospital in a state of extreme emaciation, and was placed under the care of Dr Todd. She lay in a dull, listless state, but never rallied, and died five or six weeks after her admission. No morbid condition of any organ could be discovered by the unaided eye. There was generally extreme emaciation, and an almost total absence of adipose tissue. The liver was the only organ I examined microscopically. It presented nothing remarkable on general inspection, and its size, colour, and consistence were normal. It contained little blood.

Now, in this case, it is clear that the presence of the fatty matter cannot be attributed to the existence of a large quantity of fat in the portal blood. It can therefore hardly be referred to increased nutrition of the cells. It is very improbable that in such a case the cells should have possessed an increased power of attracting fatty matter from the blood. It would seem as if the nutritive processes were almost entirely suspended, and although life was prolonged for a considerable period, the waste seems to have continued in spite of every attempt to introduce a sufficient quantity of nutrient materials into the organism. Why did not the cells at the circumference of the lobules, which are the oldest, undergo a morbid change before those in the centre? The most important changes occurring in the healthy organ undoubtedly takes place in these cells. The portal blood, rich in fatty matters and other constituents recently absorbed from the intestine, reaches these cells first, and before it arrives at the centre of the lobule, certain substances entering into the formation of bile are doubtless almost entirely removed. Here the circulation is slowest, and in this part of the lobule the most active secretion of bile undoubtedly occurs. It is in this situation that the changes in fatty liver and those in cirrhosis of the liver undoubtedly commence. It must be borne in mind that the cells grow from the centre towards the circumference of the lobule, the youngest cells being always found in the former, the oldest in the latter situation. The *development* and multiplication of the cells then appear to take place near the hepatic vein, where the circulation is most rapid; their *growth*, as they pass towards the circumference of the lobule where the blood is distributed over a great extent of surface, and the circulation comparatively slow.

The accumulation of fatty matter in the present case would seem to be due to changes affecting the development and early growth, rather than upon those connected with the secreting action of the cells. It is difficult to explain the manner in which the fatty matter is produced, but it is not unreasonable to suppose that the material so closely resembling oily matter in its microscopical characters, which seems so intimately connected with the formation of nuclei, should accumulate to an unusual extent in a case where the conditions necessary to the complete development of the nucleus, and the material which surrounds it, are not present. There would seem to be a greatly-increased proportion of fatty matter in this part of the lobule without any absolute increase, and possibly even with a diminution in the total amount of hepatic tissue entering into the formation of the lobule. Probably some constituents present in a normal state are entirely absent in this instance. The force to which their separation from the blood and their conversion into the materials of the normal cell is due is wanting, and substances which ought to have been converted into the material of which the cells are composed, and from which the bile is formed, remain in a crude state and assume the form of fat globules, as has been described. At the same time, it must be admitted that this explanation is not very complete or satisfactory, and it is offered only in the hope that more light may be thrown upon the subject in future investigation.

In Fig. 1, Plate II, the general appearance of a thin section of the liver in which the portal vein had been injected is shown — a portion of a lobule more highly magnified in which the branches of the hepatic were injected is figured immediately below this (Fig. 3). The large oil globules in the centre of the lobule are well shown, and their gradual diminution towards the circumference, where the tubes appear to be filled with brown granular matter, is represented. Below this figure some of the collections of oil globules are seen. In Fig. 7, the branching of the duct and its connection with the tubular network is very distinct.

In these drawings there is little indication of the existence of true cells; indeed, it is very difficult in many diseased specimens to detect anything like a liver cell as it is usually described. The free portions observed are certainly not enclosed in a cell membrane, but appear to be fragments irregularly broken off from the mass which occupies the tubular network. Many portions were observed closely resembling those figured in which there was not the least cellular appearance. I have already alluded to this subject in the 'Anatomy of the Liver,' page 47, and I propose to discuss this important question in its numerous bearings in a future communication.

The conclusions derived from an examination of this liver may be summed up as follows:

1. The fatty matter exists in the central part of the lobules, and diminishes in quantity towards the circumference.

2. The changes probably are connected with the development and early growth of the cells, not with their secreting action.

3. The nuclei of the cells are destroyed and degenerate, or are not formed at all in that part of the lobule where their multiplication takes place in health, and oily materials which would have been altered during the development and multiplication of nuclei remain in a crude and unaltered state.—'Archives of Medicine.'

CAUTERISATION.—A CURE FOR FISSURE OF SOFT PALATE.

Professor J. Cloquet communicated to the Academy of Sciences a highly interesting surgical case, forwarded through him to the Academy by M. Benoît, Professor of the Faculty of Medicine of Montpellier. It was an instance of congenital fissure of the soft palate, cured by reiterated cauterisation.

The deformity, which interested the soft palate only, was attended with all the symptoms it is capable of producing. Merely a few words could be pronounced, and so disfigured that even the child's parents were unable to understand them; deglutition was impeded, solid and more especially liquid substances returning through the nose; expuition was utterly impossible, the saliva or mucous secretions involuntarily dropping from the mouth, or being expelled by automatic movements of the tongue. The poor child had attained his eleventh year, and time had in nowise ameliorated his condition, when M. Benoît undertook the case.

The treatment was begun on the 8th of May, 1857, and was twice interrupted, once by a journey, and on another occasion by the measles; the time thus lost being deducted, the cure occupied nineteen months.

The soft palate has now entirely united, the uvula only remaining bifurcated. The symptoms have all disappeared; the articulation of words is easy, but the tone of the voice still somewhat impaired; the patient speaks a little through his nose, a circumstance referred by M. Benoît more to habit than to the insignificant fissure which remains. The Author supports this assertion by adducing the case, still under his observation, of a man bearing a congenital division of the uvula, nearly similar to that which persists in the patient whose history has been related above, and in whom the articulation of words is perfectly natural. M. Cloquet has had occasion to make the same remark in one of the cases he has published.

In M. Benoît's patient the favourable result was effected by thirty-three cauterisations, fourteen of which were performed with the proto-nitrate of mercury, and nineteen with the lunar caustic, applied, in accordance with M. Cloquet's precept, at the angle and edges of the fissure in an extent of one or two lines only. The child, who at first dreaded the operation, has become so indifferent to it that he now spontaneously requests to have it performed: M. Benoît therefore intends to attempt the union of the bifid uvula, and entertains no doubt of ultimate success.

This is, therefore, a fresh instance of union of cleft-palate by reiterated cauterisation, in a young and timid child, for whom staphyloraphy could not for several years have been thought of. The treatment was so free from pain, and interfered so little with the boy's occupations, that his education, hitherto entirely neglected in consequence of the deformity, was entered upon during the progress of the treatment, and has been prosecuted with such success, that in October 1858 he was admitted into the Montpellier College, where he gradually rose to the first places in competition with his school-fellows, and obtained at the close of the year six nominations and one prize for *recitation*. "The latter premium," justly observes M. Benoît, "is a superabundant proof of the satisfactory pronunciation of this child, who, previously to the treatment, spoke unintelligibly even for his parents."

"There are cases, however," said M. Cloquet, "in which cauterisation is insufficient to cure split-palate; I refer to those in which the palatine bones are divided; here autoplasty becomes necessary; but, as M. Hippolyte Larrey has remarked in a recent publication, cauterisation may be of much assistance in promoting the cure. It would be possible," says this eminent surgeon, "to turn this procedure to profitable account, even in those cases in which otherwise it might be unavailing, when, for instance, autoplasty has achieved but incomplete results and a small aperture remains."

The method of cauterisation seems to have become more general, and M. Cloquet mentioned an admirable result obtained by M. Gaillard, surgeon of the Hôtel-Dieu of Poitiers, not, it is true, on the velum, but on far more complex organs, in the case of a little child who was born with deformed hands and feet. Both feet were bifid in almost the whole of the anterior half, and resembled the claw of a lobster. It would have been difficult for the infant even to walk, and the use of common shoes would have been utterly impossible. M. Gaillard rendered the edges of the fissures regular, and, by successive cauterisations of the angle of the division, effected sufficient union of the disunited halves of each foot to allow of the child, who is now four and a half years of age, wearing tight shoes and walking with perfect ease.

Upwards of thirty years since, by the same procedure, M. Cloquet succeeded in effecting the union, in the case of a young man, of the two halves of a congenital bifid thumb (two small phalanges existed, each provided with a narrow but distinct nail). A deep longitudinal furrow persisted at the junction of the two nails, which, instead of being divergent, became parallel to each other, and the thumb, thus nearly restored to its natural shape, recovered the regularity of its functions.—'Journal of Practical Medicine and Surgery.'

ON THE TREATMENT OF PRURIGO.

The Author (Dr von Bärensprung) warns his readers against the employment of stimulating agents. Local anæsthetics, as, for example, chloroform, are also useless. On the contrary, cold baths, cold ablutions, and applications to the skin, procure relief and quiet; tepid baths, bran baths, and vapour baths, allay the increased excitement. Anointing the skin with mild fatty matters, and inunctions with lard, are also suitable means of procuring alleviation of the patient's sufferings. The Author enumerates the preparations of sulphur, tar, and sublimate, as specific remedies. Slight cases of prurigo are undoubtedly often cured by sulphur baths and sulphur ointments. In obstinate cases the Author obtained remarkable effects from baths of sublimate. The patient takes every second day, or at longer intervals, a bath at 95° Fahrenheit, in which two drachms of sublimate are dissolved; in general six such baths are sufficient to effect a perfect cure. The absorption of the sublimate is in this case very trifling, and its action is mainly local. It is necessary to remark that the bathing-vessel should be constructed of wood, and not of zinc or copper, as, if these metals be employed, not only is the vessel itself destroyed by the decomposition, but the bath is rendered inefficacious.—'Vierteljahrschrift für die Praktische Heilkunde,' 1860. Band lxv., 'Analekten,' p. 65.

ON A NEW FORM OF CHLORIDE OF SODIUM.

By M. Tuson.

Lately, on opening a tightly-fitting tin box, in which a quantity of salmon-roe paste had been allowed to remain for nearly three years, it was found that the organic matter was covered by an efflorescence of acicular crystals. One of my pupils collected some of these crystals, analysed

them, and pronounced them to consist entirely of chloride of sodium. As I had never heard of chloride of sodium crystallising in needles, their examination was repeated, but still the same results were obtained. Some of the crystals were next dissolved in water, and the solution produced submitted to spontaneous evaporation, when the whole of the salt deposited in the ordinary or cubical form. This result, therefore, fully confirms the conclusions dedneed from analysis.

The crystals, some of which are nearly half an inch long, appear to be rectangular prisms terminated by four-sided pyramids. They are beautifully clear, colourless, transparent, elastic, longitudinally and transversely striated, and many are bent or contorted in a manner similar to the native hydrated sulphate of lime called selenite by mineralogists. The acicular crystals are anhydrous, and undergo no change in form or diminution in transparency when exposed to air at ordinary temperatures, or even at a low red heat. The needles of chloride of sodium possess one property which is a very familiar characteristic of the cubical salt—namely, that when heated they decrepitate. It is singular to remark that, at all events as far as we know at present, the acicular varieties of the chlorides of potassium and of sodium are only developed in the presence of organic matter, just as the production of octahedral chloride of sodium appears to be due to the solution from which it crystallises containing urea. Since writing the foregoing, I have observed an efflorescence of acicular chloride of sodium on an animal deposit which was sent me for analysis, and which had been originally mixed with a solution of common salt to prevent it undergoing putrefaction.

ON RETENTION OF URINE IN FŒTAL LIFE.

M. Depaul, the eminent Paris obstetrician, has just concluded, in the 'Gazette Hebdomadaire' of the 8th instant, an important paper on the above subject. The research, lucidity, and practical value of the essay are very great; and we are sure that it will be read with benefit by all who are interested in obstetric practice. Amongst the concluding propositions, we remark the following:—"The difficulties which may arise from the distension of the fœtal bladder are such that, in several cases, the head and limbs were torn off without surmounting the obstacle. This distension cannot be detected before parturition, but may be suspected during labour. It can be made out clearly only by the hand introduced into the uterus. When tractions are useless, we should think of puncturing the bladder; and this should be done with the utmost nicety, as the distension of the urinary receptacle does not lessen the viability of the child. After birth, it may become practicable to perform a second operation, by which the obstacle to the escape of the urine may be removed and the child eventually be saved."—'Lancet.'

COLOURATION OF THE BONES OF THE FŒTUS BY MADDER GIVEN TO THE MOTHER.

M. Flourens says: "It is near twenty years since I presented to the Academy (3rd Feb., 1840) two or three skeletons of pigeons, reddened by the action of madder, which had been mixed for a certain time with the food of those animals. The last experiments of this kind, made in France, were by Duhamel in 1739, just a century before mine. The experiments of Duhamel were almost forgotten, mine were received with curiosity by physiologists. At the meeting of the Academy on Feb. 24, 1840, passing from my observations on birds to those of mammals, I presented to the Academy the skeletons of two or three puny pigs whose bones and teeth were completely reddened by the action of madder mixed with the food. To-day I present to the Academy a fact much more curious, and, as I believe, quite new. Not merely are the bones of the animal itself nourished with madder, but those of the fœtus also are reddened, and of much deeper colour, by the single circumstance that the mother has been submitted to a diet mixed with madder during the last forty-five days of gestation. Not only have all the bones become red, but the teeth also, and what is remarkable, in a manner much more complete and uniform than when the fœtus being born, is itself submitted, so soon as it can eat, to the madder régime. So much greater permeability does the tissue of the embryo afford to the circulation of the blood of the mother. But it is only the bones and the teeth which become thus affected. Neither the periosteum, nor the cartilages, nor the tendons, nor the muscles, nor the stomach, nor the intestines—nothing, in a word, which is not bone, is thus coloured. I can show to the Academy three pieces which are three parts of the same skeleton. The first is the right tibia. All the bone is red, but neither the periosteum nor the cartilage is at all so. The second piece is the left tibia; a shred of periosteum has been detached at one point, and it is seen to preserve its ordinary white colour. The third piece is the rest of the skeleton. One may remark above all the teeth which are perfectly coloured. The sow which gave me this fœtus produced five at the birth. Two were dead, and both were found equally coloured. Three others live, and we may judge by the colour of the teeth that of the rest of the skeleton. The mother does not communicate directly or immediately with the interior of the fœtus except through the blood. Now, the connection of the blood of the mother with that of the fœtus, in whatever mode that may be, which I shall examine in another note, is a fact full of consequences. How does the fœtus respire? How is it nourished? Evidently through the blood of the mother. All physiologists have also thought and said so. But does the blood of the mother communicate with that of the fœtus? Here is the whole question, and by the specimens which I bring before the Academy one may see that it is resolved. The blood of the mother communicates so fully with that of the fœtus, that the colouring principle of madder, the same principle which colours the bones of the mother, colours also the bones of the fœtus."—'Comptes Rendus' and 'London Medical Review.'

APPLICATIONS OF IODINE TO THE CERVIX UTERI IN THE VOMITING OF PREGNANCY.

Dr Miller relates some cases in proof of the frequency with which the vomiting of pregnancy is dependent upon an inflamed state of the cervix uteri, and of the efficacy of the practice which consists in painting it freely with an ethereal tincture of iodine, composed of half a drachm to one drachm of the iodine to one ounce of sulphuric ether. Dr Miller adds that he and his Medical friends have during the last ten years employed this formula as far preferable in inflammatory affections, especially erysipelas, to tincture of iodine.—'Boston Medical Journal,' vol. lxi., p. 70, and 'Medical Times.'

DEATHS.

CAMPBELL.—July 20, at 221 Gallowgate street, Glasgow, suddenly, from the bursting of a blood-vessel in the head, James Campbell, L.F.P.S. Glasg., aged 50.

HENRY.—June 27, at his residence, Belleville, Canada West, Walter Henry, M.D., late Inspector-General of Hospitals, aged 69.

KNIGHT.—June 14, at Bijnore, East Indies, Dr R. C. Knight.

LAMB.—June 21, at Mussoorie, East Indies, Dr M. B. Lamb.

MACKESEY.—June 21, *en route* for Calcutta, Dr William Mackesey, aged 32.

RENDELL.—July 30, at 111 Euston road, William Rendell. He was Surgeon in the army in the Peninsula under the late Duke of Wellington. He also served in the Walcheren Expedition and in Canada.

ROBERTS.—May 14, suddenly, at Butcher's Island, Bombay, William O. Roberts, Assistant-Surgeon to H.M.S. 'Retribution,' aged 26.

ROBIQUET.—Edmond Robiquet, Professor at the Paris School of Pharmacy, and one of the most distinguished Pharmaceutical Chemists, has just died, in the 38th year of his age.

SCHLOSSBERGER.—July 9, at Stuttgart, Dr Julius Schlossberger, Professor of Chemistry at the University of Tübingen, formerly Assistant to the late Professor Gregory, Edinburgh.

TURNER.—August 4, at Bexley Heath, Kent, John Cusson Turner, formerly of Brighton, M.D., &c., aged 47.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College, at a meeting of the Court of Examiners, on the 2nd inst.:—James Jackson Adair, Douglas, Isle of Man; Ponsonby Kelly Adair, Lincoln's-inn Dispensary; William Shepheard Bennett, Plymouth; George Colby, New Malton, Yorkshire; William Henry France, Sheffield; Goorequer Griffith, Dublin; Robert Iliffe, Coventry; Thomas Auchmuty Keating, Springfield, Guelph, Canada; John Henry Charles Erridge King, Portsmouth; Alexander Neil, India; Arthur Henry Nowell, Richmond; Cornthwaite Hector Rason, Eastbourne; William Arthur Rush, Southminster, Essex; Samuel Coseley Smith, Staffordshire; Charles Gordon Sprague, Kimbolton; Charles Henry Hilton Stone, Manchester; William Thomas Winter, Cotham, Bristol.—The following gentlemen have lately passed the Anatomical and Physiological Examination:—Messrs Wm. Michael Whitmarsh, Philip B. Henry Ayres, Thos. P. Wright, Haslar. Harris, John Thomas Henry West, Douglas John Dutton, John Nash Smart, Ponsonby Kelly Adair, Heber Dowling Ellis, Louis Ernest Dnmaine, Henry Edward Jessop, Henry Geo. Williamson, Chas. Maslew Deane, Thos. Heath Curtis, Henry Chas. Woods, John Fleming, Michael Benny, Lynch Thomas, Henry Howell Parry, Philip Rich. Tomlinson, Christopher M. Davidson, Warner Atkinson, Wilmot Horton Trevor Power, Joseph Silverthorne Belcher, John Dunstan, Wm. Henry Dixon, John Oliphant, Theophilus Geo. Husband Nicholson, Henry Edward Langford, Wm. Spalding, Anthony Robinson Oliver, Edmund Willett, Samuel Henry Ramsbotham, Francis Griffiths, Edw. Clapham, Edward Dodd, Fred. Steel, Thos. Simpson, Fred. Augustus Palmer Haines, Courtney Nedwill, Robt. Nash, Edward Ellis, Wm. Quarrell, Rich. Dawson, Henry Chas. Wine, Edm. Spooner Machin, Thos. Spilsbury Swinson, Christopher Casper John Kotzé, Francis Patrick Staples, W. Thos. Davies, John Nicholson, Martin Brünges, Thos. Jones, Henry Collins, Joseph Hainsworth, Walter Leaf, Œded Lansley, Wm. Henry B. Clapp, John Lidderdale, Stephen Joseph Manock, Sam. Linley Heald, George Edmund Young, John Andrew Ferris, Thos. Hubert Wadd, Albert Dunning Hunt, Peter Gentle, Thos. Thomson Dick, Fred. Wm. Ricketts, W. Barnes Thomson, Wazir Beg, Jas. Capron Roll, and John Trefourd Jones.

APOTHECARIES' HALL.—Names of gentlemen who passed the Examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, August 2:—Eugene Francis Cronin, Kennington; Adam Fletcher, Bury, Lancashire; Allen Lankester Haynes, Evesham, Worcestershire. The following gentlemen also on the same day passed their First Examination:—Thomas Wemyss Bogg, Louth, Lincolnshire; John Dustan, Jersey; Thomas Holmested, Guy's Hospital; Sidney Thorp, Guy's Hospital.

UNIVERSITY OF LONDON.—MATRICULATION, July, 1860.—The following is a list of candidates who have obtained honours in the respective subjects:—*Mathematics and Natural Philosophy:* Edmund Ledger (Exhibition), City of London School; George Campbell de Morgan, University College; Henry Charles Watson, University College; John Grimes, Wesleyan Coll. Inst., Taunton; John Williams, Normal College, Swansea; Frederick Wm. Richards, Merchant Taylors' School.—*Chemistry:* Alex. Morrison Thomson (Prize), King's College; William Hackney, University College, and James Millington, Cambridge House, Hackney, equal; Edw. Casey, Uppingham Grammar School, Julian Augustus Michael Evans, University College, and Walter Flight, Queenwood College, equal; William Marshall Watts, Owen's College; Frederick Wm. Richards, Merchant Taylors' School; Bushell Anningson, St Bee's College, and Charles Albert Hingston, Portland Grammar School, Plymouth equal.—*Botany:* Frederick Wm. Richards, Merchant Taylors' School; Henry Trimen, King's College School.—*Zoology:* Wm. Hackney (Prize), University College; William Sheldon, Stratford-on-Avon Gram. School; George Edward Shuttleworth, City of London School; Henry Law Kempthorne, Marlborough College; John Tanner, Guy's Hospital.—*Classics:* John George Chancellor (Exhibition), Clare College, Cambridge; Benjamin Renshaw, Stonyhurst College; Augustus Sam. Wilkins, Bishop Stortford Collegiate School; Robert Cardwell, Stonyhurst College;

Edward Ford, Wesley College, Sheffield; John Ryan, Stonyhurst College; Thomas Geo. Osborn, private tuition; Charles Alfred Payton, New College; Francis Frederick Rigg, Wesleyan Coll. Inst., Taunton.

University College, London.—At a Meeting of the Professors and Students of the Medical Faculty, held in the Botanical Theatre of the College, Professor Williamson, F.R.S., Dean, in the chair, the result of the class examinations and competition for prizes at the close of the summer term of the Faculty was announced as follows:—Practical Chemistry. — Professor Williamson, F.R.S. (Dean).—Gold medal, Alex. Bruce, of London; certificates of honour, 2nd, Thomas Foggitt, of Sandhutton, Yorkshire; 3rd (equal), Frederic Fowke, of Ryde, Isle of Wight; Edward Thomas Tibbits, of King's Norton, Leicestershire; George W. Knox, of London; George Walker, of Wigan; Julian A. Evans, of Pinner; and Palemon Best, St Ives, Cornwall. Materia Medica and Therapeutics.—Professor Garrod, M.D.—Gold medal, William Henry Griffin, of Banbury; 1st silver medal, Walker Rickards, of Leicester; 2nd silver medal, William Saul, of Banbury; certificates, 4th, George E. Walker, of Wigan; 5th, Thomas Griffiths, of Carmarthenshire; 6th, Edward Lloyd H. Fox, of Broughton, Hants; 7th, William M. Rogers, of the Mauritius; 8th, James Augustin Greene, of Calcutta; 9th, Alexander Bruce; 10th (equal), George A. Cubley, of Derby; and Reuben T. Warne, of Plymouth. Medical Jurisprudence.—Professor Harley, M.D.—Gold medal, Henry Charlton Bastian, of Falmouth; silver medal, William J. Smith, of Westheath, Hants. Midwifery.—Professor Murphy, M.D.—Gold medal, John H. Hutchinson, of Catterick, Yorkshire; 1st silver medal, Henry C. Bastian; 2nd silver medal, William Saul; certificates of honour, 4th, Edward C. Bury, of Mitchelstown, Ireland; 5th, James Augustin Greene; 6th, George B. Phillips, of Clapham; 7th, William Henry Brotherton, of London. Ophthalmic Medicine and Surgery.—Professor Wharton Jones, M.D.—Silver medal, William Pile, of Barbadoes; certificate of honour, 2nd, John Henry Bridgman, of Bridport. Botany (senior class).—Professor Lindley, M.D.—Gold medal, Thomas Griffiths; silver medal, Richard T. Key, of London; certificates of honour, 3rd, Thomas F. H. Green, of Burnley; 4th, Henry Curtis, of Wellingborough.

University and King's College, Aberdeen.—The Degree of M.D. was conferred on the following gentlemen, after examination, on August 3rd:—George Brotherton Barron, Lancashire; Daniel Beaton, Isle of Wight; Henry Vareke Bindon, Staff Surgeon, Chatham; Henry Billingburst, Islington; Samuel Blakeley, Tyrone; Edw. Hugh Blakeney, Deputy Inspector-General of Staff; Edwin Henry Bolton, Surrey; Miles Vernon Bourke, Limerick; Lewis George Broadbent, Bamburgh; John Candy, Sussex; John Clarke, Assistant Surgeon, 95th Regiment; William Connon, Aberdeenshire; William Coward, South Shields; James Coutts, Aberdeen; William Harry Cooke, Staffordshire; Francis John Corbould, Kent; Thomas Crowther, Yorkshire; Alfred Baker Cutfield, Deal; David Deas, Inspector-General of Hospitals and Fleets; William Deamer, Newcastle-upon-Trent; Oliver Evans, Deputy Inspector of Hospitals, R.N.; Albert Fleming, Sussex; Thos. Balle Forster, Devonport; George Gibson, Chesterle-Street; John Greig, Kincardineshire; Alfred Harvey, London; Leonard H. J. Hayne, Greenwich Hospital; Harrison Hanna, Belfast; George Henry Jackson, Tottenham; David King, Ayrshire; Alfred Kitching, Hull; James Lawrence, Ayrshire; Frederick William Le Grand, Staff Surgeon, R.N.; Thomas Logan, Ayrshire; Augustus Kingston Maybury, Richmond; William Mactyre, London; John Macnab, Lanarkshire; Thomas Mackern, London; James Bell Metcalfe, London; Samuel Smith Millar, Enfield; Alfred M'Kinlay Milman, New Galloway; John Morison, Durham; Michael M'Harg, Co. Antrim; Thomas John Murphy, 60th Rifles; John O'Connell, Cork; Thomas Bacon Phillips, Brighton; John Raines, Manchester; James Rae, R.N., Haslar Hospital; Joseph Rix, Huntingdonshire; Charles Slesser, Aberdeenshire; Charles Somerville, Staffordshire; John Augustus Sommers, Liverpool; Lawrence Spencer, Lancashire; William Stephen, Aberdeen; John Grant Stewart, Greenwich Hospital; William Sutherland, Croydon; John Sutton, Nottinghamshire; John Taylor, London; Thomas George Tebay, London; John Henry Thomas, London; William Thursfield, Shropshire; Charles William Turner, Gloucestershire; John Tulloch, 10th Regiment; Edward Thomas Tylecote, Staffordshire; James Watt, Aberdeen; William Warrwick, Belfast; Thomas Henry Waterworth, London; Samuel Jardine Windowe, H.M. Indian Medical Service.

University of Edinburgh: Degrees in Medicine.—Wednesday, the 1st inst., was the "capping-day" of those graduates of the University who have passed the prescribed examination for the degree of Doctor of Medicine. The proceedings took place in the chemistry class-room, which was, as usual on such occasions, densely crowded. Principal Sir David Brewster presided, and around him were Professors Christison, Syme, Bennett, Crawford, Kelland, Frazer, Traill, Swinton, More, Balfour, Allman, and Laycock. The Rev. Professor Crawford opened the proceedings with prayer. The following are the names of the fifty-seven graduates:—*Scotland:* James Allan, *c*Wm. Anderson, Alex. Balantyne, *b*Andrew Bonthron, Colville Brown, *c*Geo. Cowie, *a*Alex. Dickson, Robt. Erskine, Wm. John Fairbairn, Geo. Hood, Robt. Inglis, *b*Robt. Little, *c*David Lyell, Jas. Nairn M'Dougall, *a*Wm. Carmichael, M'Intosh, *b*Robt. Craig Maclagan, Thos. John Maclagan, *c*James Middleton, *c*Geo. Monteath, John Black Nicol, *c*John O'Neil, Wm. Borwick Robertson, John Ross, Gideon Rutherford, *c*Jas. Saidler, Walter Scott, *c*Robert Stirling Sloan, Robt. Spence, John Jas. Thom, Ebenezer Thomson, Thomas Warden, Peter Plenderleith Whitefield.—*England:* *c*Christopher Jas. Allan, *a*Thos. Annandale, John Broster, Wm. Wilson Cusworth, John Henry Chas. Erridge King, Henry Edward Langford, Wm. Ward Leadam, Wm. Cook Low, *b*Henry Scott, Wm. Scott, Wm. Sheriff, *c*Offley Bohun Shore.—*Ireland:* Wm. Riddall Bell, *c*Samuel Gamble White.—*America:* John Curtis Jones.—*Canada:* John Racey.—*Nova Scotia:* Arthur Moren.—*India:* Valentine Munbee M'Master.—*Port Louis:* Horatio Lazare Beaugeard, John Etienne Arthur Le Déaut.—*Barbadoes:* Wm. John Branch, *c*Wm. Cummings Piggott.—*Trinidad:* *c*Gustavus Chas. Philip Murray.—*Cape of Good Hope:* *c*Alex. Abercrombie, John Philip de Landsberg. [Those who have obtained prizes for their dissertations are marked thus, *a*; those deemed worthy of competing for the dissertation prizes, *b*; those commended for their dissertations, *c*.] At the close of the ceremony of "capping," medals were awarded to Dr Thomas Annandale, Dr Alex. Dickson, and Dr Wm. C. M'Intosh, for their dissertations. Professor Bennett delivered the graduation address, which was chiefly devoted to medical politics.

Guy's Hospital.—Examination of Students in Medicine and its Allied Sciences, July 28, 1860.—Third year's students: E. Beckit Truman, first prize, 40*l*.; F. Mark Cann, second prize, 35*l*.; E. Beckit Truman, the Treasurer's gold medal for Clinical Medicine; F. Mark Cann, the Treasurer's gold medal for Clinical Surgery. Second year's students: Thomas Holmested, first prize, 35*l*.; James F. Stamper, second prize, 30*l*.; P. R. J. B. Minns, third honorary certificate; John Makens, fourth honorary certificate. First year's students: Thomas Stevenson, first prize, 30*l*.; J. St T. Clark, second prize, 25*l*.; J. H. Evans, P. Proctor, W. R. Grove, Joseph Willes, William Murdoch, Henry Hicks, Joseph Lamb, J. A. Taylor, Robert Slade, candidates to whom honorary certificates were awarded (in order of merit).—*Entrance Examination in Classics, Mathematics, &c., Oct.*, 1859: First and second prizes, Wm. Murdoch and T. D. Welch (eq.), 22*l*. 10s.; third prize, A. G. Wilks, 15*l*.; J. St T. Clarke, T. Stevenson, Joseph Willes, F. Woodman, candidates to whom honorary certificates were awarded (in alphabetical order).

A State Asylum for "Criminal Lunatics" is in course of erection at Broadmoor on Bagshot Heath. At present accommodation is to be provided for 400 males and 100 females. The total number of Criminal Lunatics confined in Asylums, Hospitals, and Licensed Houses was, on January 1st, 1860, 731. It is supposed that a merciful administration of justice will reduce this number greatly, so as to bring the Bagshot accommodation up to the demands upon it.

A New College for the Training of Idiots.—In 1857, we favourably noticed a little work by Mr Abbott, M.A., of Queen's College, Cambridge, in which he urged the utility of a Government grant for the education of the twenty thousand idiots, now placed in our lunatic asylums or living at home. Mr Abbott's appeal met with no response, and we are glad to find that, instead of waiting for parliamentary support, he has put his shoulder to the wheel, and opened at Lansdowne House, Greenwich, an institution for the training of idiots of the upper classes. To reclaim the idiot, he must be tutored by a more impartial authority than can be found in the family circle; by a tutor well acquainted with the wonderful cunning by which the idiot evades discipline, and that tenacity of will by which he has all his life shaped his family to his own imperfect ends. We are glad to find that the institution is placed under medical supervision, and that two physicians, Dr. H. Osman, and Dr. J. R. Hancorn, reside on the premises.

The Dust Nuisance Abated.—Experiments have of late been undertaken at Lyons to allay the dust by keeping the streets in a state of perpetual moisture. The agent used is hydrochloric acid, which prevents the rising of the dust by forming chloride of calcium, a deliquescent salt. The method originated with the proprietor of a manufactory of chemicals, who perceived that a terrace of his always presented a moist surface.

The New Species of Man.—M. Payle denies that the Niams-Niams, inhabitants of Sondan, have any prolongation of the coccyx. They are, therefore, improperly called tailed men. These people attach an animal's tail to the place where a tail should be fixed, and this is all their clothing. This it is which has led travellers into mistakes on the matter.

In the Principality of Anhalt-Dessau a new tax has been established on the practitioners of medicine and surgery, a new law on vaccination, and an order for the dispensing of medicines by physicians.

Cholera in Spain.—Recent accounts received from Spain state that cholera extends its mortal influence throughout the southern provinces, Valencia being now the seat of its ravages. In consequence, the steamers sailing from Barcelona thitherward have suspended touching at the first-named port.

Army Mortality Returns.—Mr Freeland has given notice of his intention to ask the Secretary-at-War whether the death-rates in the different regiments of the army, and the causes of death, cannot in future be given in the Registrar-General's quarterly reports. Hitherto the sanitary statistics of the country have been made imperfect by the abstraction of the military portion of the community. There are many obvious reasons which render it highly desirable that Mr Freeland's proposition should be carried out. The army authorities boast, and we believe not without reason, of the accuracy and completeness of their health statistics. The next subject for congratulation, we hope, will be their publication and utilization.

The Tomb of Harvey.—It has been determined by the College of Physicians, with the consent of the next of kin of the illustrious Discoverer of the Circulation, to restore his tomb at Hempstead Church in such a manner as to secure his remains from the desecration and destruction to which they are now exposed.

Another Death from a Dissecting Wound.—M. Dumay, demonstrator of anatomy at the dissecting-rooms of the Faculty of Paris, has just died in consequence of a slight wound received whilst demonstrating. The deceased was much esteemed as a teacher, and had been attached to the school for many years.

Fissiparous Generation.—M. Balbiani has performed further experiments on the subject of fissiparous generation. According to him, it is a very common, instead of a very rare phenomena, as is sometimes thought. To witness its production, however, requires great delicacy of observation and manipulation. He says that he has seen one microscopic animal give birth by fissiparity to more than 2,000 individuals in the course of seventeen days. M. Balbiani counts them by taking one from the number under the microscope, when they have reached fifty. He puts it in water containing none of the animals, and leaves it there until fifty more are formed, and continues thus as long as the phenomenon continues. He does not, however, consider the fissiparity as indefinite; a moment arrives when sexual generation becomes necessary for the transmission of life. A new argument this against spontaneous generation.

CARMARTHENSHIRE INFIRMARY.—A special general meeting of the subscribers of this institution was held on the 1st of August at the Infirmary, for the purpose of electing a Physician and House Surgeon; the former in the room of the late Dr Bowen, and the latter instead of Mr J. L. Thomas, who has resigned. It was resolved, on the proposition of T. C. Morris, Esq., that Thomas Lewis, M.D., be appointed a Physician to this institution, in the room of the late Dr Bowen. Resolved, on the proposition of Mr Hughes, that David Lloyd, Esq., be appointed House-Surgeon and Apothecary, at a salary of 100*l.* per annum. Resolved, that H. Lawrence, M.D., be appointed Honorary and Consulting Physician to this institution, having resigned the office of Physician. In accepting the resignation of Dr Lawrence, the grateful acknowledgments of the subscribers were tendered to him for his valuable, zealous, and unremitting services from the opening of the institution to the present time.

FEMALE PHARMACIENS.—Mrs Mary Fajarde and Mrs Caroline de Matos have lately obtained diplomas as pharmaceutists from the Medico-Chirurgical School of Lisbon. It would appear, according to the *Gazette Médicale*, that these ladies had already been admitted in the same capacity at Oporto in 1829.

INCREASE OF LUNATICS.—The experience of all countries has shown that the numbers of the insane increase so rapidly that the accommodation provided, however sufficient it may at first have appeared, has in a short time been found inadequate. In France, for instance, the number of the insane in public and private asylums amounted, on January 1, 1835, to 10,539; whereas, on January 1, 1854, they had increased to 24,524. In England and Wales the number of pauper lunatics amounted, in August 1843, to 16,764; of whom 3,525 were in county asylums, 2,298 in licensed houses, and 4,063 in workhouses. On January 1, 1859, the number of pauper lunatics had increased to 30,318; of whom 14,481 were placed in county or borough asylums, 2,076 in registered hospitals and licensed houses, and 7,963 in workhouses. It thus appears that in sixteen years the number of pauper lunatics in England and Wales had nearly doubled, and that in 1859 nearly as many were in public and private asylums as were on the roll in 1843.—(Report of Commissioners.)

STATE OF THE PUBLIC HEALTH.—The following interesting paragraph is from the last quarterly return of the Registrar-General:—"The deaths registered in the three months that ended June 30 were 110,878, a larger number than was returned in any previous June quarter (1848-59). The extent to which life was invaded and destroyed by causes that have been described, badness of weather and dearness of food, can be only partially discovered by comparing the mortality with an average derived from seasons both healthy and unhealthy; but it may be stated that the annual rate of mortality last quarter was 2·228 per cent. of the population, while the average of ten previous springs was 2·195. In other words, the mortality was such, that if it had been maintained for a year, out of 100,000 persons 33 would have died in excess of the number to whom a season that could not be represented as healthy, but only of average character, would have been fatal. If the mortality had been at the rate of 17 in 1,000 annually, which is ascertained to be the rule of selected healthy districts, instead of the actual rate (22), the deaths in the whole of England and Wales last quarter would have been 85,283; and 25,595 persons would, when the period had closed, still have formed as many units in the sum of human existence. An excess of deaths which is not decreed by inexorable fate may very properly be termed 'unnatural;' though it is quite true that, only the conditions being different, it is Nature that killeth as well as giveth life. It is a remarkable and interesting fact, if two millions of acres on which the chief towns of England are situated be distinguished from the remaining thirty-five that hold small towns and country parishes, it is found that the rate of mortality on the former (2·305 per cent. per annum) was below the average of last quarter, whereas on the latter the rate 2·155 was above the average. The average rates were respectively 2·346 and 2·028. Although the time may be distant when cities will be as healthful as rural districts, or the inferiority which our English poet ascribed to 'the town' as the handiwork of man become much less apparent in point of salubrity than it is at present, it cannot be questioned that large populations have even now advantages of a nature favourable to health which villages do not possess. The highest attainable health is probably to be sought in a happy combination of both states—*rus in urbe*. The words of an excellent popular writer may prove to be no dream, but a well-founded expectation: he believes that we shall ultimately obtain 'a complete interpenetration of city and country, a complete fusion of their different modes of life, and a combination of the advantages of both, such as no country in the world has ever seen.' But it may be asked, whether it is forbidden by this last expression to accept as a perfect model even Nebuchadnezzar's Babylon, which the distinguished writer himself has extolled."

METEOROLOGY OF THE SECOND QUARTER OF 1860.—"The temperature of the air, barometrical pressure, rain and other elements of the weather, which has been of unusual character, are minutely and skilfully described by Mr Glaisher, in the appendix to this report. He states that both days and nights in April were remarkably cold; those in May were both somewhat warmer than usual; in June both were cold, particularly the high-day temperatures, which were lower than in May, though usually they are higher by seven degrees. April was colder than it had been previously in any year since 1839; and we must travel back to 1821 to find so cold a June. June was colder than May at Guernsey, in Cornwall and Devonshire, and near the sea, south of latitude 53°. The mean temperature of the quarter at Greenwich was 50°·5°, which is less by 2·3° than the average of the same quarter in 19 years. At Greenwich the rain-fall in June was 5·8 in.; as far back as 1815 there is no instance of so large a fall in June. This fall was, however, greatly exceeded at stations south of Greenwich, particularly in Hampshire."—(Registrar General.)

APPOINTMENTS FOR THE WEEK.

Wednesday, August 15.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, August 16.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Home.—2 p.m.

Friday, August 17.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, August 18.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, August 20.

Operations at the Royal Free Hospital, 2 p.m.

Metropolitan Free Hospital, 2 p.m.

Tuesday, August 21.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

The Reformed Roman or Oriental Baths, &c. By James Tucker, M.D. Dublin: Wm. McGee.

Poor-law Reform. By Wm. Gilbert. London: Judd and Glass.

Homicidal Mania. By C. L. Robertson, M.B. Exeter: Wm. Pollard.

NOTICES TO CORRESPONDENTS.

MR G. BROOKS.—No.

CHIRURGUS.—Neither the Medical Council nor the College of Surgeons has any power in such a case. If injury be done, the person sustaining it would have his redress in a court of law.

MR EDWARD L.—Dr Sims, of America, introduced the silver wire suture. Bozeman's method is applicable chiefly to vesico-vaginal fistulas. No doubt the method is very successful in such cases.

A SUBSCRIBER.—We apprehend that Dr Todd carried the stimulating system to its highest point, from which there will be a gradual ebb from henceforth. No man can push the practice more resolutely than he did, and very few will make the attempt. We decline to give an opinion upon the case stated.

B. B.—Certainly.

ALPHA (Leeds).—You are not compellable to comply with the requirement. The interpretation is far-fetched.

A SUBSCRIBER (Cheltenham).—The law was so formerly; but the Medical Act has altered it.

A STUDENT.—1st. Yes.—2nd. Churchill.

AN ALIENIST.—The suggestions are good; but we hold the opinion that modern asylums are much too large, and are, consequently, supervised with difficulty. Even supposing that every attendant on lunatics were required to have a certificate of competency and good conduct as a licence to pursue his calling, that would not supersede the necessity of a strict supervision by the Medical Officer. A certificate might be easily obtained by a very indifferent man.

A COUNTRY SUBSCRIBER.—The number containing the review of Dr Todd's book shall be forwarded.

J. H. S.—1st. We cannot inform you.—2nd. Yes.—3rd. Written and oral.

AN APOTHECARY.—There has not been any proposal to include the Licentiates in the scheme.

DR LYON.—We have not seen the Address alluded to, but it would no doubt give us pleasure to peruse it. With respect to the points mooted in our Correspondents' note, we can only say that we desire to hold an even beam. More than half of the Profession now possess the Doctorate; the honour, therefore, is less exclusive than formerly. We are pressed on all sides. "*Hac urguet lupus, hac canis.*"

E. C. W.—We do not imagine that you would be refused; whether your certificate would give you a legal right to attend is a question we cannot answer, as we do not know the wording of the certificate.

INQUIREN.—If a man binds himself not to practise in a given district, and, notwithstanding, continues to see patients who reside within the district at his house out of the district, sending the medicines within the district to the houses of the patients, there can be no doubt that he is acting dishonourably. Whether he could be punished or not would depend upon the legal interpretation to be put upon the term "to practise." There is no doubt in our mind that the supplying of medicines is exercising one of the functions of, and therefore practising as an apothecary; and we should think that a surgeon would consider such conduct a violation of the agreement. Engagements of this nature cannot be drawn up with too much precision.

*** (Stonykirk).—You would be liable to attend the patient; if you have any objection to give the attendance, the ground of your objection should be stated to the Guardians at the next weekly meeting.

Letters received from R. Millington, S. W. Hudson, &c. &c.

PULVIS JACOBI VER., NEWBERY'S.

GENTLEMEN,—We beg to call your attention to the folllowing paragraph by "*J. Cheyne, M.D., Physician to the Hardwicke Fever Hospital, Dublin, in his paper on the virtues of James' Powder in the Apoplectic Diathesis:*"

"She began a course of James' Powder in the latter end of September: the first night she took only two grains, and every succeeding night an additional half grain, till the dose amounted to twenty grains. She took *twenty grains every night for five weeks*, when she found herself so well that she discontinued the medicine."—"*Dublin Hospital Reports*," *vol. 1. p.* 319.

To secure the dispensing of the *original* preparation, which, for 114 years, has been sold by the Newbery family in St. Paul's Churchyard, it is necessary to prescribe it as "*Pulvis Jacobi Ver., Newbery's,*" otherwise another article (wanting in the best properties, and recommended to be given in a different code of dose, *though called by the same name*), will be substituted for the original medicine. This, of course, cannot but have an effect other than that expected, and will thereby lead the practitioner totally to discard it from his daily Pharmacopœia, as a preparation whereon no dependance can be placed. We hope the above extract will prove that when the genuine medicine is used, faith may be reposed in it.—Yours faithfully,

F. NEWBERY & SONS.

45, St. Paul's Churchyard.

Paper and Envelopes.

A SAVING OF FULL 6s. IN THE POUND.

Cream Laid Note, 2s., 3s., and 4s. per ream.

Large Blue Wove ditto, 3s. 6d. and 4s. 6d. per ream.

SUPER THICK CREAM LAID ENVELOPES, 6d. per 100.

Manuscript Paper, 4s. 6d., and Foolscap, 6s. 6d. per ream.

Bordered Note, Five Quires for 1s.

STRAW Paper, 2s. 6d. per ream.

No CHARGE for Plain Stamping. Dies engraved from 2s. 6d.

White and Blue Demys, and other Wrapping Papers, at a small commission on the mill prices.

Price List post free. SAMPLE packet for six stamps.

CARRIAGE PAID to the country on orders over 20s.

PARTRIDGE and COZENS, Manufacturing Stationers, No. 1 Chancery lane, and 192 Fleet street, E.C.

Neuralgia, Nervous Headaches, Rheumatism, and Stiff Joints Cured, and

Grey Hair Restored to its Natural Colour, by

F. M. HERRING'S PATENT

Magnetic Brushes,

10s. and 15s.; Combs, 2s. 6d. to 20s.

N.B. — The Electro-Galvanic Brushes were formerly made and sold by F. M. H., but the dirt and trouble inseparable from a galvanic apparatus were insurmountable obstacles to their use.

Offices, 32 Basinghall street.

Label Warehouse, Letter-Press, Copper-Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctors' Commons, London, E.C.

H. Silverlock's stock of LABELS for DISPENSING purposes, having been recently revised and enlarged, now consists of upwards of 800 different kinds. Yellow and Green Labels for Drug Bottles, Drawers, &c., at per book or dozen; a Book, containing a selection in general use in Surgeries or Dispensaries, 10s. 6d.

Printed Catalogues of the above may be had, post free on application.

Printing of every description at moderate prices.

Bed Bugs, Green Fly, Red

SPIDER, MILDEW. — GISHURST COMPOUND, patented for killing and keeping away these and other animal and plant pests. Names of eminent authorities who have given testimonials to its success are advertised in the 'Gardener's Chronicle,' 'Cottage Gardener,' and 'Field.' Sold in boxes at 1s., 3s., and 10s. 6d., with reports of trials and full instructions for use, by Chemists and Nurserymen. Wholesale by

PRICE'S PATENT CANDLE COMPANY, LIMITED.

H. Potter, Leech Importer,

In again soliciting a trial of his LEECH AQUARIUM, can now refer to an established reputation for it of four years' standing. Leeches have been kept healthy in it for more than twelve months without any other nourishment. Price, complete with Smyrna Clay, &c., £1 5s.; or a Glass one with oval top, at 12s. 6d.; at the Depot, 65 Farringdon street, London.

Wholesale Warehouse for Assorted Turkey Sponge, and Eau de Cologne in original cases.

H. P., as an Importer of Hungarian and other Leeches, solicits a trial of them; they are not to be excelled for quality and cheapness.

A Priced Catalogue of them and his Medical Herbs sent free to any address.

65 FARRINGDON STREET.

For Correct Family Arms,

CREST, or PEDIGREE, send name and country, and 7s. 6d., to J. LOCK'S City Heraldic Office, No. 2 Old Jewry, E.C., London, and in a few days you will receive a neat drawing of your Arms, &c., in Heraldic Colours, to be engraved on Seal, Ring, or Family Plate. On y parle Français, Italien, Allemand, et Hollandais. Wedding orders executed.

For Family Arms, send name

and county to the HERALDIC OFFICE. No charge for Search. Correct sketch and description, 2s. 6d.; in colour, 5s. Monumental brasses, seals, dies, and diploma plates, in Mediæval and modern styles. Lever-press and Crest dies, one guinea. Illustrated price-list per post.

ARMS, CRESTS, &c.—Gold Medal for engraving Crests on rings or seals, 8s.; on dies, 7s.; arms, crest, and motto, 25s; book-plate, 25s.

T. MORING, Engraver and Heraldic Artist, 44 High Holborn, London.

SOLID GOLD, 18-carat, Hall marked Sard, or Bloodstone RING, engraved with CREST, two guineas; seals, desk-seals, pencil-cases, &c. Send size of finger with orders for rings.

Struve's Seltzer, Fachingen,

VICHY, MARIENBAD, and other MINERAL WATERS.—ROYAL GERMAN SPA, BRIGHTON. Under her Majesty's especial patronage. The Pump-room and Promenade are now open for the 36th Season. The bottled waters are sold at the Pump-room, and by GEORGE WAUGH and Co., Pharmaceutical Chemists to the Queen, 177 Regent street, London, W., and by other respectable houses in London and the provincial towns, where a prospectus with the highest medical testimonials may be obtained gratis.—CAUTION: Owing to the use of Struve's bottles by other parties, please to observe that Struve's name is on the label and red-ink stamp affixed to every bottle of Struve's manufacture.

RUPTURES. BY ROYAL LETTERS PATENT.

White's Moc-main Lever

TRUSS is allowed by upwards of 200 Medical Gentlemen to be the most effective invention in the curative treatment of HERNIA. The use of a steel spring, so often hurtful in its effects, is here avoided: a soft bandage being worn round the body, while the requisite resisting power is supplied by the MOC-MAIN PAD and PATENT LEVER, fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had, and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer,

JOHN WHITE, 228 Piccadilly, London.

Price of a Single Truss, 16s., 21s., 26s. 6d. and 31s. 6d.—Postage, 1s.

Price of a Double Truss, 31s. 6d., 42s. and 52s. 6d.—Postage, 1s. 3d.

Price of an Umbilical Truss, 42s., and 52s. 6d.

Postage, 1s. 10d.

Elastic Stockings for Vari-

COSE VEINS, and all cases of Weakness and Swelling of the Legs, Sprains, &c. They are porous, light in texture, and inexpensive, and are drawn on like an ordinary Stocking. Price 3s. 6d. 7s. 6d., 10s., and 16s. each. Postage, 6d.

JOHN WHITE, MANUFACTURER,

228 Piccadilly, London.

Notice—Behenna and Co.

ACCOUNTANTS, conduct all business entrusted to them, with secrecy, economy, and despatch. Accounts prepared in Bankruptcy and Insolvency. Arrangements made with Creditors. Tradesmen's Books regularly kept. Partnerships and Loans negotiated. Offices, 11 Beaufort buildings, Strand London W.C. Hours from 10 till 4.

Important to Surgeons.—

The old-established and well-known Business of JOHN MILLIKIN, now MILLIKIN and LAWLEY, 161 Strand, adjoining King's College. A change in the proprietorship offers to Surgeons the opportunity of purchasing any kind of Instrument from this well-manufactured stock, which cannot be surpassed in style, quality, or price.

Messrs MILLIKIN & LAWLEY beg to draw the attention of their friends and customers to the superior stock of Mathematical Instruments, their great variety of Cutlery, and the selection of first-class Microscopes, Opera and Race Glasses.

A great variety of Skeletons, Skulls, Hands, Feet, &c., of superior quality, at moderate charges.

Every description of Surgical Instruments made to order, with the utmost PRECISION and DESPATCH.

Surgical Instruments and Cutlery Repaired Daily.

S. W. Silver and Co.'s

OUTFITTING WAREHOUSES, 66 and 67 Cornhill, E.C.—OUTFITS for Australia, India, and China, for Naval and Military Officers, Cadets, Midshipmen, and Civilians; clothing for gentlemen's home use—viz., Naval and Military uniforms and civilian dress of the best material and workmanship; shirts, hosiery, gloves, &c.; ladies' outfits; furniture for camp, barrack, cabin, and colonial use, embracing every variety of cabinet work, canteens, trunks, portmanteaus, &c., suited to all climates.

Manufactory, Silvertown (opposite H.M. Dockyards), Woolwich.

Gluten Bread, Semola,

CHOCOLATE, BISCUITS, CAKES and PATES, for Diabetes, Consumption, Dyspepsia, Asthmas, Invalids, and Infants. Recommended by the most eminent Physicians and Surgeons, and used at the principal Metropolitan and Provincial Hospitals.—John Bell and Co., 338 Oxford street; Thomas Kesting, 79 St Paul's churchyard; Glaisyer and Kemp, Brighton; Alderton, Hastings; Tylee, Bath; Ferris and Co., Bristol; Schacht, Clifton; Randall and Son, Southampton; Proctor and Son, Newcastle; Rendall, Torquay, Exeter, Taunton, and Plymouth; Lofthouse, Hull; Mackay, Edinburgh; and wholesale only of

G. VAN ABBOTT, 13 Basinghall street, E.C.

Fresh Air. — "McKinnell's

PATENT VENTILATOR does that which is the great object in keeping buildings healthy. It rids them of the foul air, and provides for the free inlet of a fresh supply. It is simplicity itself—as, indeed, are most of the Mechanisms adapted to Natural Laws. It can be fitted with ease to carriages, ships, houses, coal-mines, schools, churches, &c. The system, too, is cheap."—'Medical Times,' July 7, p. 11.

JOHN McKINNELL, Patentee, 9 Gloucester terrace, Clarendon road, London, W. Descriptive Pamphlets sent on receipt of one stamp.

Pure Country Milk and

CREAM.—Messrs EDMONDS and BAYNES, OXGATE FARM, WILLESDEN, have received the most flattering testimonials from several eminent Members of the Medical Profession in favour of the purity and freshness of their MILK and CREAM, which they undertake to supply Twice Daily to any part of the West-end. Orders received as above, or at the Office, 16 Marchmont street, Russell square; and at St Petersburgh place, Bayswater, W.

CREAM being now recommended as a substitute for COD-LIVER OIL, Messrs E. and B. beg to inform the Profession that they can supply it in any quantity with punctuality.—A prospectus free by post.

Millikin, late Bigg and Milli-

kin, Surgical Instrument Maker and Anatomical Machinist to Guy's and St Thomas's Hospital, No. 9 St Thomas's street, Southwark, S.E.

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.—July 21st. Cure of Hernia—Invagination.—Mr Wood. (Aug. 5th.) Lithotomy—Lateral Operation—Necrosis of Sternum and Costo-Sternal Cartilages, with Strumous Anscess of Breast.—Mr Fergusson. Plastic Surgery on Face and Neck.—Mr Bowman.

Cure of Hernia.—Mr Wood.

Cure of hernia is a distinguished practice of modern surgery, and the advances and improvements in its practice which have occurred within the last three or four years have been rapid and important, until we have arrived at the last, Mr Wood's operation, which has hitherto proved, under his practice, both permanent in its results and quick in recoveries after operation, patients out and walking about at the end of a fortnight. Even now there are manifestations that this effective and successful operation is not endowed with finality, but that it is destined on many occasions to give way. Advances in simplifying it, and in removing complications attending, have already been some time proposed by Mr Curling and Mr Henry Lee, and changes and modifications are being suggested in daily practice to meet particular contingencies by different surgeons. Several Continental surgeons had proposed and practised modifications for effecting a similar treatment; amongst whom we may name MM. Ragg, Bonnet, Gerdy, and M. Rothmunde of Munich, before the discovery of either Wütze's or Mr Wood's plan. Mr Wood's operation, which we shall presently describe, is a modification of and a very important improvement upon Wütze's. Wütze's was uncertain in its success, which has not been the case with Mr Wood's operation. It is a subject of curious remark, that a curative treatment of hernia has been slowly arrived at, notwithstanding for that object its conditions are good. Cure by ligature of umbilical hernia was practised with invariable success by the writer forty years ago, solving the problem of safety upon inducing adhesion by lymph deposit on strangulation of sac and tissues after reduction of hernial contents. This success is especially manifest in operating upon young subjects, where no alteration, thickening, or degeneration of structures have occurred. It is clear the time has arrived when old cases of hernia will become extinct, and we shall have only those cases resulting from accidents late in life, since all young subjects will be operated upon forthwith for *cure of hernia*. Mr Wood's operation has been attended with almost invariable success.

Operation. — Mr Wood has given a very clear and interesting history of the operation before the Fellows of the Medico-Chirurgical Society, and demonstrated its success by bringing to their notice several cases cured upon whom he had operated, and others have also given descriptions on different occasions, yet, as it is a rather complicated performance, we may be permitted to refer to its details.

The patient, a man about thirty years of age, was placed under chloroform. Laid on his back, and rupture being reduced, the skin was detached from the superficial fascia by introducing tenotomy knife at upper part of scrotum, below lowest part of hernial prominence, and about an inch below the line of the spine of the pubis. An incision was then carried through the skin to the superficial fascia, about an inch in length, which was detached all round by subcutaneous section for about two inches in diameter. When this was effected, the forefinger was introduced by forcibly pushing up and invaginating the fascia as high as the inguinal ring. To effect this, the finger must be introduced well under the skin to invaginate effectively as high as behind Poupart's ligament, and external pillar. A large convex well-curved needle upon a strong handle armed with ligature of thick thread is then guided especially to protect the epigastric and circumflex iliac arteries, by the end of the left forefinger, through the invaginated passage, through conjoined tendon and triangular fascia forming posterior wall of ring, and then through the external pillar of the ring which forms anterior wall of canal, close to Poupart's ligament. The armed needle having been thrust through the pillar and skin, the ends of the ligature were brought through the opening and a central loop in the latter, and the needle withdrawn. The internal pillar was then also reached through the invaginated canal, and pierced with needle in same way, raising the external and depressing the internal pillars, thus humouring the mobile parts to facilitate passage of needle to reach the same opening in the skin of the groin. A cylindrical roll of glass or flattened compress of boxwood, 2¼ in. long by 1 wide, being laid firmly over the canal, the ends of ligature being passed through the loop and tied over the compress, the forefinger should, before fastening, be passed through the external ring to ascertain if the ligatures draw upon the posterior wall. The opening in the scrotum should be tucked well up to, but not within, the external ring. In recent and young subjects, when no adhesions or thickening of parts from callus exist, and tissues are vascular, or when the sac is small, without connection or adhesion with cord, the ligature in such cases may be applied through the fascia and ring, without including sac. Avoiding puncturing the sac in this manner, danger of inducing peritoneal inflammation is avoided. In old cases attachments are formed independent of peritoneum, with scrotum and cord, through which the ligatures necessarily pass, they being all invaginated with the sac and fascia. But after the upper orifice is closed by the ligature, inflammation of peritoneum from the sac is not so likely to happen or take place in the abdominal cavity. In Mr Wood's skilful hands great success occurs, but such might not attend the operation in other hands. The structure of the parts offer considerable facilities for invagination. The loose areolar tissue of the lower surface of the fascia, its synovial character and absence of fat, as also its toughness, compactness, and elasticity, all facilitate that process, giving firm hold to ligatures, and inducing adhesion by lymph deposit, and secure success of operation in such cases. Wütze's, and other plans do not get hold upon the posterior wall of the canal by the ligature, so that the posterior invaginated fascia remains patent for intrusion of future portions of intestine. If to effect this great pressure was obtained, which is often the case, sloughing might occur. In Mr Wood's operation, the skin in process of cicatrization by contraction becomes elevated to the approximated margins of the external abdominal ring. The scrotal fascia, being a highly-organised and vascular tissue, forms a medium of union by lymph adhesion between the tendinous structures and the anterior wall, and also becomes united to the spermatic cord, and thus a kind of valve is formed. The ligatures have a beneficial tendency after operation to counteract the action of the rectus muscle upon conjoined tendon, and consequently upon the inguinal canal; which action tends to draw the posterior wall of hernial sac backwards, and thus dilating it, encourages the growth and early production of hernia by facilitating escape of gut. The action of rectus is thus directly counteracted. The fasciæ, superficial and intercolumnar, so much increased in surface from the dilatation of herniæ, being tough—they also being denuded during operation by laceration and subcutaneous section—adhere from lymph deposit to sides of canal, and thus form a plug in this *cul de sac*. This is rendered complete by the adhesion of sides of dilated external ring, effected by the ligatures passed through them, and through the same holes in the skin, having united them by adhesion of lymph to the invaginated canal. The ligatures likewise being firmly secured over the glass or boxwood cylinder, obtains great torsion, and thus effects by compression a degree of vigour in the union and cicatrices of these loose, flabby tissues, which otherwise could not be effected, as the lymph deposit might degenerate, and give spongy, false, and weak adhesion, especially in old and large-dilated sacs, with future complications in consequence. The compress is allowed to remain from the fourth to the seventh day, dependent upon the vigorous or feeble adhesion in course of formation. The ligatures are not removed so long as they channel away pus or other secretion, and serve like setons to compress and keep alive the action required to give density and firmness to union of sides of invagination. This is especially valuable in the loose conditions of hereditary herniæ. This operation requires little use of knife—no cutting after first incision—and is attended with no scars of skin and fascia after ligatures have sloughed off; the scrotum and parts become natural, and certainly no danger is incurred when performed by a skilful anatomist. Mr Wood has operated successfully upon fourteen cases, some time back, and no doubt has increased that number since. These cases were not selected, but taken as they came to him. In one *varicocele* was present, and the varicocele was also cured by the operation. The patient wore no truss, and was able to lift 100lb. weight, and the side operated upon was quite as strong as the other a few weeks after cure. In another, varicocele occurred on the third day from the operation, necessitating the removal of pad and dressings, which was the only doubtful case. Mr Wood does not now recommend a truss after operation; it tends to produce absorption of newly-formed tissues within canal and ring, which tissues form a plug to prevent return of the hernia. The treatment has been generally a fortnight, and not exceeded three weeks. A light truss might for safety be worn on occasions of great exertion or unusual exercise. Mr Henry Lee has practised invagination of skin of scrotum, with fascia into inguinal ring, by pushing it with the forefinger of left hand up to the inguinal ring. The needle armed with ligature guided by this finger is thrust through the *external* wall of inguinal canal, and out through the skin of the parietes of the abdomen. One end of ligature is left free, and armed needle returned through the same aperture in the scrotum, but pierced and passed through the *internal* wall of inguinal canal. Needle removed, the two ends of ligature are secured by fastening them together, and they are left to ulcerate out.

A successful case of Mr Curling's is recorded in 'Medico-Chirurgical Transactions,' in which, in an omental hernia, he performed a similar operation "by passing the needle through the anterior and posterior walls of the canal."

(August 5th.)—Lithotomy.— Mr Fergusson.

This patient, a man about forty years old, Mr Fergusson had examined a week since. Found urethra large and a good subject for lithotrity, but he was a very irritable subject. He readily acceded to operation for lithotomy, and the lateral operation was performed by Mr Fergusson, attended with a little difficulty in extracting stone. Showing three forceps, and taking up the largest of the three, Mr Fergusson said, "I usually extract the stone with these forceps, which, you see, are large, and have convex wedge-formed blades. This advantage results from their use—you dilate well the neck of bladder and prostate gland by these wedge-like and expanded blades. Their large surface and solidity assist in finding the stone, and on withdrawing them by the semi-rotary movement their wedge-like action brings away the stone with facility and sureness. On this occasion I used the smallest forceps, which obtained firm hold of the stone with facility. On withdrawing them, their force and size were not sufficient to give easy and quick dilatation of the urethra and prostate, and the stone slipped out of the blades. I then introduced a scope, and obtained firm hold of the stone between it and my finger, but it slipped away again. The dilatation after these three attempts became complete, and upon introducing the largest forceps you saw I easily withdrew the stone. Another advantage of large forceps is, they cover well the stone, and prevent rough sides, as in this instance, from coming in contact with soft parts during extraction. For this particular stone these large forceps are exactly suitable: you see," showing the stone in the blades of the forceps, "they nearly cover its circumference." From having recommended lithotrity, Mr Fergusson, no doubt, concluded that the stone was small. It was a circular stone, of more than medium size, flattened on both sides. To hear a great operator expose a source of impediment and difficulty in surgical operation, is always profitable. The knife used on this occasion shut like a pocket-knife, had a long spare blade, straight back to point, cutting edge slightly convex from point for about two-thirds of its length, and then had a slightly concave sweep to heel; a construction giving it great facility and freedom for withdrawal with a cut, the line of action corresponding with the axis of external incision; its length giving power and freedom of use, and distal convexity rendering it light, and able to give unity to external and internal incision.

Necrosis of Sternum and Costo-Sternal Cartilages, with Strumous Anscess of Breast.

Suppuration and abscess on the breast occurred to this patient about five years since, evidently

having a strumous character, leaving sinuses. The patient being so irritable, she could not bear introduction of a probe, chloroform was administered. The upper sinus, which implicated only the soft tissues between the skin and bone, and which Mr Fergusson freely opened by incision, guided by finger, would no doubt quickly heal. The lower sinus communicated in a burrowing manner with others in different directions, and also with the sternum and costo-sternal cartilages. It was traced with probe, and laid freely open. In the diseased tissues a small spicula of necrosed bone, superficially situated, was removed. Upon dilatation, the sternum was rough and denuded, denoting necrosis of bone. Mr Ferguson introduced a scope, and gouged out a portion of dead bone. This small spicula acting upon degenerated tisssues having low vitality, had long prevented a healing process. The spicula of bone being removed and a free opening made, would induce reaction, and throwing off remainder of caries, if there be any, these free incisions and scraping of bone would act by stimulating a healthful process. Usual dressings applied.

PLASTIC SURGERY ON FACE AND NECK.—MR BOWMAN.

A patient of Mr Bowman's, a woman about forty-five years of age, was introduced, to have further plastic operations performed upon face, eye, mouth, and neck. She had had repeated operations done already of an interesting kind, to restore lost, and repair deformed and destroyed parts. The series of operations had commenced about five months since. It was a most extraordinary case; the whole of the left side of the woman's face having been destroyed by burns, including left eye, quite gone—tissues and integuments of the lateral part of the head and face, the chin, lips, and front of the mouth entirely lost, exposing alveolary processes, fauces, and tongue, and great destruction of parts about neck and throat. This state had induced Mr Bowman, at different times, to perform a series of complicated dissections and manœuvres on all the injured parts within reach, to accomplish restoration and renewal, as well as removal of parts, by plastic means. It appears that by dissecting portions of cuticle and integument from the forehead, Mr Bowman had obtained required flaps, which he transformed to the eye and other parts of injured face, keeping their connection, and thus obtained restoration, or renovation of lost tissues and integuments, and a great mitigation of deformity almost revolting to witness. The same plastic means were practised in transposition of skin and tissue from right side of the face and neck, to be readapted to form the outline of the chin and lips. By bringing the dissected integument and skin into the places required; for example, from the neck, to form plastically, the intended lips, was brought into contiguity with the mucous membrane of the mouth. The mucous membrane had its margin converted into free edges, by dissecting their surface; union being thus obtained by adhesive lymph effusion. The great restoration of destroyed tissues and lost parts, and the amelioration of deformity, were a pleasing and extraordinary demonstration of the results of plastic surgery, and of the great patience and skill displayed in these successful operations. It appeared that slits, scarification, and incisions here and there, especially upon external angle of the right eye, and left angle of mouth—the incisions to obviate contractions of cicatrices, &c.—had to be occasionally done during treatment.

THE SPIRIT OF THE PERIODICALS.

We extract the following article on *Foreign Bodies in the Bladder* from the 'Journal of Practical Medicine and Surgery:'

"On the 26th September, 1859, a woman, aged forty-nine, suddenly experienced exquisite pain originating in the presence of a calculus in the urethra; this concretion was crushed, and partly extracted, the remaining fragments being expelled with the urine. A month after, the same sudden pains recurred, occasioned by retention of urine, which was produced by a tuft of hairs agglomerated and united by a soft substance, forming a flat mass of ⅔ inch in diameter, and rather more than ¼ inch in thickness, covered with an earthy crust. A fortnight after, the permanent symptoms of stone were present; and in the space of a few weeks they increased to such a degree, that life became insupportable. Admitted into hospital on the 28th April last, the woman, already exhausted by pain and sleeplessness, underwent an operation on the 3rd May following. A large and friable stone was seized and crushed; but in closing the lithoclast to withdraw the calculus, M. Civiale observed a larger and more resistant body, which he did not attempt to pulverize. Having ascertained that it did not project beyond the instrument so as to injure the duct, he easily extracted the substance, which proved to be a small human tooth. No accident ensued, and many fragments of calculus were subsequently expelled. On the 8th May, large fragments presented themselves at the internal orifice of the urethra, and were extracted. On the 16th, two other teeth were withdrawn with a large amount of stony concretions. On the 14th, the excretion of water was painful; M. Ciavale removed, with a peculiar lithoclast, a portion of bone, another tooth, and a mass of stony fragments, which, by its volume, would have been alarming, were not the dilatability of the female urethra so well known. From that time, the pains ceased, and the patient's health has been restored with extraordinary promptitude.

"M. Robin examined the bones, hair, and teeth extracted from this woman's bladder, and he recognised that they were the remnants of a fœtus proceeding from a cyst in communication with the urinary reservoir.

"In other cases, hair found in the bladder comes from the pubes and has ascended through the urethra. M. Civiale performed operations on eleven patients, in whose bladder were found pieces of straw and grass, peas, kidney-beans, barbs of corn, cotton, &c. The most curious of these cases refers to a man, with a large calculus, which had formed around a medallion an inch long and ½ inch broad. This man informed M. Civiale, that, being intoxicated, he had fallen asleep near a wash-house, and that the laundresses had introduced into his urethra the medallion which one of them wore. The skilful surgeon remarked that when a foreign body has remained any time in the bladder, the urine instantly presents a predominance of phosphatic salts, a circumstance which explains the rapid formation of the calculous shell which envelopes the extraneous substance.

"In all cases of the kind, lithotrity is the only rational method of treatment; but its application requires much precaution, careful tentatives, and sometimes peculiar instruments. M. Civiale was compelled to resort to many successive attempts, in the case of a patient who had inserted into his bladder the handle of a brush three inches long, and to divide this body he was obliged to use a lithoclast, with sharp blades like those of pruning-shears. In another instance, in which the body introduced was the glass tube of a thermometer, the tube was seized by one of its ends, but it broke, and M. Civiale, after having extracted a fragment one inch long, was obliged to remove in succession sixteen distinct pieces proceeding from the broken portion.

"It will be readily understood that most persons, belonging to the category we have just described, are disposed to conceal the presence of a concretion which betrays their vicious practices; but instances of dissimulation of a calculous affection must be very rare, and in this respect the following case, which M. Nélaton lately related at his clinical conferences, appears to us both instructive and eccentric:

"A boy from ten to twelve years of age, in the apparent enjoyment of good health, complained of vague intra-articular pains. His medical adviser, a very enlightened man, believed however his statements, and instituted various medications which proved unavailing. The child continued to complain, but nothing could be detected of a nature to justify his affirmations. The physician then suspected the presence of gouty arthralgic diathesis; he analyzed the urine, which was of a higher specific weight than in health, and contained uric acid. The child was placed under the influence of alkaline treatment, and every day concretions were expelled from the urethra, and collected with scrupulous care by the patient's mother. M. Nélaton exhibited these substances to his auditory. They were of all shapes and all origin—pieces of ashlar, mortar, silex, river-sand—but in no wise did they resemble calculi.

"This would assuredly appear an inexplicable and impossible fraud on the part of a lad of eleven. Nevertheless, he had contrived, every now and then, to introduce into the urethra one of those fragments, and he called his mother to see them issue with the urine. All the persons around the alleged patient believed and still believe in his candour, and in the virtue of lithontriptics. M. Nélaton respected this belief, but he made a memorandum of the case, to illustrate the importance of the practitioner being on his guard against similar attempts at imposition."

Mr WEST, of Birmingham, continues in the 'Dublin Quarterly Journal' his articles on *Syphilitic Stricture of the Œsophagus*. We quote the case reported:

"Mary H., widow, aged twenty-five, was admitted into the Queen's Hospital, July 12th, 1859, with secondary syphilitic rupial crusts and ulcerations over the face and legs. The general health was extremely bad, and she was much emaciated. She stated that she contracted sores from two to three months before the rupial crusts appeared, but that she underwent no treatment for them, and was unaware of their nature until a week before admission, when a surgeon who examined her declared them to be syphilitic.

"On admission, poultices were applied to the crusts, and stimulants and tonics, with liberal diet, were given internally. In the course of a week she rallied, and improved in strength and appearance; the crusts cleared off, and displayed the usual excavated circular livid ulcers of secondary syphilis. Dry calomel fumigation was ordered, and used on four successive days, when, its effects having become evident on the gums, it was discontinued. For ten days from this time there was considerable improvement in the appearance of the sores; some of them filled up, and all took on a more healthy action; however, there was no corresponding improvement in her general condition; her appetite was very bad, and her debility seemed to increase rather than diminish. Wine, with beef-tea, eggs, and arrow-root, were allowed daily in addition to the ordinary hospital diet; decoction of bark and nitric acid were given also.

"In the beginning of September the sores were looking very unhealthy and callous, and the application of nitric acid to them was therefore tried, and followed up by charcoal and linseed-meal poultices. Under this treatment the sores cleaned slightly, but showed no tendency to cicatrize. Iodide of potassium in 5-grain doses, and a mild stimulant lotion of liquor sodæ chlorinatæ were ordered on the 7th of October, and continued until the 15th, when it was found necessary to suspend them in consequence of violent diarrhœa having set in, and a new rupial sore of large dimensions (3 inches by 1) having formed on the right ala nasi. Acetate of lead and opium soon checked the diarrhœa; but the ulceration of the nose and cheek having extended, it was again necessary to resort to the use of nitric acid and charcoal poultices. The slough having cleared away, iodide of potassium in smaller (3-grain) doses was then tried; but its tendency to produce diarrhœa having again manifested itself, it was discontinued. Bichloride of mercury in small doses was then had recourse to, but without avail; she became more debilitated; the sores increased in size and number, in spite of the oft-repeated application of nitric acid, and of every kind of astringent and stimulant preparation that could be thought of. Difficulty in swallowing food and medicines began to be noticed about the end of December; it attracted little attention, however, as her general condition was so bad as to preclude the hope of satisfactorily treating any affection of the fauces or œsophagus to which it might be owing. Constant exhibition of stimulants and fluid nourishment was necessary; ether and ammonia were in requisition every few hours, to ward off the fatal termination which was anticipated, and even thought to be imminent every day during the month of January, 1860. In this fearful state, unable to leave the hospital, or even to have her bed changed, she lingered on till the 4th of February, when death put an end to her sufferings.

"The post-mortem examination, made 45 hours after death by Dr Walker, revealed the following condition :—The body was that of a small emaciated woman, whose legs were drawn up to the abdomen, in consequence of the contraction caused by cicatrization of ulcers about the knees, and whose face, legs, and trunk presented numerous patches of rupia in various stages, interspersed here and there with cicatrices of old spots of ulceration. The nose was almost destroyed by a recent ulcer, and the back was the seat of a large sloughing bed-sore. The head was not examined, in consequence of vermin swarming about it.

"The heart was healthy in texture, but the foramen ovale would admit a goose-quill ; weight, 6 oz.

"The lungs were healthy.

"The œsophagus presented a reddish, livid erosion of the mucous membrane at its lower part for about two inches, more especially just above the cardial orifice of the stomach. There was no deep ulceration or marked constrictions, but considerable fibrous deposit in the submucous tissue, which apparently diminished the calibre of the canal immediately above the chief erosion.

"The liver was pale and fatty, but not hypertrophied. The knife became very greasy on a section being made ; weight, 43 oz.

"Spleen normal, 4 oz. ; kidneys anæmic, each 3 oz. The supra-renal capsules presented a limited deposit of grey exudation in the central cavity.

"The mucous membrane of the *stomach* was throughout softened, and an irregular shallow ulcer, the size of a shilling, was formed on the lesser curvature.

"There was slight congestion and abrasion of the vaginal surface of the cervix uteri ; but the uterus was otherwise normal, and the ovaries were free from disease.

"Here, then, is another instance of the existence of ulceration in a canal which has hitherto been looked upon as more free from the influence of the syphilitic poison, and less frequently the seat of its organic lesions, than most of the other parts of the body. Its extent and intensity were not so great as to seriously impede the passage of fluids ; but solid nutriment was, during the last five weeks of the patient's life, taken with considerable difficulty, and it is more than probable that, had the reparative powers of her constitution been greater, the ulcer of the œsophagus would have shown a tendency to cicatrize, and, from its cicatrization, diminution of the calibre of the canal would almost inevitably have resulted.

"The situation of the ulceration at the lower part of the œsophagus, close to the cardial orifice of the stomach, is remarkable, particularly as, towards the same end of the tube, a similar condition had evidently existed in the case of Jane M., previous to the stage of constriction coming on. The ulcer found in the stomach may most likely be referred to the same origin as that in the œsophagus, though smaller in size, and its appearance was very similar ; it was altogether distinct in character from that which is termed the 'perforating ulcer,' and more nearly resembled that form of hæmorrhagic erosion which is found in cases of death from burns.

"The absence of tubercular disease of the lungs, and, in fact, the non-existence of any visceral lesion whatever, that would be sufficient to cause death, further assist us in arriving at the conclusion that to syphilitic cachexia, together with ulceration of the œsophagus and stomach, which must be regarded as phenomena of that condition, the fatal termination in this interesting case must be assigned.

"The girl, H. P., whose case I related in my last paper on this subject, is still living, but her condition is daily becoming more perilous. She is very irregular in her attendance at the hospital, and declines to become an in-patient. I have lately, at the suggestion of Mr Acton, who was kind enough to express an interest in the case, given much larger doses of iodide of potassium than I had previously exhibited, as much as twenty grains being now given for a dose, but its effects cannot be clearly determined from the cause before stated."

The 'Lancet' opens with a continuation of Dr Brown-Sequard's Lectures. The present paper treats of the *Prognosis and Treatment of Myelitis, of Spinal Meningitis, and of Spinal Congestion.* We extract it :

"*Prognosis of Paraplegia due to Myelitis.*—Myelitis, either chronic or acute, has long been considered as an almost incurable disease. It is true that in a very acute form this inflammation is almost always fatal. Not so, however, as regards the subacute or chronic myelitis if it exists in the lumbar or the dorsal regions, where this inflammation is most frequently located. Chronic myelitis is an affection of slow development, and still slower progress. When not properly treated, it extends gradually upwards, and slowly causes a more and more complete paraplegia ; but it destroys life only after several years of paralysis. I have known a case in which it has lasted twenty-one years. When properly treated, myelitis is very frequently stopped in its progress, and sometimes an almost complete cure may be obtained. Out of nineteen cases now under my care in private or in hospital practice, there are three in which there has been rather an increase of the affection than an amelioration ; two in which the amelioration approaches to a cure ; seven in which there is a marked amelioration, though less than in the preceding ; two in which, after a decided improvement, a relapse has occurred ; and five in which the treatment has not yet been employed for a sufficient time to lead to any opinion as to its efficacy.

"From these facts, and also from the effect of the treatment in many cases under my care, or that of several medical men during the last few years, it results that the prognosis of the chronic, or even the subacute, form of myelitis should be considered as much less grave than it has been until lately. However, it is true that when the affection is altogether stopped in its progress, and when many of the symptoms have ceased to exist, the paraplegia remains, although the inflammation of the spinal cord may be cured. The patient can command the motions of his bladder ; he may walk as much and almost as fast as he could before he was attacked with myelitis, without feeling fatigue ; but however great may be the amount of his motor power, he cannot *direct* his movements so well as can be done by even a weak but healthy man. This is due to the fact that the alterations caused by myelitis in the spinal cord are almost irreparable.

"*Treatment of Chronic Myelitis.*—1. The first and most important rule is to diminish the congestion of the spinal cord. For this purpose the various following means ought to be employed :—

"1st. If possible, the patient should never lie on his back. Whether at night or in the daytime, if he lies down, he ought to place himself on the right or the left side of the body ; and, if he can, he should even lie flat on the abdomen, so as to diminish by the effect of gravitation the amount of blood in the spinal cord. At the same time, his arms and legs ought to be covered with flannel, and placed on a lower level than that of the spine, for the purpose of attracting blood to them. If the patient cannot avoid lying on his back, he must have a hard bed, or at least not a feather-bed. I need hardly say that a water-bed will be necessary if there is any appearance of ulceration or sloughing on the nates or the sacrum.

"2nd. Applications to the spine of those means that may attract blood outside of the spinal canal should be made as often as possible. Perhaps the best means is the application of a hot douche to the spine. The water ought to fall from at least four or five feet through a tube three-quarters of an inch or one inch in diameter. Its temperature ought to be between 98° and 101° Fahr., and the application should be continued two or three minutes and repeated every day. The cold shower bath may also be employed with advantage, if, immediately after it, the spine be rubbed with a warm flannel, so as to produce a dilatation of the bloodvessels of the skin and muscles of the back.

"3rd. Dry cupping applied daily, alternately on the various parts of the spine, will prove of service if its use be persevered in for a long while.

"4th. The applications of blisters, moxas, cauteries, &c., may certainly be useful ; but the pain they give, and the danger of their being the origin of a slough, ought to be taken into great consideration. I generally prefer employing the hot douche and dry cupping. However, where the myelitis is caused by a caries or some other organic affection of the spine, applications of the actual cautery, or of moxas, and other local revulsives on the diseased spot of the spine, are to be preferred to the simpler means (hot douche, cupping, &c.)

"5th. Amongst the remedies to be employed internally, the most active are those which have the power of diminishing the congestion of the spinal cord. The two which seem to be most powerful in this respect are belladonna and ergot of rye. Experiments upon animals have shown to me, in the most positive manner, that these two remedies are powerful excitants of unstriped muscular fibres, in bloodvessels, in the uterus, in the bowels, in the iris, &c. Both of them dilate the pupil ; both are employed with success to produce contractions of the uterus ; but each of them has more power in certain parts than the other, so that we find belladonna acting more than ergot on the bloodvessels of the iris (which is the principal cause of the dilatation of the pupil)—on the bloodvessels of the breast (which is the principal cause of the cessation of the secretion of milk)—on the muscular fibres of the bowels (which is the mode of its action in cases of strangled hernia)—on the sphincter of the bladder (which is one of the causes of its success against nocturnal incontinence of urine), &c. ; while, on the contrary, we find that ergot acts more than belladonna on the muscular fibres of the womb, on the bloodvessels of the spinal cord, &c. We cannot give here the proof of the exactitude of these assertions on the mode of action of these two remedies, but we must at least answer an objection which probably will arise in the mind of many persons. It will be asked—How is it that, of two remedies that are able to excite contractions in smooth muscular fibres, one produces them more in one place, and the other more in another place ? The answer to this objection is indeed very simple. The excitability of smooth fibres, as well as that of striated muscles, varies exceedingly in different parts of the body. An exciting agent (whether galvanism, cold, heat, or belladonna and ergot of rye) will produce powerful contraction in some places, and hardly any in other places. The smooth fibres of the uterus contract more than those of the bowels or the bladder, and less than those of certain bloodvessels when stimulated by galvanism ; the smooth fibres of certain bloodvessels contract more than those of the uterus under the excitation of cold ; still more, the bloodvessels of the cerebral lobes and of the face, which contract so much when their nerve (the cervical sympathetic) is irritated, contract but very little when excited by belladonna and ergot, while these two excitants produce powerful contractions in the bloodvessels of the spinal cord.

"Not only have I seen the diminution in the calibre of bloodvessels of the pia mater of the spinal cord taking place in dogs after they had taken large doses of belladonna or ergot of rye, but I have also ascertained that the reflex power of the spinal cord (most likely as a consequence of the contraction of bloodvessels) becomes very much diminished under the influence of these two remedies, which in so doing act just in the opposite way to that of strychnine.

"Led by the knowledge of the above facts, we have employed belladonna and ergot of rye in cases of paraplegia due to a simple congestion or a chronic inflammation of the spinal cord and its meninges, and we have obtained a greater success than we had dared to hope for. Whatever be the value of our experiments on animals as regards the mode of action of these remedies, it is now certain that they have really a great power in diminishing the amount of blood in the spinal cord and its membranes. It is very well known that many French physicians, especially Bretonneau, Payan, Barbier, and Trousseau, have for many years employed with success belladonna and ergot of rye in cases of paraplegia. Of course we do not claim to have been the first to make use of these remedies in paraplegia, any more than we claim priority as regards employing strychnine in various forms of paralysis. But we claim to have pointed out, as clearly as we could, in what cases of paraplegia strychnine or belladonna and ergot of rye are to be employed or avoided. To indicate this distinction is the principal object of these lectures.

"In the beginning of the treatment of chronic

myelitis, we usually employ ergot of rye alone internally, and belladonna externally in a plaster applied to the spine, over the painful spot. The dose of ergot, when the powder is used, which is almost always the case, is at first two or three grains twice a day; gradually the dose is increased until it reaches five or six grains twice a day; and in a few cases we have given eight grains twice a day. We do not think it is necessary to make use of the very large doses employed by M. Payan. The belladonna plaster applied to the spine must be a very large one, four inches wide, and six or seven inches long. If there is no amelioration in a few weeks, we give the extract of belladonna internally in doses of a quarter of a grain twice a day.

"When we find that the patients, after six or eight weeks of treatment by ergot of rye and belladonna, do not get better, we give iodide of potassium in doses of five or six grains twice a day, in addition to the preceding remedies. When there is any reason to suspect that there is a degree of meningitis together with myelitis, we begin at once the treatment by the iodide of potassium with the ergot and belladonna.

"II. The second rule of treatment of myelitis is to prevent the formation of sloughs, or to cure them when formed, and to prevent other alterations of nutrition in the paralysed parts.

"1st. Ulcerations and sloughs on the nates, the sacrum, or other parts, may be prevented or stopped in their development, if they have not acquired a great extent, by very simple means, which I have found perfectly successful in experiments upon animals. Led by the view that sloughs are chiefly due to an irritation of the vaso-motor nerves, producing alterations in the nutrition of certain parts of the skin, I have thought that alternate applications of cold and heat to the parts where there is a threatening of sloughing, by acting upon the bloodvessels, so as to produce in them considerable contractions and dilatations, might prevent the effects of the irritation of the vaso-motor nerves in the spinal cord; and the success I have obtained shows that this view is probably quite right. The means I propose is the alternate application of pounded ice in a bladder, and a warm poultice; the ice to be left ten minutes, or even less, and the poultice an hour. It is in cases of fracture of the spine, followed by myelitis, that I have employed these means; but hitherto only on animals. I hope surgeons will soon decide what is the real value of this means in man.

"2nd. To prevent the alterations of nutrition (œdema, atrophy, &c.) in the paralysed limbs in myelitis, the best means are, shampooning, applications of galvanic currents, and the use of the flesh-brush. When there is no œdema, a warm foot-bath every night is of service in those cases where the feet are very cold.

"3rd. The morbid alterations in the kidney and bladder may be prevented or alleviated by the exhibition of liquor potassæ, turpentine, opaiba, tolu balsam, &c. We need hardly say, that if nephritis or cystitis occur, it should be treated energetically.

"4th. The bowels must be kept open, on account of the increase of the congestion of the spinal cord that results from constipation. The narcotics which produce constipation and congestion of the spinal cord, especially opium, should be avoided; and, in case of sleeplessness, hyoscyamus, conium, lactuca virosa, and cannabis indica, are amongst the remedies that should be resorted to. We usually prefer hyoscyamus.

"III. As regards other remedies, we sometimes give cod-liver oil in those cases where rheumatic pains seem to exist. As regards dietetic rules, nutritious food, and a little wine and ale (*not containing strychnine*), are to be prescribed. The patients should take moderate exercise in the open air.

"*Prognosis and Treatment of Paraplegia due to Chronic Meningitis.*—The prognosis of this affection is nearly the same as that of chronic myelitis, with this difference, that the paralysis may be more completely cured after a meningitis than after a myelitis.

"The treatment of chronic meningitis is almost the same as that of chronic myelitis, with the following exceptions:—1st. Blisters ought to be the principal means employed in cases of meningitis: every fortnight a new one should be applied while the preceding one is drying up. 2ndly. Iodide of potassium, in doses of six grains twice a-day, is to be preferred to ergot and belladonna in cases of chronic meningitis. If there are signs of considerable effusion, diuretics should be used in conjunction with the iodide.

"*Prognosis and Treatment of Paraplegia due to a Congestion of the Spinal Cord and its Membranes.*—This affection is much less fatal, and much easier to cure completely, than myelitis or meningitis. However, when the paraplegia due to congestion is of long standing, it is almost as difficult to cure as paralysis due to meningitis.

"The same general rules are to be followed in the treatment of congestion as in that of inflammation of the spinal cord and its meninges. Internally, at the same time, ergot of rye, belladonna, iodide of potassium, and sometimes diuretics, should be used. Externally, the cold shower-bath should be employed rather than the hot douche, or any other revulsive; and if the shower-bath cannot be borne, the alternate application of two sponges, one with very cold water, the other with hot water, should be made every morning along the spine."

Mr Hilton's Lectures on *Pain and Rest* are continued in the same journal. Dr Patrick Fraser contributes an article on *Stimulation versus Depletion*. As there is a certain literary interest in the article, we quote the more important portion of it:

"First Epoch.—(*From the earliest ages down to the time of Hippocrates.*)

"Bleeding was practised by the ancients under various impressions, such as that its effects were evacuant, revulsant, derivative, alterative, excitant, depressive. Prolix disquisitions on these various supposed powers prevail in their writings, and the fact of these opposite powers having been attributed to venesection exerts no small influence on the practice of medicine in the present day.

"Our information as to the origin of bloodletting is imperfect, owing to the dark traditions of the ancients.

"The Egyptians disapproved of bleeding, but the following is the version by that people of its rise:—It was observed that when the hippopotamus had a headache (whether after an undue potation is not stated), he emerged from his watery bed, and performed the operation of bleeding by striking his ponderous foot upon some convenient sharp stone, thereby causing a flow of blood, which he arrested at pleasure by a pledget of mud. This interesting animal has thereby the credit of having been the earliest surgical operator, as well as having taught mankind the value and use of styptics.

"Pliny (Hist. Nat., viii., 25, 26), in a more elegant fiction, states: 'The sea-horse, when too full of blood,' scratches himself on rose-bushes, and then staunches the flowing of the blood by rolling in the mud.' Our rose-bushes must have deteriorated in their strength of prickles, for very few of the present day would much affect the hide of the modern hippopotamus. But however this may be, it is clearly recorded, like all other matters of ancient history, that Podilarius, one of the sons of Æsculapius, practised venesection A.C. 1134, and that the first bleeding was made on the daughter of King Dametus. The fee was liberal, being not only the patient in marriage (who, we are bound to believe, was both young and beautiful), but the Chersonese to boot for a dowry.

"From the earliest period of our race, the nasal and catamenial fluxes would be observed, and noticed as often beneficial; and down to the present time there have been practitioners who have taken spontaneous bleedings as indicative of the need for general depletion. We are therefore justified in concluding that artificial means of relief would be resorted to—if not, like the polished Tahitians, by opening a vein, at least, like the rougher natives of Guinea, by plunging a knife into the flesh at hap-hazard.

"Arriving at more authentic periods, we know that Pythagoras (B.C. 580) disapproved of bleeding; that Hippocrates (B.C. 420) speaks of it as a practice well known, and that he himself practised it; for the name Anaxion is given as that of one of his patients who was bled on the eighth day of a pleurisy. This being the only recorded case in which bleeding was practised by Hippocrates, is by many persons considered a proof that he did not often bleed. This conclusion is not supported, however, in other parts of his writings, for this truly wonderful man gives repeated and careful directions as to the veins to be opened, and the manner of the operation; and he gives a specific recommendation to practise it in cases of apoplexy, pneumonia, and pleuritis; and also advises that the bleeding from wounds, except those entering the 'ventrem internum,' should not be suddenly arrested, as by its flowing inflammatory action might be lessened.

"In Sprengell's translation of the 'Aphorisms,' Sect. 10, Aph. 29, we have the ancient oracle speaking thus: 'But if a violent fever should require bleeding, to do it in its full force and height would be to kill the patient; we must stay, therefore, till the fever abates, and not bleed so much at once, but repeat it rather.' This axiom is repeated by Celsus. At Sect. 10, Aph. 23, he again speaks: 'Letting blood by the opening of a vein is no new thing; but to do this upon account of every disease is entirely new.' Verily the oracle spoke then as would truly now apply.

"Second Epoch.—(*From Hippocrates to Paracelsus.*)

"In the work of M. Freteau on 'Bloodletting,' there is a brief account of the successors of Hippocrates, of which, with some alterations and additions, we now give an abstract.

"The most distinguished disciples of Hippocrates—namely, Diocles and Praxagoras (B.C. 340—practised venesection; while Chrysippus and Erasistratus denounced the practice; and shortly afterwards Cleophantes employed wine extensively as a remedial agent. We may suppose, therefore, that at this remote period the discussion began, and has continued with varying fervour to our own time, as to the respective merits of depletion and stimulation in the treatment of disease.

"The successors of these physicians departed into the different countries under the Roman government, and disseminated and supported the doctrines of their masters according to their adherence. For instance, Asclepiades (B.C. 90) rejected all evacuant remedies, especially bleeding; while Themison approved of its moderate use. This latter passes as the first physician who employed leeches, although there is mention made of their use so early as B.C. 140. Celsus (A.D. 10) bled children, old men, and pregnant women. Aretæus (A.D. 90) speaks of venesection, leeching, and blistering. Galen (A.D. 131) declared himself an adherent to the principles of Hippocrates, and bled frequently: his chief indications were to evacuate the redundant blood in a plethora, or as a revulsant; and he appears to be the earliest writer to specify the exact quantity of blood to be extracted in special cases of disease; and in certain cases he bled to the extent of inducing 'deliquum animi.' About the year 280, Severus, Antyllus, and Apollonius practised ateriotomy and scarifications. The successors of Galen pursued his mode of treatment. For example, Orabasius, in 360; Ætius, in 540; Alexander of Tralles, in 570; Paul of Ægina, in 670; Mesue, Serapion, Rhazes, and Avicenna, during the ninth and tenth centuries. The latter states that the usual quantity of blood in a man's body is 25lb., and that a man may lose 20lb. at the nose 'and not dye.' Was this ever proved? Avenzoar, Averrhoes, and Albucasis, in the twelfth century; and the doctrines of the schools of Salernum, A.D. 1000; of Montpellier, A.D. 1200; of Paris, A.D. 1300; also Gui de Cauliac, were Galenistic. The sect of Chemists appeared A.D. 1400, and their influence rather retarded the progress of the healing art, and the act of bleeding was reprobated. Further information upon the opinions of the ancients on venesection will be found in an excellent commentary in Adams's 'Paulus Ægineta,' p. 319.

"In the works of all the men whose names have been mentioned, although bleeding is more or less recommended, then, as now, long and angry disputes occurred as to the prophylatic and curative powers of bleeding, as well as to what veins or arteries should be opened in certain diseases. One and all, however, agree in the necessity for care in the adoption of venesection, and that so powerful a remedy should be employed only 'when the disease is of a strong nature, the patient in the vigour of life, and the strength unexhausted.' Celsus goes so far as to say, that 'to bleed a man in the first stage of fever is to

kill him;' and Galen takes the precaution to give lists of diseases in which venesection should never be practised, as follows: cacoehymia, plague, dysentery, low fever, intermittent fever, serous apoplexy, dislocations; and in those in which it should be only rarely practised—viz., fractures, renal calculi, small-pox, measles, inflammatory fever: but he recommends it strongly in sanguineous apoplexy, phrenitis, and cerebritis; and we shall see that the moderns have not much more to say on the matter.

Mr Oliver Pemberton contributes to the same journal an article on an *Extensive Laceration of the Uterus and Vagina* between the fourth and fifth months of pregnancy, the particulars of which, although already noticed, are so interesting as to justify the reproduction of Mr Pemberton's article:

"On Tuesday, July 24th, under the Coroner's warrant, I examined the body of Sarah Sanders, aged thirty-nine, a married woman, residing at Hockley hill, Birmingham, who, I was informed, had died in consequence of a miscarriage on the previous Thursday, the 19th ult. Dr David Nelson, of this town, who had seen the woman immediately before her death, whilst she was attended by a druggist of the name of White, was present during the inspection.

"The body was that of a stout, well-formed woman, presenting no external marks of injury whatever. Decomposition had not advanced. Immediately adjacent to the uterine outlet was a large collection of clotted blood, that appeared to have passed out subsequent to the death.—Thorax: There was no effusion into the pleural sacs. The lungs were healthy, their posterior parts being congested from position. The heart and its covering were healthy; its cavities were completely emptied of blood; its valves and the great vessels were healthy.—Head: The coverings of the brain and the brain itself were pale in appearance; otherwise they were healthy.—Abdomen: The intestines were greatly distended by air. The liver, pancreas, spleen, and kidneys were perfectly healthy, but paler than natural. The pelvic viscera were in their ordinary position. The uterus presented the external appearances of having recently contained a fœtus at about the fifth month. On turning its back from the rectum, the peritoneal coat covering its posterior surface was seen to be split to the extent of an inch near the upper part; whilst the subperitoneal tissue about this point, and stretching onwards along the situation of the right broad ligament, was extensively filled by extravasated blood, but there was no blood in the cavity of the peritoneum. The urethra was natural. The bladder was natural and empty. The rectum also was natural. The vagina presented a laceration on the right side, near the upper part. This extended onwards through the adjacent lip of the os uteri, and through the uterine wall beyond. The edges of this laceration were irregular and torn, and were infiltrated with blood. It measured six inches in length, about equally divided between the uterus and vagina. The hand passed readily through this aperture amongst the tissues of the pelvis, the fingers lifting up the peritoneum behind the situation of the broad ligaments, in the direction of the extravasated blood previously described. The parts around, forming the walls of this cavity, were jagged and torn, but the peritoneum had not given way. The uterus was enlarged to correspond to between the fourth and fifth month of gestation. In all other respects, the uterus, vagina, and appendages were perfectly healthy. The placenta had not been separated from its attachment to the upper and posterior part of the fundus. Its structure was perfectly healthy. Its fœtal surface was ragged and torn, and there were no traces of the membranes or cord.

"The fœtus measured between eight and nine inches in length. It was well formed and well nourished for the age at which it had arrived, and presented no evidence of intra-uterine maceration. I deemed it to have reached between the fourth and fifth month of gestation.

"The previous history of this case, as detailed at the inquest, was as follows:—

"Sarah Sanders was pregnant with her fourth child, and believed herself to be gone about four months. On the 18th July, she was in her ordinary health; but in the course of the night she was seized with pains, which subsequently turned out to be those of premature labour. Some discharge of blood had taken place on the previous 17th and 16th. Her husband gave her gruel, and adopted the usual homely remedies; but as these did not tend to relieve her, a neighbour, a respectable woman in the habit of attending at births, was sent for between two and three o'clock in the morning of the 19th. At about five, White visited her, and gave her a mixture containing tincture of ergot, diluted sulphuric acid, tincture of opium, and infusion of roses. He then left. At a quarter past eleven she was delivered of the fœtus. Up to this time there had been no bleeding beyond a little draining. Between eleven and twelve, White again visited her. She was then losing blood, and the after-birth had not come away. At a quarter past one in the afternoon, this was stated to have been removed by White by the introduction of the hand, and was further described as being in a decomposed and diseased state. After this so-called removal of the after-birth the bleeding continued, she became very low, and died at a quarter to three o'clock, about an hour and a half subsequently.

"At the coroner's inquest, held on the 24th of July, I gave evidence to the effect—

"1st. That deceased had died in consequence of the combined effects of shock and hæmorrhage produced by the laceration in the uterus and vagina.

"2nd. That such an injury was inevitably mortal, death ordinarily taking place in a few hours.

"3rd. That the laceration occurred in consequence of attempts having been made to remove the after-birth by the introduction of the hand into the uterus.

"4th. That any such introduction of the hand into the uterus at that period of gestation (the fourth and fifth month) was uncalled-for and improper.

"5th. That, regarding the size of the fœtus, the absence of any enlargement of the head or abdomen, and the healthful condition of the uterus and vagina, it was impossible for such a laceration to have been produced during natural labour.

"The result of this evidence was, that the jury found a verdict of manslaughter against White; and on the 4th of the present month he underwent his trial at Warwick, before Mr. Justice Williams.

"The description which I have given of the parts as they appeared at the post-mortem examination was assented to in all particulars by Dr Bell Fletcher, one of the physicians to the General Hospital; and by Mr John Clay, one of the physician-accoucheurs to the Queen's Hospital in this town, who both of them carefully examined the structures removed from the pelvis.

"At the trial, despite the attempts made by counsel to attribute the death to the effects of diseased action and placental hæmorrhage, I maintained the opinions I had given before the corner as to the impropriety of the treatment, the nature of the injuries, and their influence on the death, being supported to the fullest extent by the testimony of the gentlemen to whom I have referred.

"In summing up, the judge, after presuming that the prisoner's mode of treatment caused death, narrowed the evidence to this question—'Is it a want of ordinary skill to be ignorant of that which may be done at one stage of pregnancy and not at another?' It was a fact also to be taken into consideration, in judging of the man's skill, that the patient was in humble circumstances. Was it a want of ordinary skill and ordinary care? If in doing his best he did that which, in the knowledge of the medical witnesses, was most certainly fatal, then did he bring such an inefficiency of skill and care to his task as to render himself amenable to the law of the country?

"The jury, after a short consultation, acquitted the prisoner."

M. Claude Bernard's Lectures on *Experimental Pathology* are continued in the 'Medical Times and Gazette.' *The Analogy between Morbid Causes and Poisons* is the special subject of this article. The following remarks are interesting:

"Morbid anatomy must not, therefore, be considered as a key to all the phenomena of disease: viewed by itself, it is utterly incapable of pointing out the hidden sources from which they spring; and mere anatomical investigations, however minute, are altogether insufficient in this respect. In making experiments upon the abdominal nerves, I have frequently seen animals die before any symptoms of inflammation had made their appearance; and Chossat's interesting researches on the effects of starvation equally afford instances of sudden death under similar circumstances. Thus, in animals entirely deprived of food, a given period usually elapses before life is altogether extinct; but, when the process is already far advanced, the slightest shock is sufficient to destroy life at once. A pigeon, which has been kept fasting for a considerable length of time, falls down, and instantaneously dies, when its claws are nipped; while, if not interfered with, the animal's life is usually prolonged for several days. It would, of course, be quite necessary to state, that in making the autopsy, no alterations besides those which ordinarily result from inanition are met with. In what manner, therefore, is death to be accounted for in such cases? Chossat attributes it to syncope; an opinion which our own experiments tend to corroborate. In fact, the heart's motion (as we have elsewhere stated) is momentarily arrested when a sensitive nerve is painfully excited; it would, therefore, be quite possible that in animals reduced to a state of great debility, a slight sensation of pain should immediately produce death. There also exist, in such cases, other conditions, which the mere anatomist is unable to appreciate. The temperature of the medium in which animals are kept during the process of starvation, has a considerable influence upon the duration of life: for cold accelerates, and warmth opposes, the destructive process; and, in experiments in which circulation has been arrested in some of the larger vessels, we also find this to be the case. When the vena porta, for instance, has been tied, the animal is soon deprived of its natural heat, and rapidly dies, if the temperature of the body is not maintained in a proper state by artificial means; but when this precaution has been taken, the results of the operation seldom prove fatal.

"It would not be difficult to accumulate a still larger amount of evidence upon this point; but you have no doubt been fully convinced, by the facts to which we have just drawn your attention, that nothing beyond the mere mechanical causes of death is explained by morbid anatomy, and that other and more comprehensive modes of investigation are indispensable to those who wish to acquire a deeper insight into the secrets of living nature. To fill up this void as far as possible, is the chief purpose of our present researches; but in pursuing this object we must never lose sight of the example left us by those illustrious observers to whom the biological sciences are indebted for all the progress they have accomplished in moderations. The concatenation of natural phenomena, their mode of precession, and the laws according to which they are produced, must alone become the subject of our studies; as to the intimate nature of things, it lies entirely beyond the reach of human knowledge. It would not, for instance, be sufficient to state that certain poisons act upon the nerves, others upon the muscles or the blood; but when the peculiar mode of action of such bodies upon our tissues and the mechanism through which life is extinguished have been thoroughly ascertained in each case, we can go no further; to explain the mysterious properties which enable a given poison to disorganise a given tissue, is not within the power of science. You remember, no doubt, the effects produced by oxyde of carbon upon the blood-globules—you are aware that a chemical combination takes place between these two bodies, which opposes the absorption of oxygen, and brings on a peculiar kind of asphyxia; the mechanical process of respiration still continues, but is no longer attended with the revivification of the blood in the lungs. Here, then, we have a satisfactory explanation of the deleterious influence exerted by this substance; but if we were asked *why* the combination takes place, we should of course be unable to answer the question. The affinity of oxyde of carbon for the blood-cells is evidently superior to that of oxygen, but the primitive reason of this difference lies beyond the limits of our scientific knowledge.

"The physiologist must therefore be contented with tracing back the effects produced by disease to some primitive cause, the discovery of which puts an end to his inquiries; and the influence exerted by toxic agents upon the organs of the living body will in this respect be found to exhibit a striking analogy with that of morbid causes. In what manner is the agency of poisons to be conceived? Ought their effects to be viewed in the light of chemical combinations, which supersede the physiological changes that support life? Such is in fact the explanation we have adopted, as regards the action exerted by oxyde of carbon upon the blood-globules; but would it be proper to extend these views to all the different poisons with which we are at present acquainted? Are we to suppose that woorara is chemically combined with the substance itself of the motor nerves, so as to impede the progress of the nervous fluid? A similar hypothesis would evidently not be in accordance with facts: we find that when life has been protracted by artificial means, the deleterious agent is gradually expelled from the economy: now, if a permanent impression had been produced upon the nerves, we should not find this to be the case.

"It therefore appears that toxic agents exert different modes of action upon the fundamental conditions of life: in some instances they seem to be chemically combined with the histological elements of the disorganized tissues: such, according to Liebig, is the case with respect to metallic salts. Other poisons, on the contrary, circulate freely with the blood, and destroy for the time being its vital properties. Now, the blood, as we have already stated, is the common medium in which all the tissues exist: if therefore a deep change occurs in its physiological properties, both muscles, glands, nerves, and other organs, are liable to experience a total derangement in their usual functions. The well-known experiments of Bichat upon the injection of venous blood into the arteries afford a striking example of this; and it can scarcely be questioned, that such is the mode of action exerted by woorara, strychnia, and all the other substances which are speedily eliminated from the body, when death has not been almost immediately the result of their presence.

"It would therefore appear, that poisons might, in this respect, be divided into two principal classes: some of them give rise to stable and definite chemical compounds, are retained within the economy, and may be discovered by the process of analysis after death; others are speedily expelled from the body, and leave no visible marks of their passage. In the first case, permanent and incurable effects are produced; in the second, a transitory action is alone exerted, and when the patient recovers, the noxious principle has entirely disappeared. In short, gentlemen, we find, in all respects, a perfect resemblance between the effects of poison and those of ordinary diseases; and in our next Lecture we shall endeavour to complete the parallel between them."

Mr Le Gros Clark contributes a Clinical Lecture on various cases. We extract the following reports of cases:

"The details of this case are too interesting and instructive to pass over summarily, and I will therefore read to you an abstract from the report of my dresser, Mr Ward:

"G. S., aged 30, a sober and healthy man, was admitted into the hospital on June 11. While at work he was struck by the revolving arm of a crane on the left temple, and thrown violently to the ground. He was quite insensible when brought in; pupils inactive, pulse quick and feeble, surface generally cold and clammy. He was bleeding profusely from the left ear,—I say profusely, for I have rarely seen blood escape so freely from the auditory canal: it was of a bright florid colour. He had three scalp wounds,—one on the forehead, where the arm of the crane struck him, and two on the back of the head, occasioned, apparently, by the fall. There was also a punctured wound over the left scapula, the spine of which was broken across, and a considerable quantity of blood had been lost from this wound. Ice, in a bladder, was applied to his shaved head, and his water was drawn off.

"The bleeding from the ear did not cease until eight hours after the patient's admission. During the succeeding two days he continued in nearly the same condition, swallowing a little sop and milk when he was fed. His water was either drawn off, or passed unconsciously; the action of the bowels was also involuntary.

"About the fourth day he could be roused so as to answer questions, but immediately relapsed into a state of stupor. Bleeding from the ear recurred, and lasted for some hours, about this time. On the fifth day there was commencing paralysis of the left facial nerve, evinced by the usual appearance of the mouth and forehead, and by inability to close the eye. It was evident that this loss of power was limited to the seventh nerve, as the tongue could be thrust out without perceptible deviation to either side; and there was no apparent interference with the movements of the jaw, or with deglutition. My dresser thought the whole of the left side of the body was affected in a degree; but I cannot say I detected any satisfactory evidence of this. He continued in this state for some time, the bowels being regulated, a light diet supplied, and the head kept cool. The paralytic condition of the facial muscles increased, until it became very decided on the tenth day; and then swelling and redness appeared on the left ear, which extended gradually over the upper part of the face, like erratic erythema. On the eleventh or twelfth day he began to ask when he wanted to make water or evacuate the bowels, and to answer questions rationally. His diet was gradually and cautiously improved. There were occasional paroxysms of flushed face and quickened pulse, requiring the exhibition of an aperient.

"There is but little further to report beyond his gradual improvement up to the present time, which is nearly six weeks since the occurrence of the accident. He is now up, and walking about. The paralytic condition of the face continues, though in diminished intensity. He is of course very feeble, and requires careful watching; but he is recovering strength.

"The diagnosis which I originally formed in this case, from the character, intensity, and persistence of the symptoms, was, that the base of the skull was fractured; and I see no reason to withdraw this opinion, although the issue has belied my prognosis.

"Free bleeding from the ear is a suspicious, but by no means conclusive evidence of injury to to the petrous bone; indeed, it not unfrequently occurs, as in the case I narrated to you in my last lecture, where speedy recovery from concussion may be accepted as proof that no bony lesion existed. In the present case, however, the state of the patient for many days was such as to confirm the suspicion of fracture, and some severer mischief than simple concussion of the brain. The subsequent paralysis of the facial nerve would seem to admit of an explanation on this supposition; for it may be readily conceived that this nerve, while in the Fallopian canal, might have escaped the immediate effects of a fracture of the petrous bone, but have been subsequently pressed upon by the deposition of new material during the early stage of reparation,—at least, such is the interpretation I am disposed to put upon the symptoms. Doubtless the patient will still have a tedious convalescence; and I shall be very anxious to keep him under my eye for some time to come, as we have already had proof that he cannot bear any mental agitation, or physical excitement, without suffering. He is a quiet, well-conducted and sober man, and owes much to this temperament. I may remark that I watched for serous exudation from the auditory canal, but could not discover that there was any appreciable discharge of this sort. His fractured scapula, which was of course attended to by careful bandaging and suitable dressings, has quite united, and the limb is already serviceable.

"I will now direct your attention to a case of not frequent occurrence, viz., suppuration of the globe of the eye:—

"F. P., aged thirty-five, was admitted into the Hospital on July 10. He states that he lost his sight in the right eye when young, but that it presented the same appearance as the other, with the exception of opacity of the cornea. Eight months since this eye was acutely inflamed.

"This attack was relieved; but a second attack, still more acute, came on four days ago, attended by violent pain in the head shooting up to the crown, distressing sense of distension of the globe, with swelling and inflammation. On admission, these symptoms continued in an aggravated degree. When approaching the patient, my first impression was that I had to deal with a case of acute purulent ophthalmia. There were the swollen red upper lip overhanging the lower, the purulent discharge clinging about both, and the projecting fold of chemosed conjunctiva, characteristic of this fatal complaint. But, on more careful inspection, I found other indications of deeper seated mischief. The prominence and projection of the upper lid was due principally to a corresponding projection of the globe itself, the tunics of which were evidently excessively distended. The pain was aggravated by pressure. The cornea was, as I remarked, opaque before the attack; the conjunctiva presented a chemosed fold around it. I then learned that this affection of the lids succeeded the acute, deep-seated pain and suffering in the head. The constitutional disturbance was less than I should have expected, although considerable. Under these circumstances I came to the conclusion that I had to treat a case of deep-seated inflammation of the globe, terminating in suppuration; and the indication was clearly to give relief by puncture. I accordingly introduced a bistoury through the cornea. At first the aqueous humour escaped in a limpid state, and on carrying the knife deeper, a considerable quantity, probably nearly a drachm, of pus escaped, mixed with vitreous humour. The patient expressed himself as feeling immediate relief. Fomentation and poultice were ordered, a supporting diet permitted, and four grains of extract of henbane with a quarter of a grain of morphia at night.

"On the following day the discharge was evidently confined, so that I thought it expedient to extend the opening in a crucial direction through the cornea, which was attended by a fresh discharge of pus and humour; and I also made some radiating incisions through the chemosed conjunctiva, to relieve the distension of the vessels. Since this visit nothing further has been done, except to regulate the bowels, improve the diet, and continue the local palliative applications. He is now using a mild astringent wash, and the eye is gradually resuming its normal dimensions, and the suffering has almost entirely ceased. This case speaks for itself, and scarcely needs comment; though I may remind you, that a superficial examination of the eye might, and probably would, have led to a wrong diagnosis, and neglect of suitable treatment. The sight was already lost; yet I apprehend if this had not been the case, the treatment must have been the same; for the vitality of the cornea was already impaired, and would probably soon have been lost. I can trace no constitutional, accidental, or specific cause for this attack; the rapidity of its course proves its formidable acuteness, and the issue is a simple and natural consequence of the treatment, as that of an ordinary abscess, which involves sensitive, and is surrounded by dense textures.

"I operated last week on a boy, aged 15, for stone. The case presents nothing unusual, except that he had been previously, as much as six years since, operated upon in his native county; but, as the father of the lad writes, 'the attempt was not successful, his bladder not being entered; and consequently (as he rather quaintly adds), no stone was taken out.' Previous to the removal of the calculus, the sufferings of the boy were very great, unusually so; but, since the operation, he has not had a bad symptom. I have often remarked, that patients who suffer most before operation give least cause for anxiety afterwards; I suppose because the relief is relatively greater. The stone weighs about an ounce, and is rough and modulated on the surface like the oxalate of lime deposit, but it is light in colour: it has not yet been analysed. . . .

"Lastly, I may tell you that the patient whose carotid artery I tied six or seven months ago, has recently presented himself at the Hospital, looking and expressing himself as feeling perfectly well and free from any inconvenience. In this, as in another similar case, reported in vol. xxx. of the 'Medico-Chirurgical Transactions,' I tied the trunk of the common carotid for a penetrating wound of the neck behind the angle of the jaw, attended by profuse arterial hæmorrhage. I remember the former case was criticised by an authority of much weight, the late Mr Guthrie; but I am convinced the course I pursued was the right one, as I could not be satisfied in either in-

stance that the internal carotid was not implicated in the mischief; and, moreover, I think the external carotid offers a very unsatisfactory prospect to the operator, dividing as it does so immediately into numerous and large offshoots to the surrounding structures."

Mr W. Michell Clarke reports a case of *Epithelial Cancer*. The woman suffered from hæmorrhage from the bladder, subsequently dropsy in the right leg caused by the blocking-up of the right femoral vein. Then an abundance of cells, many caudate, appeared in the urine. We give the *post-mortem* appearances of the case:

"On the 22nd an examination of the body was made. It remained very yellow. It was thin, but not much emaciated. The right thigh and leg were very much swollen, and the pitted deeply on pressure. The brain was in a healthy condition. The right pleura was inflamed; the inflammation was recent, and evidenced by a small quantity of fluid and a patch of yellowish lymph. The lungs and the heart presented no mark of disease, except that the mitral valve was slightly thickened.

"The liver and spleen were healthy. The right kidney, as it appeared to the naked eye, was in a state of fatty degeneration. The left kidney was a good deal larger than natural. Its surface was studded with rounded nodules, of various sizes, the largest, however, not larger than a pea. The capsule was elevated by these nodules, and passed over them. When a section of this kidney was made, it was found that its lower third was occupied by a morbid growth, which was deposited in the shape of three or four masses of rounded outline. These masses were quite soft, and readily yielded to pressure a grumous material. The colour of the cut section was pinkish brown. The ureters were of the usual size, and did not appear unhealthy, but they were not cut open.

"Upon examining microscopically one of the nodules above mentioned, I found that it was made up almost wholly of cells. These for the most part had the size of the cells which line the tubuli uriniferi, but there was also intermingled with these a large number of cells having the characters of squamous epithelium. These were of large size, and contained a large and well-formed nucleus, and sometimes the nucleus showed a well-marked nucleolus. Some of these cells had the appearance of containing two or even three nuclei, but the outline of these apparent nuclei was dim and confused. There were also found, in the fragment of the nodule, some portions of tubuli uriniferi.

"In the portion of the deposit from the lower part of the kidney, which I examined, there were a less number of cells having the size and appearance of renal epithelium cells. This was almost entirely made up of large cells, having the appearance of tesselated epithelium, with large single nuclei. Most of these cells presented a greater or less number of minute fat-globules. The whole field was obscured by greasy matter, and one or two fragments of tubuli were seen, which were studded with fat-globules, and their epithelium was very obscure.

"The bladder was very much thickened, the thickening being due, as was found when the organ was cut open, to the mucous membrane. Over the posterior part of this membrane there was spread out a thick slate-coloured deposit, somewhat granulated on the surface, and quite firm to the touch. Upon section a surface of the same colour, smooth and homogeneous, was presented. Upon microscopic examination this deposit was found to be composed of very minute molecules, with numbers of minute fibrils; also some apparently ill-formed pus-cells; also large numbers of large crystals of triple phosphate; and, lastly, large numbers of epithelium-cells, probably bladder epithelium.

"Around the orifice of the left ureter there was a fringe of delicate vegetation in which numerous vessels were very evident. These vegetations were very soft, and contained a matter almost diffluent, and of the colour of cream. They were too soft to afford a satisfactory section. A thin layer of the whitish material, which was contained in these growths, under the microscope, was seen to be made up of epithelium, of tesselated character, with large nuclei. The cells were distinctly arranged in dense, concentric, rounded, or oval balls (epithelial globes).

"The fringe above described afforded the most characteristic features of epithelial growth; but other parts of the mucous membrane were studded with small tubercles about the size of peas (between which the membrane presented a natural appearance), which were made up of delicate fibrous tissue, and epithelium cells of squamous character, arranged apparently as epithelial globes; but I could not not get any out distinctly.

"The right ureter opened through a firm and thick mass of whitish colour, which presented upon section the characters of medullary disease. Some more deposit, similar to this, was spread out towards the entrance of the urethra. When submitted to minute examination it did not turn out to be soft cancer, but was found to be made up of delicate fibres densely interwoven, and also of epithelial cells between the meshes. I could make out no epithelial globes in this.

"Perhaps the most interesting feature in the above history is the deposit of epithelioma in the kidneys, affording, as it does, another case in evidence of the malignant character of this disease. The rarity of secondary deposit in internal organs might appear to tell against the evidence which is derived from the destruction which this disease effects by continuity; but such cases as the present afford this additional character of malignancy—that this disease, which is like the more acute cancers in its other features, is also like them in its capability of reproducing itself in internal organs.

"There were other morbid changes in this woman's body of considerable interest. On the anterior surface of the uterus there was a small fibrous tumour; on the posterior, there was another; in its cavity there was a small and soft polypus attached just within the cervix by a narrow pedicle, and standing up through the cavity until it reached the fundus. In the ovarian veins there were several phlebolites.

"The right femoral vein was densely plugged with coagulated blood, which was partly adherent to its inner coat, and softening in the centre. One of the clots contained a diffluent material, closely resembling pus in outward characters. There were large clots also in the external iliac vein of the right side.

"In the treatment there was only one point of interest. Creosote was effectual every time in stanching a hæmorrhage over which the more commonly used styptics exercised no control. This I consider well worth bearing in mind."

Mr Gaffney reports in the same journal a case of *Comminuted Fracture of Skull with loss of Brain Substance*, treated successfully. After the cure, the only appreciable alteration was a slight restlessness. Mr Gaffney attributes much of the success to the plentiful supply of ice and the constant application of wetted lint.

The 'Dublin Medical Press' contains the following article, by Mr Donovan, on the medical efficacy of the *Liquor of Hydriodate of Arsenic and Mercury*:

"In the 'Medical Press' of May 23rd, I find it stated that Professor Hebra, finding no benefit to be derived from the usual remedies in psoriasis, confines himself to the use of arsenic. 'He employs Fowler's, Pearson's, and Donovan's solutions.' 'Donovan's solution he finds easiest borne, but the least efficacious.' This statement is diametrically opposed to those of Marsh, Graves, Croker, Colles, Cusack, Williams, O'Ferrall, Carmichael, Kirby, Irvine, W. T. Hamilton, J. C. Ferguson, Bigger, O'Reilly, Osbrey, Hickson, White, Jones, and many whose cases have not been published. By these practitioners the liquor of hydriodate of arsenic and mercury, or, as it is for the sake of brevity called, 'Donovan's solution,' has been found to succeed when every other medicine had failed. It was also, in several cases, ascertained that arsenic, mercury, and iodine separately exhibited were unsuccessful, but the compound of the three succeeded. The curative powers of the compound were not confined to psoriasis, but were equally beneficial in some other skin diseases.

"Did Professor Hebra satisfy himself with regard to the composition of the solution he employed; was it prepared with the somewhat laborious care which is essential to its success; was the exact ratio of pure ingredients made use of; was the iodine resublimed and dry? Without attention to all these particulars, diminution of medical efficacy would not be surprising.

"I ask these questions in consequence of some circumstances which have long since come to my knowledge; but which, however I might regret them, I did not hitherto feel called upon publicly to notice. I published my process many years since: it was unavoidably tedious and troublesome: many persons were induced to prepare the liquor, but, owing to causes which I have elsewhere explained, they in several instances obtained a worthless result. One cause was the mistake of the meaning of the word 'arsenic,' directed in my published process. I of course intended the metal arsenic; the article employed in the cases alluded to was the white arsenic of commerce—the oxide of arsenic—which could not enter into combination with the other ingredients. Accordingly, the so-called liquor of hydriodate of arsenic and mercury, which was unluckily employed in the practice of some physicians, contained no arsenic, and totally failed. Such specimens were frequently brought to me by disappointed prescribers.

"But the mistake about the nature of arsenic to be used in preparing this medicine was not the only cause of its inefficiency; frequently, the full quantity of the three elements, although present, had not been brought into combination, and therefore they did not entirely dissolve; the result was a solution more or less feeble, and the consequent failure of doses calculated on supposition of full strength. The same ill effects, to a corresponding extent, would be produced by the impurity of even one of the elementary ingredients.

"But even were the three elementary bodies pure, if due care were not taken in effecting their combination, a variable quantity would combine and dissolve, and even a considerable ratio of them might remain insoluble in the liquid, instead of forming a perfect and transparent solution.

"When all these circumstances are taken into consideration, we shall be at no loss to understand the cause of the less efficiency of this medicine in the practice of some physicians. Fortunately, its character is sufficiently established by its extensive employment, and by the published statements of practitioners whose eminence is sufficient security for their competence to form a sound judgment."

ACTION OF DENSE MEDIA UPON BLOOD CORPUSCLES.

M. Serge Bothine finds that hematosine does not always take part in the exosmotic current which is produced by the action of concentrated media upon the blood corpuscles. Although the latter contract more or less under the influence of the exosmotic action, they do not become less coloured than before, and even acquire a more vivid tint. The globules eventually collect at the bottom of the vessel, and leave the fluid above colourless; after some time they regain their original form without the liquid undergoing any change.

To observe this phenomenon, the red globules of mammalia must be acted upon by concentrated solutions of sugar or sulphate of magnesium. If instead of these two substances we employ concentrated solutions of chloride or sulphate of sodium, the globules contract as they always do under the influence of the exosmotic current, but lose at the same time their colour, and leave the liquid of a brilliant red. Experiments were also made upon bile. The bile of an ox or sheep confined in a little bladder, or tube closed with the membrane of an egg, was placed in a concentrated solution of sugar or sulphate of magnesium. Under these circumstances the colouring matter was perfectly retained. In the solutions were found acids of the bile, but no trace of the colouring matter. If the solutions were replaced by those of chloride or sulphate of sodium, they acquired a strong colour in the space of a few moments, and contained a large quantity of the acids of bile.

These experiments may throw some light on the curious fact of the distribution of the principles of the bile in the liver, viz., why the bile formed in the cells of the liver is carried into the excretic canals, without ever being diffused in the blood of the vessels, except in pathological cases. The sugar of the blood of the hepatic veins plays probably a certain part in this phenomenon. Some cases of jaundice, in which it is impossible to discover a mechanical cause for the retention or absorption of bile, may perhaps, after these experiments, find their explanation in some change in the conditions of diffusion.—'London Medical Review.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B—The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

TERMS FOR ADVERTISEMENTS.

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 22, 1860.

THE OUT-PATIENTS' DEPARTMENT.

If the Special Hospitals be in principle unsound, the General Hospitals are not without their abuses. The harm done by the Special Hospitals is problematical, that done by the General Hospitals is too positive to be questioned. It seems odd to declare it, yet it is no less true, that the very largeness of the resources of some of the General Hospitals is the immediate cause of their chief evils. The funds having outgrown the necessities of the Hospitals as at present organised, a need has been created for the employment of the income in a collateral channel; and hence the Out-Patients' Department has been allowed to undergo a disproportionate development. The vast numbers said to be attended at some of these Institutions are the boast of the Governors, and are set forth as a proof of the immense benefits conferred on the community. The utter delusiveness of this fallacy could be easily proved on a close examination of the mode in which the attendance is given, and of the results attained. We have frequently exhibited the anomalies of this system: it has been an invidious duty, but its necessity and advantage to the public and the Profession are now proved by the fact that the Medical Officers themselves are coming forward to advocate the views and to wield the identical arguments which the MEDICAL CIRCULAR for a long time single-handed battled to maintain.

In consequence of the larger Endowed Hospitals having set up their Out-Patients' Department as the criterion of their usefulness, the other Hospitals which are maintained by voluntary subscriptions have been compelled to follow their example; hence pecuniary embarrassment has become among them a chronic malady, and in more than one instance has threatened the Institution with ruin. This is, however, the least of the bad results of this artificial system.

Perhaps the worst evil is the cursory and inadequate attendance given to the poor persons who attend these Charities in the hope of obtaining the best advice. Here, again, we are trespassing upon forbidden ground. It seems to be almost an act of professional treason to call in question the quality of the professional aid bestowed at these Institutions; yet there must be hundreds of Medical men in this Metropolis who can testify to the oversights and negligence arising out of the rapid and perfunctory way in which the duty is generally discharged in the Out-Patients' Department. Facts are "plentiful as blackberries," but we need not recapitulate even a dozen: the point is, how is the system to be rectified?

In the first place, (recognising, for the sake of argument, the existing extension of the Out-Patients' Department,) it becomes a duty on the part of the Governors to be consistent, and to secure for the poor that amount of competent professional assistance which they profess to give. The liberality of the Medical Staffs has not grown with the increase of the funds of the Institutions; hence the development of the system of Hospital relief has not been accompanied by a proportionate increase in the number of Medical and Surgical Officers. The jealousy of the Officers themselves has prevented this augmentation. The honour and profit are the greater as they are the more exclusive; and those who are already in office have no wish to see the advantages participated in by ambitious men outside the circle of privilege. On the supposition, then, that the Out-Patients' Department is to be maintained at its present magnitude, it is but just towards the poor, and equitable towards the Profession, that the door of office should be thrown more widely open, and a much larger number of Physicians and Surgeons be appointed to discharge the routine duties of these Charities. Retain the Out-Patients' Department, and this must be done. Let the public but once fairly understand how the work is gone through at these Hospitals, and they will not tolerate the continuance of the system for the exclusive benefit of a few individuals. An Assistant-Physician at St. George's Hospital has helped to expose the unsoundness of the system, and a few more voices, speaking with equal authority, will inevitably accomplish the desired change. These gentleman can reform the system if they please: we ask them for their help; for it is disconraging to be suffered to fight a hard battle alone.

Another and the fundamental evil of the gigantic growth of the Out-Patients' Department consists in the admission to eleemosynary advantages of thousands of persons who are able to pay a private Practitioner for his advice. Indeed, unless such a gross and shameful abuse of Charity funds were encouraged, the patients could not be found. Dr Guy has proved this very clearly by an analysis of the persons attending the Out-Patients' Department of King's College Hospital. He has shown that a very considerable number of those patients must consist of well-paid mechanics and respectable tradesmen, and their families. Is this right? Most assuredly not. Charity funds were never subscribed to relieve those persons of the duty of providence, and to acquit them of the moral obligation of honestly paying for benefits received.

We regret to say it, but we have been assured of the fact, that the attendance of this class of persons is encouraged by the Medical Officers of some of our Metropolitan Charities. One gentleman has been named to us who makes 200*l.* a year by visiting patients at their homes after he has acquired their confidence as out-patients of his Hospital. He has organised his opportunities into a system which he finds so profitable, that the higher office in the Hospital fails to have any temptations to his ambition. Other gentlemen are noted in our Memoranda as remarkable for turning to pecuniary account this abuse of Charity. But, in fact, the evil is a frequent topic of indignant remark in certain Metropolitan circles: it is, moreover, a growing one. The sentiment of justice itself is made a cloak for the acquisition of a private practice through the medium of the Out-Patients' Department.

We conjure our brethren in office and out of office to ponder anxiously over these matters. Rigorous inquiry and reform are demanded, in justice to all the parties concerned. The Out-Patients' Department has grown up imperceptibly to its present magnitude without due regard to the strength of the Hospital Staffs, the just claims of the sick, or the interests of the Profession. Vigorous remedies must be applied; we have pointed out the nature and extent of the morbid growth, the duty of excising it rests with executive hands.

SUMMARY OF THE WEEK.

SPECIALISM.

The attack upon Special Hospitals is gradually losing its vigour, and our contemporaries, originally so vehement in their opposition, are beginning to think that, after all, it is a case for inquiry. In our opinion, the inquiry should have been made before sentence was pronounced. We have published in another place a full report, from the 'British Medical Journal,' of a discussion that took place upon this subject at the Annual Meeting of the British Medical Association, and we confidently appeal to the judgment of our readers, whether the preponderance of argument was not on the side of those who justified a special cultivation of Medical and Surgical Science, such as Special Hospitals afford the only means of prosecuting under the existing arrangements for Charitable relief. Little can be added to the vigorous and pointed good sense of Drs Thudichum,

Routh, and Richardson. The truth is, nearly all the recent improvements in Medical and Surgical Practice have been either introduced or perfected by Specialists. Did our General Hospitals introduce Orthopœdic Surgery, or the operation for vesico-vaginal fissure, or the ophthalmoscope, or inhalation for anæsthesia? Some of these improvements are now practised in those Institutions, but not one of them originated there. Again, is it not notorious that patients afflicted with cancer, phthisis pulmonalis, exanthematous fevers, chronic affections of the nervous system, and, in short, chronic diseases generally, are systematically refused by the General Hospitals? Why, then, should not Special Hospitals be established for the accommodation and cure of persons so afflicted? Are the patients who suffer most hopelessly to be least provided with the means of relief? When we wrote our article on "Special Hospitals," we were aware that Sir Benjamin Brodie was then under the treatment of a Surgeon of one of our Ophthalmic Hospitals; but, from considerations of delicacy, we refrained from adverting to the fact. Sir Benjamin's case having been made public, there is no longer any necessity to attempt to conceal his infirmity. It seems to us very clear that Sir Benjamin's exception in favour of Ophthalmic Hospitals was influenced by the consideration of his individual case, and this circumstance consequently destroys his argument. Sir Benjamin, anxious to have the best treatment, did as every other man who had the opportunity would: he consulted the Practitioner who was supposed to have the largest experience in the Specialty;—an act which is a tacit confession of the importance of the special cultivation of certain branches of Surgical Practice. We are not the advocates of an infinitesimal subdivision of Medical Practice, and should deplore it: on the other hand, we think that many of our Special Hospitals are a blessing to the community, and we do not wish to see their efficiency impaired. It must not be overlooked that the chief leaders of this onslaught upon Special Hospitals are the Members of the Council of the College of Surgeons, who have themselves done all in their power to legitimize Specialism by granting Special Diplomas. The motive for such contradictory conduct appears obvious: they desire to obtain more fees in the one case, and fear to lose them in the other. The argument that the Medical Schools will be deprived of the means of educating Students by the withdrawal of several forms of disease if Special Hospitals continue to be erected, is too absurd for serious notice, when we remember the vast population of London and its rapid increase. The great advantage of a Medical Education in Paris, is the extent and number of its Special Hospitals.

MEDICAL REPRESENTATION IN PARLIAMENT.

Ardent upon the subject of Medical Representation in Parliament, Dr. Mackesy of Waterford has induced the British Medical Association to come to a resolution recognising the importance of the principle. We confess to the desirability of our attaining this end; but, in the present state of the Profession, we do not conceive that we should be much the better for it, unless—and this is the point—the Representatives were elected by the entire body of the Profession. We would strenuously oppose any attempt to limit the suffrage either to the governing or the electoral bodies of the Corporations; and we may be quite sure that the Corporations would not like to see it in the hands of the general body of the Profession. Let Dr Mackesy define the mode in which he wishes to see this representation of the Profession carried out, and we shall know better how to deal with his proposition. In the abstract there is no public principle of greater importance.

THE SENTENCE ON YOUNGMAN.

In the course of the trial of Youngman, who was charged with the murder of his mother, brothers, and sweetheart for the purpose of securing an insurance of 100*l.* upon the life of the latter, Dr Duncan, in whose service the prisoner had lived as footman, was asked certain questions relative to his sanity; and he deposed that it was possible that a man might have an irresistible homicidal propensity, notwithstanding that he might have a perfectly clear knowledge of right and wrong as regarded the crime he contemplated, and might be in all other respects sane. We have nothing to say in opposition to this opinion; alienists put their faith in it, and facts confirm it; but we do most sincerely hope that no Medical man will ever voluntarily put forth such an opinion in the witness-box with the hope of screening a malefactor from the sentence that is the reward of his crime. As there is no doctrine more critical, so there is none more dangerous. How is it possible to decide upon the guilt of a man in any atrocious case of murder, if this theory be admitted into our Courts of Law? Who shall define the limit between a settled spirit of revenge or malignant passion, and this impulse of homicidal propensity? The heart of man is "desperately wicked;" but we firmly believe that even its "homicidal propensities" may be kept in check by the conviction on the part of bad men, and even mad men, that the law will not grant an immunity to their crime upon such a doubtful plea. On the contrary, once allow it, and there is scarcely any villain who will not have the wit to turn it to account; and the effect will be an indirect encouragement of crime. We must set our faces against Doctors and Counsel hatching such a plea to screen great offenders; otherwise the Courts of the Old Bailey will soon be filled with monsters of wickedness and puling philanthropists. We are glad to exempt Dr Duncan from any censure on this point; his explanation in the 'Times' showing that he merely gave an opinion as a scientific man in answer to a question put to him by Counsel. The danger, however, in these cases is, that a few isolated facts may be advanced to support a theory with the hope of excusing the enormity of particular crimes.

PROFESSOR BENNETT'S ADDRESS.

In his capacity of Professor of Medicine in the Edinburgh University, Dr Bennett has pronounced a good address on the occasion of the capping of the Students who have obtained their degrees. A vein of good sense and temperance runs through this oration, although some sharp things are said about the conduct of the Edinburgh College of Physicians; but we trust the College will not be offended. What they did was done in a liberal spirit;—at any rate, the matter is over, and the Government have approved it by refusing to allow a change in the Medical Act, proposed to be made in it to the disadvantage of the Licentiates. "Let bygones be bygones" is the wisest policy.

CRIMINAL LUNATICS.

A very salutary change of the law has recently been made with respect to Criminal Lunatics confined in Bethlehem. Hitherto a prisoner remitted from the penalty of the gallows on the plea of lunacy has been confined for life in Bethlehem Hospital: for the future, however, this custom will be altered, and those persons certified to be sane will be dealt with as such, whilst the insane will be removed to other Institutions and placed under the provisions of the Lunacy Acts. The Government are about to build a new Asylum for Criminal Lunatics.

THE OPERATION ON SIR BENJAMIN BRODIE.

Our contemporary, the 'Medical Times and Gazette,' has chronicled some of the particulars of an operation recently performed on Sir Benjamin Brodie for the cure, as was believed, of glaucoma, *apropos* of a paragraph in the 'Times.' We reproduce our contemporary's remarks:

"This public allusion to a subject in which the Profession naturally take a deep interest renders a longer silence on our part impossible, and it becomes our duty to let our readers know that the operation of iridectomy was performed on both Sir Benjamin's eyes on July 12. His sight had been failing since Christmas last, but was not painfully defective until the completion of his seventy-eighth year in June. About that time vision became rapidly more and more impaired, especially in the left eye. Up to this time the disease had been regarded as senile cataract, more advanced in the left eye than in the right; but after the return of Sir Benjamin from the meeting of the British Association at Oxford, the defective vision was ascribed to glaucoma. Iridectomy was performed under chloroform. We deeply regret to say that the result is not so satisfactory as the paragraph in the 'Times' might lead the Profession to hope. The left eye we believe to be much in the same state as before the operation—if any-

thing slightly improved; but in the right, or better eye, vision is quite lost. The great ground of hope in this case is that as there is now a cataract very evident in the right eye, this is the cause of the impaired vision; that the eye is not glaucomatous, and that hereafter vision may be restored by extracting the cataract. We have not alluded to this subject before, as it is to some extent a private matter; but the whole Profession have so filial an interest in all that relates to the respected President of the Royal Society and of the Medical Council, that all have a right to know as much as is freely talked about in the Medical coteries of the metropolis—especially at the present time when a comparatively new operation like iridectomy is on its trial."

Our readers will hear with much regret of the unfortunate issue of this operation.

LETTER FROM THE REGISTRAR.

To the Editor of the Medical Circular.

SIR,—A good deal of uncertainty appears to prevail as to the Regulations proposed by the Medical Council respecting the General Education and Examination of Students.

This uncertainty has probably been increased by the circumstance that in the Report of the Committee on Education, as it appears in the 24th number of the Minutes of the General Council, the present year, 1860, has, through a misunderstanding, been fixed for the compulsory Registration of Students, instead of, as it should be, the ensuing year, 1861.

I think, therefore, that it would be useful and acceptable to many of your readers, if the following Resolutions of the Medical Council, which bear upon the subject in question, were placed before them in the following order:

6. That after October 1st, 1861, all Medical Students be required to be Registered.

8. That no Student beginning Professional Study after September, 1861, be registered, who has not passed an Arts Examination, in conformity with Resolutions 2 or 4, viz.:

2. That, as far as may be practicable, Testimonials of proficiency granted by the National Educational Bodies, according to the following list, be accepted, with such additions as the Medical Council may from time to time think proper to make.

A Degree in Arts of any University of the United Kingdom, or of the Colonies, or of such other Universities as may be specially recognised from time to time by the Medical Council.

Oxford Responsions or Moderations.

Cambridge Previous Examinations.

Matriculation Examination of the University of London.

Oxford Middle Class Examinations, Senior and Junior.

Cambridge Middle Class Examinations, Senior and Junior.

Durham Middle Class Examinations, Senior and Junior.

Durham Examinations for Students in Arts in their second and first years.

Dublin University Entrance Examination.

Queen's University, Ireland, two years' Arts' course for the Diploma of Licentiate in Arts:

Preliminary Examinations at the end of the A.B. course;

Middle Class Examinations;

Matriculation Examinations.

An Examination by any other University of the United Kingdom, equivalent to the Middle Class Examinations of Oxford and Cambridge.

4. That Students who cannot produce any of the Testimonials referred to in the Second Resolution be required to pass an Examination in Arts, established by any of the Bodies named in Schedule (A) of the Medical Act, and approved by the General Council; provided that such Examination shall be in every case conducted by a Special Board of Examiners in Arts.

I am, Sir, &c.,

THOS. HAWKINS.

Medical Registration Office,
32 Soho square, London, W., Aug. 15.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 114.)

In December, 1768, John Hunter was made a Fellow of the Royal Society, chosen entirely and expressly in acknowledgment of his scientific discoveries and researches, as yet overlooked or their importance disregarded by the public. This election preceded his brother's, which, as he was ten years older, and known ten years earlier in London, must have been highly gratifying to John in his circumstances, and, no doubt, an incentive to further exertion, and to bear up against the difficulties which hitherto had retarded his professional advancement. He did not rush precipitately before the public to obtain present distinction, since nothing was published by him until 1772,—only what in 1764 appeared, through his brother, in his absence. This reticence to challenge rashly the public tribunal and judgment was sound wisdom, and showed a tenacity for future fame. Thus, he took twenty years patiently to correct and revise the doctrines he promulgated in his lectures, before he gave them to the public. The plagiarisms and misrepresentations of the opinions he communicated, gave him annoyance and cause of just complaint.

Connection with the Royal Society afforded the earliest notice of every discovery in science, and improvement in medicine and surgery, in Europe. Honours thus spontaneously conferred, nevertheless did not exempt him from calumny and abuse. It was said he passed ten years, from 1762 to '72, of idleness, at a period of leisure, in which, if he had had abilities, he might have obtained an elementary knowledge of living and dead languages, and also of the construction of his native tongue, of which he certainly was singularly deficient. He was accused, amongst other unscrupulous and scurrilous charges, of plagiarism,—and, strangely enough, of plagiarism from the ancient Greek and Latin writers; also, of hiring writers. Jesse Foot says that "John Hunter never was the author of any production which appeared under his name. The writing part was always performed by another: he prepared the skeleton, and another covered it with composition; he formed the materials, and another made them up into dresses for the public. He was incapable of putting six lines together grammatically into English; and at his lectures was often found so far incapable of making out the sense of his own notes, as to pass over the subject they were meant to explain." Again, that "the celebrated Dr Tobias Smollett, who was one of the proprietors and editor of the 'Critical Review,' was the champion of the Hunters on all occasions when wanted." (*a*) Smollett, an unsuccessful medical practitioner, and the friend and countryman of the Hunters, took their part in the 'Critical Review' against the Monros, father and sons, in the claims for the discoveries of the injection of the tubuli testis, and of the lymphatics. In this instance, malignity stands self-revealed. Foot further taunted John Hunter with having been only five months House-Surgeon of St George's Hospital, and with total ignorance of prescribing, and of *materia medica*.

John Hunter, unknown by the public and unappreciated, without practice, in poverty, and repining at what he considered undeserved neglect and obscurity; flanked in his scientific career by a jealous and envious brother, and numerous competitors, foreign and native, the first sufficiently advanced in popularity and worldly success to look down upon John, to use, snub, control, and convert his discoveries to himself, and appropriate his labour in the preparing of specimens,—in defiance of all was elected Fellow of the Royal Society before Dr William Hunter, totally unexpected by himself, and by every one. This was rather one of those rare instances of blind justice in the dispensation of honour and reward, from its sparseness on that account worthy of record, and equally creditable to recipient, and Royal Society, of which Sir John Pringle was at that time President.

Dr Adams says, "It does not appear that Mr Hunter had offered any paper to the Royal Society till five years after his admission, when the President forced from him the only important experiments that have appeared from his hands. From that time, 1772 to '76, several of his papers were published in the 'Philosophical Transactions;' after which, till 1782, he seems to have been so much occupied in preparing for the Gulstonian Lectures, that, excepting the dissection of the Free Martin, nothing is to be met with under his name in those valuable memoirs." (*b*)

Notwithstanding their little jealousies, his brother Dr William interested himself, and, singularly, was his only patron, if he may be so designated, to obtain his election as Surgeon to St George's Hospital, in which he succeeded in 1769, in the fortieth year of his age, and the year following his election as Fellow of the Royal Society. In this position he had the opportunity of carrying out his observations, and confirming pathological doctrines.

Disputatious squabbling is unfortunately stereotyped in the traditions of the Medical Profession, so as to denote its normal condition. Injurious to individuals, and treacherous to the undoubted merits of the Profession, it denies it the position it deserves, and would claim, if asserted with better manners, and indications of better training and culture. In modern times we need only revert to the squabble between Mr Abernethy and Mr Lawrence, and the recent posthumous attack of Dr Granville, and his analysis of the practice of the late Dr Todd; both showing bad taste and want of self-respect. In these contests, the victorious party can reap only censure. Rebuke of dogmatical opinions does not imply disapprobation, or deny free exercise of candid criticism, however severe, if just. The liberalism and speculative induction which characterised the views of Mr Lawrence, at a time when the opinions of the day were unprepared and had not sanctioned their acceptance, and facts in science and natural history not then ripe, but of more recent establishment, would not have, perhaps, at this day rendered his views so subject to harsh construction and censure, if the mode of advancing them had been cautious and conciliatory, instead of incurring, by their bad taste and flippancy, the implication of ingratitude to a proved and generous friend and patron, and tendency to infidelity and materialism. A never-failing Nemesis awaits such instability, in reaction fraught with humiliation, loss of self-respect and public esteem. Mr Lawrence asserted his opinions not only with acrimony, but with singular inconsistency; painfully disappointing expectations which a manly intellectual bearing gave in his early career, aided by considerable acquirements, handsome features, and a fine figure, indicative of talent, and promising great results, but all marred by

> "Vaulting ambition, which o'erleaps itself,
> And falls on the other . . ."

"Cæsar was ambitious. If it were so, it were a grievous fault, and grievously hath Cæsar answered it."

Destiny had stamped the form and features o young Lawrence for greatness, and almost declared him the champion of a profession whose teachings are free of exclusiveness, and its policy essentially republican and liberal. He started beloved, admired, and almost worshipped; was granted length of years, great accomplishments, opportunity, patronage, and connections. Had William Lawrence been deprived of fifty years of that eventful life, he would have gone from amongst us beloved and admired. But Lawrence proved false to himself, false to his sincere early friend and master; deserted a generous cause, until the interests of a rising profession, which, from selfish instincts, he treated with contumely. In the race of young, aspiring, and eager competitors, he has found rivals

(*a*) Jesse Foot's 'Life of John Hunter,' pp. 60, 61.

(*b*) 'Memoirs of the Life of John Hunter,' by Dr Josh. Adams, p. 129.

amongst whom he will scarcely maintain his professional position: it is time "broad-fronted" Lawrence should draw his mantle around him.

The feuds between Pott, the two Hunters, and the three Monros, respecting *discoveries*, in which the gradual and simultaneous approximation of all parties ultimately left nothing to be discovered by any, were characterised by jealousy and envious assertion of priority. Experiments conducted to a certain extent by one, when made known, were carried to a conclusion by another: thus, one party claimed to have demonstrated them first in public lectures, and the other to have first published them. Baron Haller, in the midst of these contentions, maintained a dignified moderation, worthy of his name and of science: his complacent temperament practised the golden rule of *Give and take*, by which he justly obtained the larger share of distinction and approval.

On Dr Hunter's removal, in 1768, to his new residence, now completed, in Windmill street, in which he collected and arranged his museum, John, who had hitherto had lodgings somewhere in the neighbourhood of Covent garden, adjacent to the dissecting-rooms, removed to the residence lately occupied by William in Jermyn street. This house was commodious, and well situated for private practice; and he remained in it fifteen years, until the term of the lease expired, in 1783. He also resided a short time in Golden square. In this year, '68, he became a member of the Corporation of Surgeons. About this time he broke the *tendo Achilles*, in dancing. During the necessary confinement he made experiments upon ruptured tendons; he passed a couching needle some distance through the skin, and with the edge cut through the tendons upon dogs, to ascertain their mode of union: hence originates the practice of subcutaneous section. He improved upon Dr Alexander Munro's plan, who at a more advanced age had the same accident. By keeping the knee straight, compressing the muscles, and raising the heel, he was enabled to walk on the third day, and avoided keeping his bed.

At Earl's Court, Mr Hunter kept wild animals, and amused himself by showing their peculiar habits and instincts,—and thus they became familiar. The following is related of the danger he incurred on one occasion:—Two leopards left chained in an outhouse had broken from their confinement, and got into the yard among some dogs, whom they attacked. The howling alarmed the neighbourhood. John Hunter, on reaching the spot, found one of the leopards making its escape by climbing up the wall, and the other, surrounded by the dogs, immediately laid hold of them both, and carried them back to their den. The revulsion produced was such, that after they were secured, and he had considered the risk incurred, he became greatly agitated and in danger of fainting. This instance displayed the control which a courageous man obtains over savage animals.

In 1770, John Hunter received as house-pupil, amongst many others who afterwards obtained professional distinction, the celebrated Jenner; it being the custom of hospital surgeons to receive, for one or two years, pupils who had finished their apprenticeship in the country. A friendship was thus fostered between them, and the intimacy continued through life. Jenner always spoke in high terms of gratitude of his friend and master, and sent several patients to consult him from the country.

It must be named that Government, in compliance with an Act of the Legislature, erected last year (1859) a statue of Jenner in Trafalgar square, to commemorate his discovery of vaccination. In the same year the remains of John Hunter, also by an act of Government, were disinterred from their resting-place in St Martin's Church, to be deposited with every honour in Westminster Abbey; attended by his surviving relatives, and a numerous body of the Medical Profession. A subscription has been also opened to erect a statue, to be executed by Mr H. Weekes, A.R.A., and placed in the Hunterian Museum of the College of Surgeons, which has been liberally responded to. Although nearly a century has elapsed since their decease, poetic justice is done to the memories of these two eminent men, who through many years, and during their lives, were in relations of close friendship; and at the commencement, the one in the relation of master, and the other of pupil. These posthumous tributes are not the less valuable and complimentary from the acknowledgment of their claims—fully sanctioned, especially in the instance of Jenner, throughout the civilised world—having arrived late, since the appreciation, thus confirmed by time and mature judgment, stamps them with dignity, and secures to them durability.

In 1771 he published the first part of his treatise on the Human Teeth, which is a work still referred to, and not superseded by any later production. This was the only one of his works published by the booksellers; all his others were published by himself.

At this time a Scotchman of the name of Spence—a clever and intelligent man, who had risen from a humble position as barber-surgeon—was residing in Soho square, in extensive and fashionable practice as a dentist. A tale is told by those who were envious of John Hunter's fame, that he formed a connection with this dentist, who had formerly phlebotomised and drawn teeth in Gray's-inn lane amongst the poor of that district; that by the acquaintance he formed with the fashionable people who resorted to the skill of Spence, he forwarded his interests in practice. The experiments of transposing and supplanting teeth, practised conjointly with Spence, gave him the practical knowledge of the human teeth he possessed. Spence is related to have referred to the great naturalist with complacency amongst his patients, as his patron. It is also stated that this intercourse became broken by some unfortunate syphilitic inoculations occurring in the practice of transposing teeth. Of one thing in this history we believe no doubt exists—that Spence was a very ingenious, worthy man, in large and fashionable practice as a dentist; and being countrymen, both Hunter and Spence having mechanical tastes, they not unlikely cultivated an advantageous and agreeable friendship.

THE MEDICAL ACT AMENDMENT ACT.

The following is a copy of the Act which has just received the Royal Assent:

CAP. LXVI.

AN ACT TO AMEND THE MEDICAL ACT (1858).

[*6th August*, 1860.]

21 & 22 *Vict.* c. 90.

Whereas by "The Medical Act, 1858," it is provided that it shall be lawful for her Majesty to grant to the Corporation of the Royal College of Physicians of London a new Charter, and thereby to give to such Corporation the name of "The Royal College of Physicians of England," and to grant to the Corporation of the Royal College of Physicians of Edinburgh a new Charter, and thereby to give to the said College of Physicians the name of "The Royal College of Physicians of Scotland;" and to grant to the Corporation of the King and Queen's College of Physicians in Ireland a new Charter, and thereby to give to such Corporation the name of "The Royal College of Physicians of Ireland;" but provision is not made by the said Act for reserving to the said Colleges, and the Presidents and Censors, Fellows, Members, Licentiates, and extra-Licentiates thereof respectively, by their said new names, the powers, privileges, liberties, and immunities to which they are respectively entitled by their existing names, and doubts have arisen whether, in case of the acceptance by these Colleges respectively of new Charters under such altered names respectively, the said powers, privileges, liberties, and immunities would legally attach and be preserved to them, and it is expedient that such doubts should be removed: and whereas by an Act passed in

14 *and* 15 *Hen.* 8, c. 5,

the fourteenth and fifteenth years of the reign of King Henry the Eighth, intituled "The Privileges and Authorities of Physicians in London," certain letters patent, dated the twenty-third day of September, in the tenth year of the reign of his said Majesty, whereby certain Physicians in London therein named were incorporated by the name of "The President and College or Commonalty of the Faculty of Physic in London," were ratified and confirmed; and by the said Act it was enacted, that the six persons named in the said letters patent, and two more of the said Commonalty to be chosen by them, should be called Elects, and that the said Elects should yearly choose one of them to be President of the said Commonalty, and that as oft as any of the places of the said Elects should become void the survivors should choose and admit one or more, as need should require, of the said Faculty to supply the number of eight persons, and that no person should from thenceforth be suffered to practise in Physic through England until he be examined by the said President and three of the said Elects, and have from them letters testimonial, except he be a Graduate of Oxford or Cambridge: and whereas the main function of the said Elects, viz., that of examining and granting letters testimonial, has been virtually superseded by the said Medical Act, and they have ceased to grant letters testimonial in accordance with the provisions contained in the last-recited Act; and it is therefore expedient that the before-recited provisions should be repealed: be it enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

Interpretation of Terms.

I. The expression in the Medical Act and this Act, "The Corporation of the Royal College of Physicians of London," or "The Royal College of Physicians of London," shall be taken to denote the Corporation of "The President and College or Commonalty of the Faculty of Physic in London."

New Charters may be granted to the Colleges.

II. Any new Charter which, under the provisions of the Medical Act, shall be granted to the Corporation of the Royal College of Physicians of London, may be granted to them either by and in the name of the Royal College of Physicians of London, or, as provided by that Act, by and in the name of the Royal College of Physicians of England; and any such new Charter granted to the Corporation of the Royal College of Physicians of Edinburgh may be granted to that College either by and in its present name, or, as provided by the Medical Act, by and in the name of the Royal College of Physicians of Scotland; and any such new Charter granted to the Corporation of the King and Queen's College of Physicians in Ireland may be granted to that College either by and in its present name, or, as provided by the Medical Act, by and in the name of the Royal College of Physicians of Ireland.

Colleges to retain all existing Rights, notwithstanding change of name.

III. The granting of new charters to the said Corporation respectively by and in the altered names and styles respectively, as provided in the Medical Act, shall not, in respect of such alteration of name or style merely, alter or affect in any way the rights, powers, authorities, qualifications, liberties, exemptions, immunities, duties, and obligations granted, conferred, or imposed to or upon, or continued and preserved to the said Corporations respectively, and the respective Presidents, Censors, Fellows, Members, and Licentiates thereof, by the respective Charters and Acts of Parliament relating to the said Corporations respectively; or by the Medical Act, the Act to amend the Medical Act, the Medical Acts Amendment Act 1860, and this Act respectively; but the said Corporations respectively, and the respective Presidents, Censors, Fellows, Members, and Licentiates thereof, shall, notwithstanding any such change of name and style, have and retain all such and the same rights, powers, authorities, qualifications, liberties, exemptions, and immunities, and be subject to all such and the same duties and obligations, as if such new Charters respectively had been granted to them by and in their respective names and styles as then existing.

Colleges to hold Property, notwithstanding change of name.

IV. Each of the said Corporations shall also, notwithstanding any such alteration of name or style, have, hold, and enjoy, and continue to have, hold, and enjoy all lands, and other real and personal, heritable and moveable property belonging to such Corporation, either beneficially or in trust, at the date of the granting of such new charter, and may execute and perform any

use or trust for the time being vested or reposed in such Corporation.

Provisions in 14 and 15 Hen. 8, c. 5, as to the Elects, repealed.

V. So much of the Act of the fourteen and fifteen Henry the Eighth, chapter five, as relates to the Elects of the said Royal College of Physicians of London, and their powers and functions, shall be and the same is hereby repealed, but this repeal shall not prejudice or affect the rights and privileges of any persons to whom the said President and Elects may have granted letters testimonial; and all trusts which, by any deed, gift, devise, or bequest are vested in, or to be executed or performed by the Elects, or some defined number of them, shall vest in and accrue to, and be executed and performed by the Censors of the said College for the time being, as if the name of the Censors had in such instruments respectively been used instead of that of the Elects, and the office and name of Elects of the said College shall henceforth wholly cease and determine.

Election of the President of the Royal College of Physicians of London.

VI. The office of President of "The Royal College of Physicians of London" shall be an annual office; and Thomas Mayo, Doctor of Physic, the now President of the said Corporation, shall remain such President until the day next after Palm Sunday in the year 1861, when he shall go out of office; and the Fellows of the said Corporation shall, at a meeting to be holden by them for that purpose, on the same day, and on the same day in every subsequent year, elect some one of the Fellows of the said Corporation in such manner as shall be provided by any byelaw or byelaws made in that behalf by the said Corporation, and for the time being in force, to be President of the said Corporation, but the retiring President shall always be capable of being re-elected, and every President shall remain in office until the actual election of a new President; or in case of death, resignation, or other avoidance of any such President before the expiration of his year of office, the said Fellows shall, at a meeting to be holden by them for that purpose, as soon as conveniently may be (of which due notice shall be given), elect one other of the Fellows of the said Corporation in such manner as aforesaid to be President for the remainder of the year in which such death, resignation, or other avoidance shall happen, and until such election the duties of President shall be performed by the Senior Censor for the time being.

BRITISH MEDICAL ASSOCIATION.

THE DISCUSSION ON SPECIAL HOSPITALS.

Dr Thudichum rose to propose a resolution in connection with Special Hospitals, and, in doing so, confessed that he wished it had fallen into other and more able hands. But he believed there was a peculiar qualification for him, that he was neither connected with a General or Special Hospital. He believed that the majority of members of the Association had read, as he had, with great regret, and perhaps some had with surprise, a document which had emanated from some of the highest of the Profession. [The document in question was the Protest, a copy of which was published in this Journal for Aug. 1, p. 82.] This document was a protest in emphatic language against certain institutions, the mode and object of which were to divide particular cases in particular Hospitals for alleviating human suffering, and for the advancement of Medical science. He believed the members would give due weight to the importance of this protest. In the first instance, let them consider how that protest was obtained. It was by gentlemen who were particularly opposed, for personal reasons, to the establishment of one particular institution. He would not say that it was jealousy which called into operation this activity. The protest was directed against Special Hospitals in general. From this protest they excepted only those Hospitals which were for treating the diseases of the eye. All Hospitals were included which conferred immense benefit for treating consumption, &c.; and consumption was a disease excluded from all but a small portion of the General Hospitals. These diseases were excluded from their common Hospitals. Then there were other diseases. A great many cases of chronic cancer were by the rules of General Hospitals excluded, together with epilepsy, &c. Yet all those Hospitals which were for their particular treatment were opposed or objected to in this protest. He knew fully the objections which might be brought against them—that they were for certain purposes, for personal aggrandisement; that they were instituted for the purpose of bringing money and influence to those Medical Officers who were connected with them. It was also objected against Special Hospitals, that it was impossible for them to serve the cause of education. The student would lose half of his time in passing from one to the other. It had been also objected, that gentlemen who treated specialities were not always the best qualified to treat specialities, but that it was requisite for them to know the whole arrangement of Medical science. That was true. He believed there was not any one gentleman connected with Special Hospitals, or who practised speciality, who did not claim and really possess a knowledge of general Medical science. Again, how could it be proved that, because these gentlemen practised some speciality, they did not possess a knowledge of general Medical science? Until that was proved, he could not admit on that ground that Special Hospitals were objectionable. But there was one great reason for the establishment of Special Hospitals. Their General Hospital were established, in the first instance, for the relief of the sick poor. That was the first object of all Hospitals. In many cases, it afforded opportunities to Medical students and Medical men of studying diseases and the cure of diseases. He spoke especially of Metropolitan Hospitals, where, as in others, these different objects were attempted to be obtained. But it was almost impossible for these objects to be obtained in the way in which they were attempted. Then, in the large Hospitals, the Physician had to see the patients under his care, and prescribe for them, although they might amount to a considerable number. There was also a most numerous class of most honourable men, well known in science, who would make very good use of their time, if they had the opportunity to show their skill and perseverance. These gentlemen were excluded; and a vast amount of talent, which was excluded from General Hospitals, was taken in by Special Hospitals. The establishment of Special Hospitals might be called a "necessary evil." (A laugh.) Let the number of subscribers to General and Special Hospitals be compared. They were nearly equal. If the amount of money subscribed to General and Special Hospitals were compared, he believed the advantage would be found in favour of Special Hospitals. The number of beds and the accommodation afforded to the sick poor in Special Hospitals and in General Hospitals would be found almost equal. If the benefits which Special Hospitals conferred upon the poor were compared with those conferred by General Hospitals, in this instance they were almost equal. A sweeping combination, therefore, against Special Hospitals, he should very much regret. But when the combination came from such high authorities as those gentlemen who signed the protest, he was afraid that, if the members of the Association did not throw themselves into the breach, very great damage might be done to Special Hospitals. What was the issue at which he arrived? He believed that Sir Charles Hastings, in signing this protest, had a twofold object: first, to advance as far as possible Medical education; and, in the second place, to preserve for the purpose of Medical education those establishments which were especially devoted to it. He believed there was no man in this country who had more at heart a desire to improve Medical education than Sir Charles Hastings. (Hear, hear.) He was certain that Sir Charles Hastings was far from intending any injury of any kind, or passing any reflections upon Hospitals which conferred benefits upon patients who were excluded from the Ordinary Hospitals, and which offered a field for the researches of gentlemen who were excluded from General Hospitals. He knew by this time that one very eminent member of the Profession regretted having signed the protest. The issue was this—that when General Hospitals would reform, Special Hospitals would cease. (Hear.) The resolution which he was going to move, he believed Sir Charles Hastings himself, after having signed the protest, would not object to second. It was intended to be a mediative resolution, to mediate between two parties, which he was afraid were now separated. Let the Associates throw themselves into the gap and stop the breach, both in the name of the public and of the sick poor. The following was the resolution which he wished to propose:

"That this Association observes with great regret the difference of opinion in the Profession on the subject of Special Hospitals. That, while it cannot but express that the existence of Special Hospitals is attended with many disadvantages, the abolition of such Hospitals is impossible until there is a great reform in the public and Professional management of the General Hospitals."

A MEMBER asked the President if it could be so arranged that each speaker who spoke should not occupy more than five minutes.

The PRESIDENT had suggested that proposition in the Journal about six weeks ago, but he was sorry to say that he had received nothing but private communications in reference to the point.

Sir CHARLES HASTINGS thought five minutes quite sufficient.

After a short discussion, it was agreed that each speaker should only occupy five minutes.

Dr ROUTH (London) said that he would just enumerate some of the Hospitals which were at present taken up by Special men, and he would ask the members present, simply as men of common sense, whether it was possible in the arrangement of the Profession that these could be set aside upon the request of any men, however excellent. There were Lying-in Hospitals, Children's Hospitals, Eye Hospitals, Skin Hospitals, Epileptic Hospitals, Consumption Hospitals, Smallpox Hospitals, Fever Hospitals, &c. Would any man of common sense venture to assert that in any General Hospital any of these particular diseases could be treated as specialities? He could not follow his friend Dr Thudichum in declaring himself not to be a Specialist; but irrespectively of this, he would ask the meeting, for instance, to consider the diseases of women. In some General Hospitals they had three or four beds; but what were three or four beds in large Hospitals compared to vast multitudes of women? To tell him that because the people saw the benefit of Special Hospitals, and also the efficiency of those Hospitals for special subjects for which they were instituted, these Hospitals were to be done away with, seemed to him to be quite an opposite proceeding to that which ought to be followed. In Special Hospitals there were large numbers of the same kinds of disease. Instead of three, four, five, or six, there were fifty, a hundred, or two hundred patients. The Medical attendant could, therefore, reason on all of them. This was the way to come to general conclusions. No man could come to any positive conclusion as to the treatment of special diseases till he had had many examples. The remarks he had made came close upon the five minutes, although he could wish to have extended them. But he would simply put the matter to them as men of common sense; and in reference to Specialists, why their President was a Specialist! They all knew that he particularly devoted himself to the investigation of pulmonary consumption. They know that in all their Hospitals, especially so in London, these cases were excluded, and they could not, if they would, get in a consumption case. (Hear.) Then let them look at Dr Brown-Séquard; the fact of him being a Specialist had brought him to this country. It was because he understood, more than the generality, the subject of epilepsy, that he had come forward. He hoped that his example would result in great advantage to the public. (Hear.)

Dr RICHARDSON said that in 1854 he wrote a series of articles in the Journal on the subject, in which he had as thoroughly condemned Specialities as any of the modern protesters. Since that time he had served an apprenticeship of nearly seven years at a Special Hospital; and his opinion remained unchanged. At the same time, he could not accept the manner in which the protest had been brought forward. He believed it fair to assert that Special Hospitals at first originated out of sheer charity towards those sick who were excluded from General Hospitals; such as fever cases, lying-in cases, diseases of women, the

diseases of children, phthsis, cancer, and epilepsy. Thus the Special Hospitals were established to supplement so-called General Hospitals, which were in fact Special. Why this tumult against Special Hospitals? Because some thought that they trenched on the supposed duties of General Hospitals. Now, that abuses had crept into the Special system was certain; but these had existed for years, and had not been criticised by any protest of a general kind. Why not? Because the Special Hospitals had not interfered with the General. But the moment that a Special Hospital was set up, which took in cases acceptable to the General Hospitals, that moment it was discovered that Special Hospitals were injurious. On the public side of the question, he asserted that such a decision was neither logical nor just. But there was also a professional side to the question even more important. When a young man settled in London, and saw the great field for professional exertion, he naturally yearned to participate in the labour, and to advance not himself only, but his profession. But if such an one did not choose for many years to hang on to an institution with the chance of being a full officer at sixty, or if he had not some powerful extraneous influence, he could never get into work at the General Hospitals, and was therefore by necessity, and even against his tastes, driven into the Special Institutions; and such was the main reason why such Institutions were supported by Medical men—a support which would at once be withdrawn if the overwhelming labours of the General Hospitals were equalised and utilised. In conclusion, Dr Richardson said that he believed that he had learnt a great deal in a Special Hospital. He would, however, give up his post to-morrow if he saw an indication of liberal reform in the greater Institutions; meantime he could not allow the present opposition to go forth without speaking what he thought about it, which was, that, traced to its primitive root, it carried with it a vast amount of selfishness, exclusiveness, and (he must add the word) hypocrisy.

Dr Markham agreed with a great deal of what had been said by the speaker who had preceded him, but could not go the whole length with him. He thought that he had taken the matter up on much too personal grounds. He would put it as a matter of principle. He would, in one sense, second Dr Thudichum's proposition. He admitted that some evils which existed with respect to Special Hospitals, were carried on also in General Hospitals. With regard to the origin of Special Hospitals, he believed they arose in a matter of self-interest. (No, and Yes.) Gentlemen had started these Special Hospitals for their own private purposes. (No, and Hear.) The great bulk of the Special Hospitals in London were established for one simple reason by Medical men, for their own special purposes. (Cries of "No, no," and "Yes, yes.") He asserted the fact without any fear of contradiction by those who knew the matter well. He belonged to an Hospital for many years, and he said that they were got up solely and simply for the interest of private individuals. He would say that all Hospitals, and the whole medical charitable system, was founded on an utterly wrong basis. He wished that the Association could appoint a Committee to investigate and report upon the condition of their Hospital and Dispensary Medical system. That would draw the question away from personal considerations. He confessed that he believed their Hospital system was at the root of the great evil that affected their social system. Those who knew what was going on at this moment knew that they were abused to an incredible extent. But this was not only in London, but elsewhere. It affected the Profession in every part of England, and was widening with the extent and growth of these Special Hospitals. The evil was there more distinctly shown than in General Hospitals. But in all Hospitals it was excessive. The first and proper objects of charity, were the poor and labouring classes. There were two other great classes,—paupers, and well-to-do citizens. There was imposed upon Medical men in General Hospitals a robbery upon their services, but he would say that in Special Hospitals the robbery was going on to an extent fifty times more. A gentleman being asked to operate on a patient, said that his fee was fifty or sixty guineas. That sum he merely mentioned for argument. The patient's medical attendant said the patient could not give it; but the Surgeon could not take a farthing less than sixty guineas. But, he said, if the patient came into his Hospital, he would operate on him for nothing. (Disapprobation.) Look at the Special Hospitals, and see what they did. The Special Hospitals took in all England, while the General Hospitals were generally limited to their own districts. In Special Hospitals there were crowds of patients who came from every part of England. Could the gentlemen engaged in these Hospitals investigate their circumstances? Could they tell whether they could pay their own Practitioner? It was true that the gentlemen engaged in these Hospitals got their names spread all over England, but in the mean time the Profession was being ruined. He knew another instance. A gentleman, who was able to give his daughters 15,000*l.*, put himself under one of their Profession, who asked him 40*l.*; but this gentleman dressed himself as a poor man and got the operation done for 5*l.*! How were they to look for reform? There was only one way. It must be through the public; and the public knew nothing of what was going on in this matter. He was perfectly satisfied that if they knew it, they would not permit it. (Hear.) He would, therefore, ask the Association to appoint a Committee to investigate the whole subject—to state what were the best grounds on which Hospitals ought to be established, their proper objects, how these could be best carried out, and to propose a remedy. Such a report, accepted by this Association, and published to the world, would, he was certain, have an immense effect upon the charitable public of this country. They would know what was wanted. He believed that it was most important that they should issue a report, stating the proper objects of charity, and how it was best to carry out charitable objects. He, therefore, proposed the appointment of a Committee, whose business it should be to investigate the present condition of the Medical system, and to report upon it at the next meeting of the Association. He hoped it would go forth to the world, and then the charitable public, wishing to know what they had better do, would have the solemn report of the British Medical Association. He proposed —"That a Committee of twelve be appointed to investigate the whole question of Hospital management throughout this country, and to report upon it at the next annual meeting."

Sir Charles Hastings seconded the amendment, which he believed was the only solution of the difficulty. He was one of those "hypocrites" who signed the protest. (A laugh.) But he was not aware that he was hypocritical, nor could he believe that any who did sign it were open to the imputation. He thought it was not well to assign motives to gentlemen. There should be a good feeling among members of this Profession, and hard names should not be used. He thought, with Dr Markham, that the present system of Hospitals was a gigantic evil in the sense in which he signed the protest. But he did not find in the protest the words which were said to be in it, that there were to be no Special Hospitals. There was no such thing in the protest. He thought a good deal of good would arise from the protest. He was glad to have had an opportunity of signing it, if it led to the formation of a Committee. He trusted the Committee would give a good, solid report.

Dr Stewart (London) said that the subject of their dispensary system had occupied his attention for the last fifteen years. He thought the evil was great, socially, and a very grievous wrong to the Medical Profession. He had great pleasure in supporting the amendment. The evil was become of such magnitude, that it required some strong measures. With regard to the specialities, there were the Skin Hospitals, the Small-pox Hospitals, and the Consumption Hospitals. Consumption, it had been well said, was a special case, because the air of their General Hospitals was such that consumption cases became rapidly worse. He (Dr Stewart) thought there was a debt of gratitude due to their editor (Dr Wynter) for the manner in which he had brought forward the subject of Special Hospitals. He had done so with spirit and talent, and in a manner which had set the public talking about it. He believed that it had something to do with the stir which had taken place upon the subject. As an Association, they owed him thanks for the part he had taken. (Hear.)

Dr Edward Smith (London) thought that these resolutions should be taken separately. He took it that Dr Markham's might stand by itself. He thought the meeting could unanimously concur in the resolution, provided that the Committee was particularly selected. With regard to the origin of Special Hospitals, he did not believe that there was any more selfishness in their origin, than in that of the General. The originator of the Brompton Consumption Hospital was a Mr Rose, a lawyer. There was not a Medical man associated with the question. The origin was purely voluntary. While, therefore, he said that Hospitals were established for self-interest, it did not apply to all, and certainly not to his own. When Medical men went to Paris to complete their education, did they spend their time by going where they could see a large variety of cases? They went to the Special Hospitals—one for the skin, another for children, &c. This was an advantage. Another complaint which they heard was the habit of some Medical men seeing their patients at home gratuitously. He knew a gentleman, occupying a high position, who saw patients at home, and charged them half-a-guinea, if they could not afford to pay a guinea; and in some instances, where they could get nothing more out of them, they sent the patients to the Hospital. In conclusion, he did not see why they should reflect on the management of General Hospitals.

Mr Hutchinson (London) hoped that the matter would stand over for a year, when they would be able to arrive at a better conclusion than if they came to any sudden resolution at the present moment. He should like, if the Committee were appointed, for it to recommend strongly upon General Hospitals having specialities in connection with them. He hoped Dr Markham would let his suggestions be put as an amendment.

Dr Richardson explained that, in using the terms "selfish" and "hypocritical," he did not use them with regard to the gentlemen signing the protest—(Hear, hear)—but only as to the mode in which the protest originated. That was a very different question, and he hoped Sir Charles Hastings would accept the explanation.

Mr Southam (Manchester) thought that the system of speciality had become such an abuse, that the Associates ought to do what their friends in London did—express their opinions as to the propriety or impropriety of going on with these establishments. Could they suppose, as they had been told, that the gentlemen signing this protest had interested motives? It was impossible to suppose it. They had seen, no doubt, that the public, as well as the professional Practitioner, had witnessed the injury of speciality in the Profession. He believed, if these gentlemen had thought speciality better than generality, not one of them would have signed it. (Hear, hear.) He thought they should do something to the same effect as had been done in the metropolis, that Special Hospitals were detrimental. He would propose a substantive resolution.

Sir Charles Hastings hoped that Mr Southam would not do it.

Mr Southam said that his opinion was, that Special Hospitals were detrimental to the Profession. He believed there were few Physicians who were not annoyed by the special gentlemen. He could adduce a number of instances of the kind, showing how their patients were annually drawn away from them, under a pretence. He thought they should say something with regard to these Special Hospitals. If the Committee were to express its opinion on speciality, he had no objection to withdraw his proposition; otherwise he should press it.

Dr William Budd (Clifton) remarked, that there could be no doubt that there must be Special Hospitals—for small-pox, for instance; but he always looked upon Special Hospitals as necessary evils. He thought the only ground on which cases should be treated in Special Hospitals was, that there should be something inherent in the nature of these particular diseases rendering it necessary that they should be special, and excluding them from General Hospitals. This appeared the only ground for Special Hospitals. But there were several things inherent in the nature of some of these specialities which constituted a great drawback. The great class of infectious diseases were dangerous to the attendants. He believed statistics would prove a large mortality among those giving assistance in these Special Hospitals. No one could estimate the importance of having a

person of such distinguished ability as Dr Brown-Séquard. (Hear). But he must confess that he thought the diseases of the nervous centres were the last that should be brought together, especially when the diseases produced paroxysms frightful to witness. He thought it necessary to make these remarks on behalf of the Physicians and Surgeons of General Hospitals, of whom he had the honour to be one.

Dr Brown-Sequard (London) said he hoped they would have an opportunity of finding out what he had said to be true, that when cases of epilepsy were received into General Hospitals, he would resign his situation at once.

Dr Vose (Liverpool) could not help entering his protest against the way the debate had taken. He thought it of the greatest importance to avoid invidious comparisons. After alluding to the different diseases which they were told should be specially dealt with, he said that he thought there should be some limitation to this subject.

Dr Thudichum would not further enter into the merits of the case. That morning he had entered into an arrangement with Dr Markham by which his present amendment was to follow his resolution as a rider. He was, therefore, rather astonished. (A laugh). He felt confident that inquiry would report the case to be ten times worse than he had represented it. He had great pleasure in withdrawing his resolution. He had no doubt that if the Committee was formed on a basis—and he made that the condition on which he withdrew his resolution—it would confer upon them greater benefit than if his proposition had been carried. (Hear, hear.)

After further remarks, the President put Dr Markham's resolution, which was carried. The formation of the Committee was deferred to the next day.

OUR NOTE BOOK.

ON THE MORTALITY OF INFANTS IN THE MOSCOW FOUNDLING HOSPITAL.

Dr Blumenthal, Senior Physician to the Moscow Foundling Hospital, the largest establishment of the kind in Europe, in this paper passes in review the various causes which favour the mortality of the inmates of that institution.

1. The first point he notices is the miserable condition in which most of the infants are, the fruits of concealed and illicit connexions, their mothers often undergoing great privations during the period they bore them. In conformity with the experience of all countries, the mortality of illegitimate far surpasses that of legitimate children. Moreover, owing to the central position of Moscow, these children are brought from a large radius, and often only reach the establishment days after their birth, frequently exhibiting various signs of neglect and severe injury. Thus in the year 1856, one of mean mortality, of 11,762 infants admitted, 135 died within the first 24 hours after admission, 280 did not survive the third day, 238 were premature, and 1,268 exhibited well-marked atrophy, giving a total of 1,921, doomed to speedy death independently of the action of other causes of mortality to be found within the walls of the hospital.

2. One of the greatest evils is the occasional deficiency of nurses. At certain times of the year, especially in summer, the nurses are obliged to leave the establishment to resume their field labours, and a number of children are deprived of their breasts, and have to be distributed among the diminished number of nurses who remain. In spite of the addition of artificial food, the infants become the subject of various diseases, especially of atrophy. The most careful efforts have been made to supply the necessary nutriment by means of the milk of cows kept with the greatest care at the establishment, their milk being administered by means of the sucking-bottle, and complete watchfulness and cleanliness insisted upon—but all in vain, the infants fast sinking under diarrhœa, or perishing from atrophy with enteritis. On the other hand, when, after a defective supply of nurses, these women return again in numbers sufficient to give each deprived infant its new nurse, it is found that the number of diseases and the amount of mortality soon undergo an increase. This arises in part from the eagerness with which the hungry infant takes the rich milk of the new breast, and in part from the sudden change of nurse and milk.

3. The Author regards the change of nurses, which the arrangements of the establishment renders unavoidable, as a great evil for the infants, even when the milk they continue to obtain is sufficient as regards quantity, such change becoming, even in healthy, thriving children, frequently a cause of sudden and severe disease.

4. The next cause assigned by the Author is founded upon a somewhat fanciful idea, viz., that disease is generated, not merely by the fact of a conglomeration of individuals, but especially when such individuals are of foreign and varied origin—a kind of, so to speak, human acclimatisation being necessary to produce exemption. This he exemplifies by the breaking out of disease on the passage of healthy troops through healthy districts of an enemy's country, &c.—facts explicable on more probable hypotheses. In the Moscow Hospital the 13,000 children and 13,000 nurses annually brought together are derived from the most opposite regions and different conditions of life; and these numbers are constantly going and returning, so that the daily 12,000 children and nurses are being made up continually of different individuals.

5. Next, we have the more tangible cause—overcrowding. The number of admissions is so rapidly on the increase, that while during the ten years 1764-74 there were only 9,457 infants admitted, this number had risen to 90,184 during the ten years 1844-54, and continues to increase even still more rapidly. The building not having been proportionally enlarged, the air, in spite of every attempt at ventilation and the most anxious endeavours, becomes excessively deteriorated, especially at night.

6. Epidemic visitations exercise but little direct influence on children at the breast. It is true that towards the end of winter and the spring, catarrhal and inflammatory affections of the respiratory organs prevail; while in the summer and autumn diarrhœa and inflammatory conditions of the abdominal viscera are frequent. But any prevailing epidemic which may be affecting the general population exerts very little influence on the health of these infants. Thus, during his nine years' superintendence of the establishment, the Author has not met with a single case of scarlatina, although, during this period, the disease has frequently prevailed in the town, and has even attacked other inmates of the establishment. Isolated cases of measles have alone been met with; and although instances of varioloid and varicella have been of more frequent occurrence, they have never taken on any extension. When cholera or ague have been prevailing in the town, they have been only met with exceptionally and in isolated cases in the hospital. Small as is the direct influence of epidemic visitations upon these infants, the Author feels convinced that their indirect influence is not insignificant, by reason of the injurious effect they exert upon the mother during pregnancy. Thus, when ague or cholera have raged epidemically, or when the *genus morborum* has given rise to diseases characterised by depravation of the blood and disposition to purulent formation, the children admitted have been especially feeble and miserable.

Such, then, are the circumstances which chiefly favour the mortality of the establishment. It is remarkable, however, that while these causes are more or less stationary, the amount of mortality occurring among these infants undergoes considerable variation, two successive years scarcely ever resembling each other in this respect. During the thirty years 1829-58, it has varied from 15·42 to 32·09 per cent.; but repeatedly decreasing or increasing within these limits. Yet more, the mortality has never on one occasion been in an exact proportion to the amount of disease. Thus, while in 1851 the percentage of disease was 64·62, that of mortality was 25·77; but in 1857 the percentage of disease was 56·54, and of mortality 32·09. In the years 1855-56 the percentage of disease was almost alike, but there was almost 5 per cent. difference in the mortality: and in the years 1857-58 a difference of about 1 per cent. in disease was accompanied by one of 8 per cent. in the mortality. The year 1854, which furnished so favourable a percentage of mortality as 16·64, exhibited the high percentage 51 of disease. It is evident that mortality depends upon other causes than the mere production of disease. Dividing the last thirty years into three categories accordingly as a minimum, medium, or maximum mortality prevailed, the Author finds that each of these nearly embraces the ten years; but although convinced that these variations in amounts of mortality depend upon some general cause, he is quite unable to indicate its nature.

For an exact appreciation of the rate of mortality in the hospital, it would be very desirable to compare it with that of other children of the town of the same age—viz., two months, this being the average age at which the infants are sent from the establishment to the village nurses. The materials for such a comparison, however, do not exist. An approximative comparison the Author has attempted from an examination of the St Petersburg and Moscow registers, at least as regards a large proportion of births. In the ten years 1847-56, of 138,626 infants born in St Petersburg, 34,746 died within the first year, giving a mortality of 25·05 for that first year; while in Moscow, for 95,272 births there were 25,953 deaths, or 27·24—the mortality in both cases being, in the Author's opinion, actually greater. Endeavouring to separate from these figures the mortality which affected only the two first months of life, by supposing the proportion to be similar to that furnished by the Belgian tables, the Author deduces that such mortality is 13·46 for St Petersburg, and 14·64 for Moscow. But these figures relate only to legitimate children, who are not only conceived and born under so much more favourable circumstances, but are provided afterwards with all the advantages of a mother's care. To bring the two conditions at all to an equality, judging from tables which have been published for Prussia and elsewhere, at least from 6 to 8 per cent. must be added to the mortality, which would raise the mortality to be expected in the hospital to from 20 to 23 per cent. And such is the fact; for of 245,184 infants admitted between 1829-58, there have died 55,602, or 22·27 per cent.—'Med. Zeit. Russland,' 1859, Nos. 30, 31, and 'Medical Times and Gazette.'

CANCER OF THE BREAST. — INTERNAL TREATMENT RECOMMENDED BY PROFESSOR VELPEAU.

In the case of a stout, lymphatic woman, most probably affected with lardaceous medullary sarcoma of the breast, with suspicious swellings in the axilla, M. Velpeau, unable to persuade the patient to submit to an operation, prescribed the following medication:

1. To take, night and morning, in a cup of infusion of hops, a tablespoonful of

Aq. destill . . .	16 oz.
Potassæ hydriodat. . .	2½ dr.
Tinct. conii . . .	1½ dr.

2. To drink at meals the mineral water of Bussang or Condillac mixed with wine.

3. Every eight or ten days to take, as an aperient, a bottle of Seidlitz water.

4. To take twice a week an alkaline bath.

5. Morning and evening to anoint the breast with a mercurial ointment containing iodine.—'Journal of Practical Medicine and Surgery.'

ESCHAROTIC GUTTA-PERCHA AND CHLORIDE OF ZINC ARROWS.

The amalgamation of gluten powder with chloride of zinc has fully answered the expectations of the inventors, particularly in cases of naso-pharyngeal polypus. But when it is necessary to insert these arrows into sinuses, they do not preserve their rigidity, and the softened caustic soon becomes a foreign body, which the surgeon has to extract piecemeal. M. Somme, first-class apothecary, in order to obtain harder and equally powerful cylinders, substitutes gutta-percha for gluten.

The preparation of this new escharotic, says the 'Journal de Chimie Médicale,' is of the simplest. The gutta-percha should be softened in boiling alcohol, and incorporated, in a heated porcelain mortar, with the chloride of zinc finely powdered. A mixture of equal parts of the ingredients is thus effected, which is rapidly rolled on a marble slab into cylindrical sticks pointed at their extremities; these are at once enclosed in well-dried phials with wide necks, filled with powdered quicklime and hermetically sealed.—'Journal of Practical Medicine and Surgery.'

ON THE DISEASES OF PRINTERS.

Dr Van Holsbeek having enumerated the diseases resulting from overwork, from intemperance, want of cleanliness, vicious habits, protracted watching, &c., proceeds to speak of the morbid affections more specially belonging to the printer's art. Fissures of the lips, of varying depths, are of frequent occurrence; at other times tumours are developed on the inner surface of the same parts, which are nothing else than follicles whose excretory ducts are closed. These tumours sometimes inflame, become highly painful, rapidly ulcerate, and assume a cancerous appearance. Such affections of the lips are owing to the habit some compositors have of putting into their mouth the types still moist with the fluid which has served to wash them. Dyspepsia is frequent, as is diarrhœa; the latter is, however, of a transitory and mild nature. Among the most common affections are those of the respiratory passages, of which laryngitis and bronchitis are the principal; pleuritis is rare; pleuropneumonia is frequent and severe. These diseases are favoured by the curved position which the printers are obliged to maintain during their work, particularly when they correct on the forms, and still more by the night-work, by gas-light, by the dust and emanations in places often confined and badly ventilated. Nearly twenty-five per cent. of printers die of tuberculosis, either hereditary or acquired. Diseases of the heart prevail among the pressmen; hæmorrhoids are rare; varices and varicose ulcers are of frequent occurrence; the compositors who correct on the form frequently suffer from cerebral congestions and hæmorrhage. Among nervous diseases we observe tremor of the hands, against which the Author successfully employs the electric current. Saturnine colic and paralysis are rarer than formerly; an improvement due principally to the difference in the composition of the materials of which the type is made, to the precaution of cleaning it from dust, as well as frequently rubbing the boxes which contain it: lastly, to the care of the workmen, who no longer put the letters in their mouth. Hernia is common, particularly among the pressmen; in them we occasionally observe distortion of the joints of the fingers. Fissures and callosities form on the thumb and index finger of the right hand, on account of the roughness of the characters, particularly if they are new and damp with the matters with which they are polished; moreover, in consequence of the habits the printers have of washing themselves with alkaline water or bad soap. Amblyopia and myopia, so very prevalent among typographists, terminate the sketch drawn by the Author of the diseases of this interesting class of artisans, with whom we are in daily contact, and whose intelligence and diligence we have constant reason to admire.—'Lo Sperimentale,' December, 1859, p. 560, and 'Dublin Quarterly Journal.'

Births, Marriages, and Deaths.

BIRTHS.

Howison.—August —, at Cambo, Northumberland, the wife of James Howison, Surgeon, of a son.

Kirby.—August 13, at Taviton street, Gordon square, the wife of E. A. Kirby, M.D., of a daughter.

Taunton.—August 13, at St Austell, Cornwall, the wife of W. Taunton, M.D., of a son.

MARRIAGES.

Gamgee.—Parker.—August 9, at the Parish Church, Handsworth, Joseph Sampson Gamgee, Esq., M.R.C.S., Surgeon to the Queen's Hospital, Birmingham, to Marion, second daughter of the late William Norton Parker, Esq., of Edgbaston.

Ransom.—Bramwell.—August 14, at the Parish Church, Tynemouth, William Henry Ransom, M.D., of Nottingham, to Elizabeth, daughter of the late William Bramwell, Esq., of Dockwray square, Tynemouth, Northumberland.

Sedgwick.—Rossi.—August 2, at Marylebone Church, Samuel Jarvis Sedgwick, Esq., eldest son of Samuel Sedgwick, M.D., of the Island of Antigua, to Selina Hanna, second daughter of Louis Rossi, Esq., of St John's wood.

DEATHS.

Fosbrooke.—August 2, at Loughborough, Leicestershire, Edward Fosbrooke (in practice prior to 1815), in his 90th year.

Meggison.—August 3, at Bolam Vicarage, Dr J. N. Meggison, aged 41.

Mott.—August 13, at Church Stretton, Shropshire, aged 70, Mary Jane, wife of Charles Mott, Esq., M.R.C.S.

Parsons.—July 21, at New York, Henry L. Parsons, M.D., aged 39.

Thomas.—August 4, of consumption, David Thomas, of Trefigsi, Llandilo, Medical Student at the London Hospital, aged 28.

Thompson.—August 11, at the house of his sister, Vale Lodge, Sutton, Surrey, Theophilus Thompson, M.D., F.R.S., of Upper George street, Portman square, aged 53.

Towle.—June 28, at the Island of St Thomas, West Indies, on his passage home. William Henry Towle, of Nuneaton, Warwickshire, M.R.C.S. Eng., aged 25.

Trotter.—August 4, at Summerhill, County Meath, David Trotter, F.R.C.S. Ireland, aged 66.

Wilson.—August 6, at Terally, Kirkmalden, Robert Wilson, M.D.

Wright.—June 17, at Ootacamond, East Indies, Senior Apothecary John Wright, late in Medical charge of Vingoria.

MEDICAL NEWS.

Apothecaries' Hall.—The following gentlemen passed their examination in the science and practice of Medicine, and received certificates to practise, on Thursday, August 9th, 1860:—Frank Harvey Browne, Stowe Maries, Essex; James Howard Clarke, Gerrard street, Soho; Henry Boothby Dow, Hanwell, Berkshire; John Jones, Tir Bach House, Llanelly; William Jas. Mallett, Bolton-le-Moors; George Henry Strutt, Tutbury, Staffordshire.—The following gentlemen also on the same day passed their first examination:—James Appleyard, London Hospital; Charles Ballard, Guy's Hospital; John Edwin Davey, Guy's Hospital; Edward Green, Guy's Hospital; Baker Greenwell, Queen's terrace, St John's wood; Henry Thomas Lanchester, St Bartholomew's Hospital; John Tanner, Guy's Hospital; Joseph Todd, Birmingham.

Royal College of Surgeons.—The Museum and Library of this Institution will be closed during the month of September.

University of London.—At a meeting of Convocation, held at Burlington House on the 8th inst., for the purpose of nominating three persons out of whom the Crown is to select one to fill up a vacancy in the Senate, the following gentlemen were returned:—Mr George Jessel, M.A.; George Johnson, M.D.; and the Rev. Albert Crick, M.A. Their names are arranged according to their places on the poll.

St Thomas's Hospital.—The Rev. Ottywell Robinson, M.A., of Trinity College, Cambridge, Curate of St Mary Magdalene Church, Bermondsey, has been appointed an Assistant-Hospitaller of St Thomas's Hospital, Southwark.

Westminster Hospital.—The Governors of the Westminster Hospital have determined upon erecting a new post-mortem theatre, and making certain alterations in the buildings occupied by the anatomical department of the medical school, with the view of affording better accommodation to the increasing number of pupils of this rising institution. We hear that these improvements are already in hand, and will be completed by the winter session.

Epizootics in Russia.—The Russian papers state that a contagious disease has just broken out in the neighbourhood of St Petersburgh, called Pestis Syberiæ, or Carbunculus. It principally attacks domestic animals.

Marriages in Paris: Relative Ages of the Brides.—Out of 1000 marriages, it was found, in lately consulting the official register, that 32 women were from 15 to 16 years old; 100, from 16 to 17; 219, from 18 to 19; 233, from 20 to 21; 165, from 22 to 23; 103, from 24 to 25; 60, from 26 to 27; 45, from 28 to 29; 18, from 30 to 31; 14, from 32 to 33; 8, from 34 to 35; 2, from 36 to 37; and 1, from 38 to 39.

Mortality in Government Emigration.—The mortality on the whole emigration conducted by the Emigration Commissioners during the year 1859 amounted to 104 out of 10,581, equal to ·98 per cent. This satisfactory result is due, the Commissioners say, in great measure, to the reduction which they constantly keep in view in the number of young children on board their ships, and also to the experience and ability of the surgeons whom they are now able to retain in their service. In the seven years that have elapsed since the 1st of January, 1853, the mortality in 524 emigrant ships sent out by the Commissioners, carrying 172,233 souls, has amounted to only 2266, equal to 1·31 per cent. Of the 52 surgeons despatched to Australia, the Cape, and the East Indies, in their ships last year, 2 only were untried men: of the remaining 50, 3 had made one previous voyage; 3 had made two previous voyages; 10, three; 13, four; 8 five; 7, six; 3, seven; 1, eight; 1, nine; and 1, eleven.

Lay Medical Missionary to Africa.—The Committee of the Church Missionary Society have accepted as a lay medical missionary to the Yoruba Mission in Africa, Dr Arthur Aylett Harrison (B.A. 1853, Trinity College, Cambridge, 24th Wrangler and 1st Class Natural Science Tripos). Dr Harrison was previously educated at Rugby, and has, subsequently to his first degree, after visiting Natal, been pursuing the study of medicine in St Bartholomew's Hospital.

MM. Martin Magron and Buisson have made a very extensive experimental investigation into the comparative action of strychnia and woorara on the central nervous system, and the results of their experiments lead them to the conclusion that woorara acts on the motor nerves in the same way as strychnia; and consequently, that, in this respect, there is no antagonistic action, such as it has been stated exists between strychnia and woorara.

Criminal Lunatics.—An Act has just been passed to amend the Act regulating the Queen's Prison. Prisoners sent to Bethlehem Hospital under the former Act may now be removed, and be dealt with as if they were persons of sound mind. All lunatics removed to places from Bethlehem Hospital are to be under the provisions of the Lunacy Acts.

Increase of Population in the Second Quarter of 1860.—The Registrar-General says:—"In the 91 days of the quarter the births exceeded the deaths by 63,036. This excess represents the natural increase of the population in that period: the increase aided by ingress from Scotland, Ireland, and more distant parts, is more considerable; and at the present time it is probably very near the truth to state that England and Wales contain a population of twenty millions. The emigration of the last quarter consisted of 48,626 persons, who sailed from ports in the United Kingdom at which there are Government emigration officers. By distributing 8260, who are not distinguished as regards the country of their birth, proportionally over the rest who are thus distinguished, it appears that 9437 were English, 3461 Scotch, 33,438 Irish, and 2290 were foreigners. The United States was the destination of three-fourths of the whole number. Of the English emigrants, 5945 chose the United States, 2792 the Australian Colonies. Although in the emigration to America the Irish were five times as numerous as the English, a considerably less number of the former, as compared with the latter, went to Australia; while as regards persons of Scotch origin, it is remarkable that nearly as many went to the North American Colonies as to the United States, and more than twice as many went to Australia as to either of those parts of America. National character is in part the cause of these differences; but they are chiefly to be referred to the better or worse condition in life of the emigrants."

Report of the Select Committee on Lunatics.—The Report of the Select Committee appointed to inquire into the operation of the Acts of Parliament and regulations for the care and treatment of lunatics and their property, has just been published. The number of lunatics is on the increase. Taking the figures as they stand, it appears, that out of 600 people in England and Wales, one at least is incapable of managing himself and his affairs. Evidence shows that public asylums are so carefully attended to, that but little alteration is required in the law; the chief evil is the detention of a large number of pauper lunatics in workhouses. The Committee are of opinion that no person should be detained in a workhouse respecting whose sanity a doubt exists without a

Medical certificate, renewable quarterly, stating that the patient is a proper patient to be kept in the workhouse; that there should, if possible, be distinct wards for such patients, with distinct attendance; that the guardians of the union should specially visit such patients once in each quarter, and make a special entry on each such visit of their state and condition; that the commissioners should also visit them at least once in each year, and that the same power of removing any patient to an asylum should be given to the commissioners as that which the justices now have. Private asylums are considered under various heads. The Committee think that some houses, both in the metropolis and in the country, are not well suited to the purpose, and they think it would be advisable that, except in cases to be specially allowed by the visitors or commissioners, the proprietor, or, in case of joint ownership, one of the proprietors, should, as regards future licences, be required by law to reside on the spot. Under the second head, namely, the circumstances under which the patient may be placed under restraint, and the safeguards provided for the propriety of his confinement, they observe that the Medical certificate should be clear in its statement, and accurately framed. If such certificates were verified before a magistrate, it would operate as a check on too hasty a conclusion. Secondly, the Committee recommend that the certificate authorising the detention should be limited in the first instance to three months. It is now granted for an indefinite period. Thirdly, they recommend that the order for receiving the patient into the asylum should not be effective unless the applicant had himself seen the patient within three months of his signing the order. Fourthly, that a copy of the order and Medical certificates should be sent to the commissioners within twenty-four hours; and fifthly, that the patient should, as soon as possible, be visited by the commissioners, or by some persons acting directly under their authority. The next subject considered by the Committee is the treatment of the patient while in the asylum. The Committee think the late recommendation of the commissioners, that it should be made compulsory upon the friends of all private patients to see them periodically, deserves consideration. The *primâ facie* right both of receiving visits and of corresponding should, it is remarked, be secured to the patients, and should never be refused by the authorities, except on specified grounds. A power might with advantage be given to the commissioners and visitors of ordering the temporary discharge upon trial of a patient in a private asylum. It would be an improvement in the law if the notice of recovery of patients, which is sent to the commissioners or visitors after fourteen days' interval, were required to be sent simultaneously with the notice of recovery which is sent to the relations. On the advantages and disadvantages of confining patients in single houses other than their own, there is considerable conflict of opinion. In one thing, however, all the witnesses are agreed, that this class of patients ought to be brought under supervision of the commissioners, and the Committee think it should be made penal for any Medical man to receive any such patient without apprising the commissioners of it. As respects criminal lunatics, the measures which have been recently taken, and the State Asylum which is being erected at Broadmoor, will, the Committee think, ensure better classification and supervision. The commissioners may advantageously be required to visit this State Asylum, but the discretionary power of partially or entirely restoring a patient to liberty should be vested in the Secretary of State for the Home Department. The foregoing recommendations would probably require some alteration in the law as regards the commission; but, as the commissioners are of opinion that they could discharge the increased duties without any permanent addition either to their number or to their staff, the Committee abstain from any recommendation on the subject.—'Medical Times and Gazette.'

The Colney Hatch Case.—The following Medical evidence in this case will be read with interest:—Mr James Luke, Vice-President of the Royal College of Surgeons, Senior Surgeon of the London Hospital, and Surgeon to St Luke's Hospital for Lunatics, deposed: I have had considerable experience as a Surgeon, particularly with reference to the treatment of lunatics. I see all the patients as admitted to St Luke's. I have heard the evidence in this case, especially the Medical evidence with regard to the post-mortem examination. In my opinion the deceased man Swift died from the general injuries described, which, in my judgment, must have been inflicted at one and the same time. I should think that death followed speedily on those injuries. I believe it to be impossible that a person who had received such injuries could walk about in apparently good health, his constitution exhibiting no derangement, and his pulse giving no indication that he had been injured. The fact of the person injured being a lunatic would not make any material difference. The injuries might be produced by external pressure without producing any external marks of violence. I do not think the injuries could have been inflicted on the previous Wednesday. There is no statement in the Medical evidence of inflammation having occurred, which I should have expected had the injury been inflicted on the Wednesday. Had there been inflammation, the pulse would have been affected. The respiration also would have been extremely difficult—that is, supposing the patient could so long have survived such injuries. Cross-examined: I do not judge solely from the absence of evidence of inflammation in forming my opinion that the injuries could not have been received on Wednesday, but that is one of my reasons. A man might have his sternum and eleven ribs broken without any external ecchymosis. That might be, though the injury was done by kicks or blows, if he had his clothes on. I do not think that blows with the fist alone could have done all this mischief. I differ from the other Medical witnesses in saying that these injuries must necessarily have been accompanied with ecchymosis, and that the injuries might have been inflicted on Wednesday. A man with one or two ribs broken might go on a day or two without exhibiting much inconvenience, but not without any. His being a lunatic would make no material difference. I differ from Dr Tucker in thinking that it would. I have known cases where lunatics have injured themselves and have made no complaint. Among lunatics there are occasional instances of insensibility to pain, but in such cases there are other symptoms. There are other symptoms in this case. My impression is, that the fractured ribs and sternum would have caused death immediately. Maniacs sometimes hurt themselves and do not complain. Mr Lewis: If the ribs had been fractured on the Wednesday, would that have caused death on the Saturday? Witness: I think it would have caused death at once, and he certainly would not have lived till Saturday without exhibiting very distressing symptoms, which could not have been masked.—Mr Richard Partridge, one of the Council of the Royal College of Surgeons, and Professor of Anatomy at King's College, confirmed the evidence of Mr Luke. He knew from his own experience that injuries precisely similar to those described might be produced without the slightest external mark. Cross-examined: It is impossible that a man could have received these injuries on the Wednesday without exhibiting signs of them until Saturday. Re-examined: I have no doubt that all the internal injuries—the fracture of the ribs and sternum, and the rupture of the loin—were caused at one and the same time. All might be produced by a man kneeling on the body of the deceased. To Mr Lewis: Those injuries might be produced by a man falling from a height, but certainly not by his falling in a fit while in a room.

Routine.—Mr T. Duncombe lately moved for a copy of all instructions sent by the Privy Council Office or Poor-law Board to Boards of Guardians authorising expenditure on prosecutions of persons for refusing or neglecting to have their children vaccinated, with a number of other particulars respecting vaccination. The return was ordered, but the proper authorities answered that no such instructions had been issued, and there were no means of supplying the other information asked for. As the return, therefore, was useless, it might have been supposed that nothing further would be done with it; but the House of Commons sent it through the usual course and ordered it to be printed, and several hundred copies have just been printed accordingly. Twenty-eight columns are drawn out in solemn array, each headed with a description of the information it was to contain, but all left blank; and then at the foot is a statement that there is nothing to state. Every compositor, printer's reader, and pressman concerned might as well have been at crankwork.

Phosphorus in Plants.—M. B. Corenwinder read lately before the French Academy of Sciences a *résumé* of his studies on this subject. Young plants give ashes rich in phosphoric acid; but after maturity the grain, or fruit, stalks, and leaves contain but a small proportion. Phosphoric acid in plants is found in close combination with nitrogenous matters. The organs of the plant destitute of nitrogen and not required for its alimentation are also destitute of phosphates; but the pollen of flowers and the spores of cryptogamia contain a considerable portion of phosphoric acid. Marine plants growing on rocks also contain much phosphate.

Statistics of Amputations.—A fearful instance of the mischief arising from operations and bad hospital atmosphere is related of the result of the "pure" surgery of the Constantinople Hospitals from the period of the battle of the Alma to the end of the campaign. All amputations at or near the hip-joint died at once; whereas those exactly similar cases sent away and operated on under better hospital conditions by the French at Marseilles or in Paris did very well. Nearly all amputations engaging large bones, even fractures of such bones, were rapidly followed by pyæmia. Of 490 amputations of all kinds—several of them of the upper extremity, which *ought* never to die—192 terminated fatally, and 32 out of 49 disarticulations exhibited a like issue; nor is the general result of the treatment under the malignant influence of the hospital atmosphere of the French hospitals anything better. Their total number of amputations was 639, of which 419 were primary and 220 secondary; the primary of all operations (but that at the hip-joint, which seems to be an exception to the otherwise general rule) furnishing more than one-half cures—the secondary operations (whatever Mr Skey may urge to the contrary), being by far the worst cases, yielding, from their long continuance in hospital, 73 cures and 147 deaths.

APPOINTMENTS FOR THE WEEK.

Wednesday, August 22.

Operations at Middlesex Hospital, 1 p.m.; St Mary's Hospital, 1 p.m.; University College Hospital, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.

Thursday, August 23.

Operations at St George's Hospital, 1 p.m.; Central London Ophthalmic Hospital, 1 p.m.; London Hospital, 1½ p.m.; Great Northern Hospital, King's Cross, 2 p.m.

London Home.—2 p.m.

Friday, August 24.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, August 25.

Operations at St Thomas's Hospital, 1 p.m.; St Bartholomew's Hospital, 1½ p.m.; King's College Hospital, 1½ p.m.; Charing Cross Hospital, 2 p.m.

Monday, August 27.

Operations at the Royal Free Hospital, 2 p.m. Metropolitan Free Hospital, 2 p.m.

Tuesday, August 28.

Operations at Guy's Hospital, 1½ p.m.; Westminster Hospital, 2 p.m.

BOOKS RECEIVED FOR REVIEW.

On the Invention of Stereoscopic Glasses for Single Pictures. By T. Wharton Jones, F.R.S. London: John Churchill.

Proceedings of the Second Annual Meeting of the London Surgical Home.

NOTICES TO CORRESPONDENTS.

A Subscriber from the Beginning should communicate with the Editors of the 'Directories.'

Dr Pierson.—Communication with enclosure received.

Omega.—The New Sydenham Society is prospering. You should apply to Mr Hutchinson, the secretary. No entrance-fee is required.

Medicus (Bridport).—1st. No.—2nd. No.

Dr H. C.—We cannot see the probable advantage of the course you suggest. You had better wait to see what the Committee of the British Medical Association will recommend. Unity, and not division, should be the end arrived at.

Mr Fleming.—Received.

Mr Simpson.—Yes; in October.

A Union Surgeon.—Note received. We cannot give you a satisfactory reply.

Dr Mackenzie is thanked for his intimation.

An L.S.A.—Not at present.

W. W.—1st. You would be eligible for examination after due attendance upon the required course of study.—2nd. Glasgow, if convenient to you, is a good school.

Metron wishes to know if a General Practitioner, not conducting a retail business, is liable to have

his weights and measures inspected by the ordinary officer? We are not aware that there is any exemption in favour of Medical Practitioners; but as it is a power that may be exercised offensively, perhaps some of our readers may be able to give more specific information.

MEDICUS reminds us that the principal writers in the Medical journals are engaged in denouncing Special Hospitals and Specialists. We are aware of the fact in two or three instances; or at least that these gentlemen are trying to become such, and are looking out for a chance. It would not surprise us to be told that the most rabid articles have been written by a tolerably well-known Specialist. Our correspondent ought to know that it is too common for public writers to express sentiments not so much in accordance with their own practice, as in accordance with the supposed opinion of the majority whom they address. This practice has led to the inconsistency and humbug of modern journalism.

AN OLD SUBSCRIBER.—1st. The question is an open one; but it seems to us that the College must obtain a new Charter beforehand.—2nd. We do not know; you should write to the War Office.—3rd. We are unable to inform you of the amount of salary paid to Inspectors of Mines, or the amount of their travelling expenses.

AN ADMIRER.—Who is "Winslow?" Our admirer speaks in parables; and, unfortunately, we are not quick at unravelling mysteries or jokes. Our correspondent, if he be not insane, evidently means to be sarcastic—either upon us, or the person he calls "Winslow;" but we cannot comprehend the enigma. We hope "Admirer" will explain his own joke; we can see nothing in it but its spitefulness.

CHLORODYNE.

To the Editor of the Medical Circular.

SIR,—In justice to myself and the Medical Profession at large, I beg you will insert these few lines to correct an erroneous impression. Your observations in last week's journal are suggestive respecting the composition of Chlorodyne.

The formula published as Dr Ogden's Analysis purporting to be Chlorodyne is quite incorrect; synthesis will readily prove this. Not only does it differ in appearance and taste, but its action on the system will be found quite dissimilar.

Yours obediently,
J. T. DAVENPORT.

33 Great Russell street,
Bloomsbury, August 18th.

MR MILTON'S continuation of his papers has been received, and shall have early insertion.

DR PARK (Broughton Ferry).—Received.

DR ALDRIDGE'S communication has been received, but arrived too late for consideration this week.

A SUBSCRIBER.—The Degree would not be recognised.

MR WARRY.—Note received.

St Bartholomew's Hospital

and MEDICAL COLLEGE.—The WINTER SESSION will commence on OCTOBER 1st, with an INTRODUCTORY ADDRESS by Mr SAVORY, at Eight o'clock p.m.

LECTURES.

Medicine—Dr Baly and Dr Kirkes.
Surgery—Mr Lawrence.
Descriptive Anatomy—Mr Skey and Mr Holden.
Physiology and General Anatomy—Mr Savory.
Chemistry—Dr Frankland.
Superintendence of Dissections—Mr Callender and Mr Smith.

SUMMER SESSION, 1861, commencing MAY 1st.

Materia Medica—Dr F. Farre.
Botany*—
Forensic Medicine—Dr Black.
Midwifery, &c.—Dr West.
Comparative Anatomy*—
Practical Chemistry—Dr Frankland and Mr Attfield.

* These Lectureships on Botany and Comparative Anatomy have been recently vacated, but the names of the Lecturers will be shortly announced.

HOSPITAL PRACTICE.—The Hospital contains 650 beds, and relief is afforded to more than 90,000 Patients annually. The In-Patients are visited daily by the Physicians and Surgeons, and Clinical Lectures are delivered—On the Medical Cases by Dr Burrows, Dr Farre, and Dr Black; on the Surgical Cases, by Mr Lawrence, Mr Stanley, Mr Lloyd, and Mr Skey. The Out-Patients are attended daily by the Assistant-Physicians and Assistant-Surgeons.

COLLEGIATE ESTABLISHMENT.—Students can reside within the Hospital walls, subject to the rules of the Collegiate system, established under the Direction of the Treasurer and a Committee of Governors of the Hospital. Some of the Teachers and other Gentlemen connected with the Hospital also receive Students to reside with them.

SCHOLARSHIPS, PRIZES, ETC.—At the end of the Winter Session, Examination will be held for Two Scholarships of the value of £45, for the year. The Examination for Prizes and Certificates of Merit will take place at the end of the Winter and Summer Sessions.

Further information may be obtained from Mr Paget, Dr Kirkes, Mr Holden, or any of the Medical or Surgical Officers or Lecturers; or at the Anatomical Museum or Library.

J. ALDERMAN,

PATENTEE, INVENTOR, AND MANUFACTURER

OF THE

GRADUATING SPINAL FRACTURE AND GENERAL INVALID COUCHES, CHAIRS, CARRIAGES, AND EVERY OTHER DESCRIPTION OF ARTICLE REQUIRED BY INVALIDS.

MANUFACTORY, 8 DENMARK STREET; SHOW ROOMS, 16 SOHO SQUARE.

St Thomas's Medical Session.

A General INTRODUCTORY ADDRESS will be delivered by R. D. ORAINGER, Esq., F.R.S., on MONDAY, 1st OCTOBER, 1860, at Eight o'clock p.m.

The DISTRIBUTION of PRIZES will take place early in the Session.

Gentlemen have the option of paying £40 for the first year, a similar sum for the second, and £10 for each succeeding year; or £90 at one payment, as perpetual.

A rumour having been current that this Hospital will shortly be removed to another site, it is thought desirable to contradict such report.

PRIZES AND APPOINTMENTS FOR 1860-61.

Voluntary Matriculation Examinations are held early in October, and Prizes are given in each of the three following divisions:

1st. In Mathematics, Classics, and Ancient History. The President's Prize of 20 Guineas.

2nd. In Physics and Natural History. A College Prize of £20.

3rd. In Modern Languages and Modern History. A College Prize of £20.

THE TITE SCHOLARSHIP, founded by W. TITE, Esq., M.P., F.R.S., the proceeds of £1,000 Consols, tenable for three years.

To the Three most distinguished Pupils for General Proficiency in each year, the following Prizes are awarded:

FIRST YEAR'S STUDENTS.

1st. The Treasurer's Prize of 30 Guineas. 2nd. A College Prize of £20. 3rd. A College Prize of £10.

SECOND YEAR'S STUDENTS.

1st. A College Prize of £30. 2nd. A College Prize of £20. 3rd. A College Prize of £10.

The Dressers and the Clinical Clerks are awarded to merit, after examination.

THIRD YEAR'S STUDENTS.

1st. A College Prize of £30. 2nd. A College Prize of £20. 3rd. A College Prize of £10.

MR GEO. VAUGHAN'S Cheselden Medal. The Treasurer's Gold Medal.

MR NEWMAN SMITH'S Prize of £5 for the best Essay on "Neuralgia."

The Two House Surgeons, the Resident Accoucheurs, and the Dressers are periodically selected, and are provided with Rooms and Commons in the Hospital, free of expense.

Two Hospital Registrars at an Annual Salary of £40 each, or one at £80.

Students of each year are classed according to their respective total merits in the examinations, and all of the First Class receive Certificates of Honor.

MEDICAL OFFICERS.

Dr Roots, Consulting Physician; Mr Green, Consulting Surgeon; Dr Barker, Dr J. Risdon Bennett, Dr Goolden, Dr Peacock, Dr Bristowe, Dr Brinton, Mr South, Mr Mackmurdo, Mr Solly, Mr Le Gros Clark, Mr Simon, Dr Waller, Dr Clapton, Mr Sydney Jones, Mr Whitfield.

Clinical Instruction is given at stated times by the Medical and Surgical Officers; and Special Medical Clinical Lectures, by Dr Barker. Ophthalmic Surgery, Mr Mackmurdo; Midwifery, Dr Waller and Mr Gervis; Dental Surgery, Mr Elliott; Medical Tutors, Mr Allingham and Mr Gervis.

Medicine—Dr Peacock. Surgery, Mr Le Gros Clark. Physiology — Dr Brinton. Descriptive Anatomy — Mr Sydney Jones. Anatomy in the Dissecting Room—Mr Rainey. Assistant Demonstrator—Mr J. Croft. Chemistry and Practical Chemistry—Dr Albert J. Bernays. Midwifery — Dr Waller. Practical Midwifery — Mr Gervis. General Pathology — Mr Simon. Botany — Dr Clapton. Comparative Anatomy—Mr W. M. Ord. Materia Medica—Dr Bristowe. Forensic Medicine — Dr Stone. Public Health—Dr Headlam Greenhow. Demonstrations Morbid Anatomy — Dr Edmund Montgomery. Microscopical Anatomy—Mr Rainey.

Students can reside with some of the Officers close to the Hospital.

The Committee of the "Nightingale Fund" has arranged with the authorities of St Thomas's, for educating women as Hospital Nurses, who, on the satisfactory completion of one year's training, will be considered eligible to receive appointments as Nurses in the Metropolitan or Provincial Hospitals.

Applications can be made prior to next Midsummer to Mrs W. W. Wardroper, at St Thomas's Hospital.

The Patients are admitted daily at Half-past Eleven a.m., and the Out-Patients seen at Half-past Twelve daily.

To enter, or obtain Prospectuses, the Conditions of the Tite Scholarship, and further information, apply to Mr WHITFIELD, Medical Secretary, resident at the Hospital.

St Mary's Hospital Medical

SCHOOL.—The WINTER SESSION will commence on MONDAY, OCTOBER 1st, at Eight o'clock p.m., with an INTRODUCTORY ADDRESS by Dr TYLER SMITH, after which a Conversazione will be held in the Museum.

It is a distinctive characteristic of St Mary's Hospital that its Medical Appointments are conferred upon the Pupils without additional fee. Three Resident Medical Officers are appointed for Twelve Months, and one, the Obstetric Officer, for Six Months, all of whom board free of every expense in the Hospital. The money-value of these five appointments far exceeds as many Scholarships of £50 each. Four non-Resident Medical Officers are also selected from the best-qualified Students.

Physicians—Dr Alderson, Dr Chambers, Dr Sibson, Dr Handfield Jones, Dr Sieveking, and Dr Markham.
Surgeons—Mr Coulson, Mr Lane, Mr Ure, Mr Spencer Smith, Mr Walton, and Mr James Lane.
Physician-Accoucheur—Dr Tyler Smith.
Ophthalmic Surgeon—Mr White Cooper.
Aural Surgeon—Mr Toynbee.
Surgeon-Dentist—Mr Sercombe.

LECTURES.—Clinical Medicine — Dr Alderson, Dr Chambers, and Dr Sibson. Clinical Surgery — Mr Coulson, Mr Lane, and Mr Ure. Medicine—Dr Chambers and Dr Sibson. Surgery — Mr Coulson and Mr Spencer Smith. Physiology and Morbid Anatomy—Dr Markham and Mr James Lane. Anatomy—Mr James Lane and Mr Gascoyen. Operations on the Dead Body—Mr Walton. Dissections — Mr Gascoyen and Mr Davy. Chemistry and Practical Chemistry—Mr Field. Midwifery—Dr Tyler Smith and Dr Grailly Hewitt. Materia Medica—Dr Sieveking. Botany—Dr Dresser. Medical Jurisprudence—Dr Sanderson. Ophthalmic Surgery—Mr White Cooper. Aural Surgery—Mr Toynbee. Dental Surgery—Mr Sercombe. Comparative Anatomy—Dr Grailly Hewitt. Natural Philosophy—Mr Smalley.

The In-Patients are visited daily by the Medical Officers, and the Out-Patients are also attended daily by the Physicians and Surgeons in charge of them. During the past year relief was afforded to 1549 In-Patients and to 13,727 Out-Patients. A Maternity Department is also attached to the Hospital.

Students are required to perform the duties of Clinical Clerks and Dressers, in each Session, during the last two years of their curriculum.

SCHOLARSHIP, PRIZES, ETC.—In addition to the Medical Appointments mentioned above, a Scholarship in Anatomy of the annual value of £25 is offered to the Students. Examinations for Prizes will take place at the end of each Session.

The Fee for the Hospital Practice and Lectures required by the College of Surgeons and Society of Apothecaries is £89 5s., which may be paid by instalments.

Further information may be obtained on application to the Dean of the School, who will also furnish the names of Gentlemen in Practice near the Hospital willing to receive Pupils to reside with them.

GEO. C. GASCOYEN, Dean of the School.
St Mary's Hospital, August, 1860.

Huxley's Spiral Abdominal

BELT, is constructed on a principle which secures the required support, without being liable to displacement, and is invaluable, when properly constructed, in cases of Pregnancy, Obesity, Ovarian Dropsy, &c. When required, it is fitted with Air-pads for Umbilical, Inguinal, and Femoral Hernia, and Band with Air-pad for Prolapsus Uteri and Prolapsus Ani. These goods, in addition to Stockings, Thigh-pieces, Knee-caps, &c., supplied 30 per cent. lower than the prices hitherto charged, every article being of the very best quality.—Measures required: circumference at a, b, c; depth, from a to c.—Priced and Illustrated Catalogues on application to

E. HUXLEY,
12 Old Cavendish street, Oxford street, W.

Notice of Removal.—W. F.

DURROCH, Surgical Instrument Maker to the Royal Navy, Greenwich Hospital, &c. &c., respectfully informs the Profession that, in consequence of his present premises, No. 2 New street, coming down, he is removing to more extensive premises, No. 28 ST THOMAS STREET EAST, where he will continue to manufacture Surgical Instruments of every description upon the most liberal terms.

Mr YEARSLEY'S WORKS OF THE EAR AND THROAT.

DISEASES OF THE EAR.

Fifth Edition, price 2s. 6d., by post 2s. 8d.

Deafness Practically Illustrated, as to its Nature, Causes, and Treatment.

"A careful perusal has convinced us that the author is correct in his views; his experience has been ample, and his powers of observation and research have been by no means inferior to his opportunities."—'Medical Gazette.'

"A thorough acquaintance with the facts and views which it contains must be regarded as essential to the Medical Practitioner."—'The Lancet.'

"Contains much practical information."—'Medical Times.'

"Well deserving attention."—'British and Foreign Medico-Chirurgical Review.'

"The author's observations will be read with advantage, and will afford many useful hints for the detection and management of disease."—'Provincial Medical Journal.'

DISEASES OF THE THROAT.

Also just published, price 5s., by post 5s. 4d., the Seventh Edition, with new Plates,

On Throat Ailments, more especially the ENLARGED TONSIL and Elongated Uvula, in connection with Defects of Voice, Speech, Hearing, Deglutition, Respiration, Susceptibility to Cold and Sore Throat, Cough, Nasal Obstruction, and the Imperfect Development of Health, Strength, and Growth in Young Persons.

"Mr. Yearsley's great experience in diseases of the throat and ear, and in affections of the voice and speech, entitles all he says to much attention and consideration."—'The Times.'

THROAT-DEAFNESS.

Price 1s., by post 1s. 1d.

On Throat Deafness, and the PATHOLOGICAL CONNECTIONS of the THROAT, NOSE, and EAR. Reprinted from the Author's larger work, 'Deafness Practically Illustrated.'

On the Artificial Tympanum. A New Mode of Treating Deafness, when attended by Partial or Entire Loss of the Membrana Tympani, associated or not with Discharge from the Ear.

Reprinted from the 'Medical Circular,' price 1s., by post 1s. 1d. Second Edition.

On a New Method of Treating OTORRHŒA.

"The sensation of comfort, and the removal at once of all offensive fœtor which is so distressing to the patient are not the only advantages gained by this novel mode of treatment."—Preface.

London: John Churchill, 11 New Burlington street.

TO SURGEONS, DENTISTS, &c.

The Best House in London for SECOND-HAND INSTRUMENTS is Mr WM. LAWLEY'S, Lombard House, 78 Farringdon street, City.

Established upwards of a century.

A first-class full SURGEON'S ARMY CASE by 'WEISS"—(Quite New).

N.B. The largest stock of Second-hand Dissecting Cases in London. Also, A great variety of New and Second-hand Army and Navy Regulation Cases.

Instruments Bought, Sold, or Exchanged.

Wines, guaranteed Pure and Genuine, at per Dozen, including bottles: Fine old Port, 26s.; superior old Sherry, 24s.; superior old Claret, 26s.; finest old Sicilian Sherry, 24s.; superior Champagne, 32s.; fine old Pale Cognac Brandy, 44s. Samples forwarded, free on application.

T. W. REILLY,

33 Finsbury place North, Finsbury square, London, E.C.

Post-office Orders with Country Orders.

Notice—Behenna and Co. ACCOUNTANTS, conduct all business entrusted to them, with secrecy, economy, and despatch. Accounts prepared in Bankruptcy and Insolvency. Arrangements made with Creditors. Tradesmen's Books regularly kept. Partnerships and Loans negotiated. Offices, 11 Beaufort buildings, Strand London W.C. Hours from 10 till 4.

New Remedies by Savory AND MOORE.

HYPOPHOSPHITE OF QUININE,

SYRUP OF HYPOPHOSPHITE OF QUININE AND IRON,

which have been employed with highly satisfactory result in debility and low vitality.

LIQUOR NASTURTII (Fluid Extract of Watercress) of great therapeutic value in the various forms of scorbutic affections.

CARBONATE of LITHIA; Hypophosphite of Lime, Soda, and Ammonia; Syrups of Phosphate of Iron, Lime, Manganese, &c.

GENUINE MEDICATED COD-LIVER OILS (introduced by Messrs Savory and Moore), are also prepared in the Laboratory, 143 New Bond street, London.

THE NEW EYE DOUCHE,

invented by SAVORY and MOORE, has elicited the approbation of the most eminent Oculists. Vide 'The Lancet' of March 31st.

E. BURTON'S ACHROMATIC MICROSCOPES

Cannot be surpassed at the price. An excellent (Student's) Microscope, with set of Achromatics, Pliers, and Condenser, in Cabinet, £3 3s.

Microscopes with powers. Live and Water Boxes, 6 objects, &c., packed in polished mahogany case, at 12s. 6d. 21s., 31s. 6d., 50s.

Manufactory, 47 Church street, Minories, London, E.

An Illustrated Catalogue upon application, or receipt of two stamps.

Paper and Envelopes.

A SAVING OF FULL 6s. IN THE POUND.

Cream Laid Note, 2s., 3s., and 4s. per ream.

Large Blue Wove ditto, 3s. 6d. and 4s. 6d. per ream.

SUPER THICK CREAM LAID ENVELOPES, 6d. per 100.

Manuscript Paper, 4s. 6d., and Foolscap, 6s. 6d. per ream.

Bordered Note, Five Quires for 1s.

STRAW Paper, 2s. 6d. per ream.

NO CHARGE for Plain Stamping. Dies engraved from 2s. 6d.

White and Blue Demys, and other Wrapping Papers, at a small commission on the mill prices.

Price List post free. SAMPLE packet for six stamps.

CARRIAGE PAID to the country on orders over 20s.

PARTRIDGE and COZENS, Manufacturing Stationers, No. 1 Chancery lane, and 192 Fleet street, E.C.

RUPTURES. BY ROYAL LETTERS PATENT.

White's Moc-main Lever TRUSS is allowed by upwards of 200 Medical Gentlemen to be the most effective invention in the curative treatment of HERNIA. The use of a steel spring, so often hurtful in its effects, is here avoided: a soft bandage being worn round the body, while the requisite resisting power is supplied by the 'MOC-MAIN PAD and PATENT LEVER, fitting with so much ease and closeness that it cannot be detected, and may be worn during sleep. A descriptive circular may be had, and the Truss (which cannot fail to fit) forwarded by post, on the circumference of the body two inches below the hips being sent to the Manufacturer,

JOHN WHITE, 228 Piccadilly, London.

Price of a Single Truss, 16s., 21s., 26s. 6d. and 31s. 6d.—Postage, 1s.

Price of a Double Truss, 31s. 6d., 42s. and 52s. 6d.—Postage, 1s. 8d.

Price of an Umbilical Truss, 42s., and 52s. 6d.

Postage, 1s. 10d.

Elastic Stockings for Varicose Veins, and all cases of Weakness and Swelling of the Legs, Sprains, &c. They are porous, light in texture, and inexpensive, and are drawn on like an ordinary Stocking. Price 3s 6d. 7s. 6d., 10s., and 16s. each. Postage, 6d.

JOHN WHITE, MANUFACTURER,

228 Piccadilly, London.

Millikin, late Bigg and Millikin, Surgical Instrument Maker and Anatomical Machinist to Guy's and St Thomas's Hospital, No. 9 St Thomas's street Southwark S.E.

Important to Surgeons.—The old-established and well-known Business of JOHN MILLIKIN, now MILLIKIN and LAWLEY, 161 Strand, adjoining King's College. A change in the proprietorship offers to Surgeons the opportunity of purchasing any kind of Instrument from this well-manufactured stock, which cannot be surpassed in style, quality, or price.

Messrs MILLIKIN & LAWLEY beg to draw the attention of their friends and customers to the superior stock of Mathematical Instruments, their great variety of Cutlery, and the selection of first-class Microscopes, Opera and Race Glasses.

A great variety of Skeletons, Skulls, Hands, Feet, &c., of superior quality, at moderate charges.

Every description of Surgical Instruments made to order, with the utmost PRECISION and DESPATCH.

Surgical Instruments and Cutlery Repaired Daily.

S. W. Silver and Co.'s OUTFITTING WAREHOUSES, 66 and 67 Cornhill, E.C.—OUTFITS for Australia, India, and China, for Naval and Military Officers, Cadets, Midshipmen, and Civilians; clothing for gentlemen's home use—viz., Naval and Military uniforms and civilian dress of the best material and workmanship; shirts, hosiery, gloves, &c.; ladies' outfits; furniture for camp, barrack, cabin, and colonial use, embracing every variety of cabinet work, canteens, trunks, portmanteaus, &c., suited to all climates.

Manufactory, Silvertown (opposite H.M. Dockyards), Woolwich.

Medical Practitioners Supplied with ASSISTANTS, gratis, by MAIR and SONS, 34 Bedford street, Strand, who also DISPOSE of PRACTICES on moderate terms.

Fresh Air.—"McKinnell's PATENT VENTILATOR does that which is the great object in keeping buildings healthy. It rids them of the foul air, and provides for the free inlet of a fresh supply. It is simplicity itself—as, indeed, are most of the Mechanisms adapted to Natural Laws. It can be fitted with ease to carriages, ships, houses, coal-mines, schools, churches, &c. The system, too, is cheap."—'Medical Times,' July 7, p. 11.

JOHN McKINNELL, Patentee, 9 Gloucester terrace, Clarendon road, London, W. Descriptive Pamphlets sent on receipt of one stamp.

Pure Country Milk and CREAM.—Messrs EDMONDS and BAYNES, OXGATE FARM, WILLESDEN, have received the most flattering testimonials from several eminent Members of the Medical Profession in favour of the purity and freshness of their MILK and CREAM, which they undertake to supply Twice Daily to any part of the West-end. Orders received as above, or at the Office, 16 Marchmont street, Russell square; and at St Petersburgh place, Bayswater, W.

CREAM being now recommended as a substitute for COD-LIVER OIL, Messrs E. and B. beg to inform the Profession that they can supply it in any quantity with punctuality.—A prospectus free by post.

H. Silverlock's Medical Label Warehouse, Letter-Press, Copper-Plate, and Lithographic Printing Offices, Wardrobe terrace, Doctors' Commons, London, E.C.

H. Silverlock's stock of LABELS for DISPENSING purposes, having been recently revised and enlarged, now consists of upwards of 800 different kinds. Yellow and Green Labels for Drug Bottles, Drawers, &c., at per book or dozen; a Book, containing a selection in general use in Surgeries or Dispensaries, 10s. 6d.

Printed Catalogues of the above may be had, post free on application.

Printing of every description at moderate prices.

Bed Bugs, Green Fly, Red SPIDER, MILDEW.—GISHURST COMPOUND, patented for killing and keeping away these and other animal and plant pests. Names of eminent authorities who have given testimonials to its success are advertised in the 'Gardener's Chronicle,' 'Cottage Gardener,' and 'Field.' Sold in boxes at 1s., 3s., and 10s. 6d., with reports of trials and full instructions for use, by Chemists and Nurserymen. Wholesale by

PRICE'S PATENT CANDLE COMPANY, LIMITED.

ON THE TREATMENT OF GONORRHŒA WITHOUT SPECIFICS.

By J. L. MILTON, Esq., M.R.C.S.

(Continued from page 103.)

In six cases out of eight in which I collected the history, and had an opportunity of tracing them to their close, a complete though slow cure of the abscess took place: the gonorrhœa, however, proved more difficult to subdue than in any other cases. In the seventh, the patient, just as the abscess was a little improved, gave up the medicine in disgust, and soon returned with a larger and more painful swelling. This was also subdued by the use of the antimony; but though he was attended regularly, the urethra long felt hard and tight at the seat of the abscess, and a gleety discharge remained, which proved very intractable. On passing the bougie, the canal did not appear much narrowed; but it was somewhat twisted, and peculiarly hard and inelastic: there was also considerable dribbling after making water. More than a year after this I met him, when he informed me that he had had no return of the gleet, but the uneasy feeling of hardness was still there.

The eighth case was that of a gentleman in whom the abscess had been checked eighteen months previously by the heroic use of leeches, poultices, &c. Since that time the discharge had never diminished, and was now thick and yellow. He had taken large quantities of medicine, principally copaiba and cubebs, but without any result except that of increasing disgust for all physicking. For three or four months he tried blisters, aperients, and injections with unwearied perseverance, but with no effect. I wanted to cauterise the urethra and use bougies, but he said he had suffered so much that he could not bear the idea of instruments. At last he permitted me to introduce a gum-elastic bougie: on reaching the seat of the abscess, the urethra was found excessively tender and irregular. Three years subsequently he again consulted me for two confirmed and very tight strictures of the urethra, one of which was only an inch and a half from the orifice. He had for some time always carried a small bougie, which he occasionally passed a little way down. The discharge had never ceased; his health seemed quite broken down, and he presented a melancholy picture of a constitution, never very sound, now to all appearance ruined for want of resolution to undergo a mild operation. He still persisted in refusing to allow bougies to be used.

These cases, coupled with others which I could not watch so completely, led me to believe not only that perinæal abscess should be attacked with the utmost vigour, but also that the treatment ought to be continued till the hardness has entirely disappeared. Subsequent experience has enabled me to verify this opinion; and of late years I have always, so soon as the antimony had checked the inflammation, used the iodide of potass in combination with liquor potassæ, till some effect was produced. The perinæum should be blistered as often as the patient will allow it, and during the intervals blue ointment combined with camphor may be rubbed in every night. The bougie is also to be passed twice a week, so soon as the state of the urethra will permit.

On Abscess or Inflammation of the Prostate I need not dwell, as the case I have given in the section on "weakness" will exemplify the treatment better than description. It is one of the few complications, if not the sole one, in which leeches appear to be of service; in all other respects it may be treated the same as abscess in the perinæum, and the cure of the gonorrhœa may proceed without a check.

7.—*Gonorrhœal Rheumatism and Ophthalmia.*—Of all the varieties of complication, this is, I think, without exception the most formidable, and the least amenable to treatment. Whether a simultaneous affection of the eye and fibrous tissue depends upon a conjunction of two varieties of diathesis, or whether, when one alone appears, it owes its origin to a less developed form of the same disease, I must—though my own convictions lean rather in favour of the latter view—leave to be determined by more able pathologists than myself. I refrain from discussing subjects upon which I can throw no light.

The question, however, of whether these disorders are constitutional effects of suppressed gonorrhœa, appears to me of so much importance, that I wish to examine it a little more fully. Having been led to adopt views differing widely from those generally received, I offer them with diffidence.

I have in different papers (*a*) endeavoured to show that the organs of which the human frame is composed naturally divide themselves into four great classes: 1. Those of generative life; 2. Those of animal life; 3. Those of organic life; 4. Those of extinct life—as the thymus, thyroid gland, &c.: that maladies commencing in one class have little tendency to pass to another set of structures, although one class may sympathise with another; and that this sympathy, this slight tendency spoken of, are obedient to some law which has yet to be worked out.

Thus in gonorrhœa—an affection of the organs of generation—such structures as the eye and skin, fibrous tissues, &c., sometimes, though rarely, become involved; those of organic life, never; yet one or both may sympathise. When gonorrhœa first attacks a patient, the weariness, lumbar pains, &c., show a sympathy between the generative and the animal life. If subsequently ill-health (an affection of the organic life) ensue, it is chiefly from the prolonged action of medicines, and the mental irritation caused by the tedium of the disease. And if one of the structures of extinct life, as the prostate, becomes involved in the extension of the gonorrhœal inflammation, it is mechanically—it is by the sympathy of contiguity only; the distant organs of this class—the thymus gland, spleen, &c.—never suffer.

If these inductions be correct, the diseases attributed to suppressed gonorrhœa are simply due to the disturbance occasioned by gonorrhœa calling into play a latent tendency to disease. Indeed, there is no such thing as a suppressed or repelled gonorrhœa, especially here, where the discharge is almost always present. It may be temporarily kept in abeyance, as by cholera or fever; but what really suppresses, cures it. Moreover, I have frequently seen it where neither medicines nor injections had been used. So sudden is the outbreak of this terrible affliction, that the pain has sometimes begun within forty-eight hours after the outbreak of the discharge; and I have even known patients uncertain as to which began first. It may appear as late as three months after the discharge. I have seen it attack the hip, loins and great pectoral muscle, and Dr Elliotson has seen it fasten on the jaw, with great severity.

In respect to the treatment of gonorrhœal rheumatism, I can only copy at a distance that inculcated by the best practitioners of modern times—such as Mr Lawrence, Sir B. Brodie, &c. (*b*)—in their use of colchicum and purgatives; but, at the same time, I must candidly avow that with them alone we cannot meet the disease. Iodide of potassium is essential, and equally so is the free use of blistering. I have seen cases where the patients, after many months of suffering and lameness, began to improve so soon as these remedies were freely employed.

To my thinking, it is useless with adults to try anything less than half-drachm doses of colchicum wine; even drachm doses often fail. No fear need be felt about giving this quantity. I have prescribed twenty drops at a time to a child eleven years old, and seen the dose taken without any ill symptoms. Where blistering fails, I would at once resort to tartar-emetic ointment; and I have seen atropine in the same shape prove of great service.

The tenacity with which this rheumatic form of action continues in some persons is extraordinary. In the beginning of January, 1857, a young, healthy-looking man applied to me with chronic gonorrhœal rheumatism, which had incapacitated him for four successive winters from doing any work. It was principally seated in the sole of the foot, and the pain was so severe that he could not stand more than half an hour. If he attempted to exceed this time, a hot, burning pain attacked every part on which the weight of the body rested; and this soon became so severe as to compel him to lie down. Even when resting, the pain became so excessive towards night that he could not wear a boot. He had wandered about from one surgeon to another, till at last, from sheer poverty, he was obliged to enter a hospital, where he remained eight weeks. He came out as bad as he went in. This seemed a strange state of matters; however, the iodide of potassium and strong blisters to the feet relieved him so rapidly, that in five or six weeks he was able to do a little work. I learned from time to time that he was steadily improving, but I never knew whether he was cured, though I was informed by his landlady that he could get through a fair day's work.

In this case the pains began three days after the appearance of the gonorrhœa, and resisted three separate salivations, carried so far as to loosen the teeth. What else he had used, he could not tell; but I gathered from his account that galvanism, cramps to the feet, and mustard-poultices had been tried.

In another case, the patient could not carry his hand to the back of his neck, and was almost incapacitated from doing any work; yet the first blister so relieved the shoulder in which the pain was principally seated, that he informed me the ointment (employed after the blister) had "soupled" the joint. At the end of ten days he could place his hand on the back of his neck; and a second blister so far improved him, that, to my regret, he left off his treatment and went to sea again.

With regard to ophthalmia, it is on account of this rheumatic tendency, most necessary to distinguish that form in which the patient is attacked with ophthalmia and rheumatism, from that in which the gonorrhœal matter is conveyed to the eye, this being a much more rapidly destructive disorder. Mr Lawrence (*c*) observes that this so-called metastatis is peculiar to males; as to either arising from repulsion, the idea is simply absurd. The only application of any service is the nitrate of silver in solution, which I have never seen fail, if used early enough. Opium in large doses is of great value; and the treatment, to my thinking, should be essentially tonic. The horrors recorded by Wardrop, Lawrence, Adams, (*d*) is that at least half the victims to the destructive influence of antiphlogistic treatment lose their sight.

8.—*Bleeding* is the last of these complications. All those I have seen affected with it had suffered from disorder of the liver. The mildest injections produced bleeding from the urethra, and I was obliged in all cases to give them up until this tendency gave way, which it generally did in a little while under the use of aperients and tincture of steel. The gonorrhœa was very mild in these patients.

PART IV.—*Gleet and Inveterate Gonorrhœa.*—At first sight nothing seems easier to cure than a gleet; yet even slight complaints are more difficult to subdue, and the number of remedies suggested by authors only proves how often all their resources have failed.

Some authors—as Professor Graves, M. Ricord, Mr Whately, &c.—candidly confess that they have met with instances where the disease did not yield to any treatment; but, in general, writers are rather careful how they commit themselves to any very decided statements. The manner, however, in which the subject has been handled, leaves no doubt on the mind of the reader that the authors in question are quite familiar with those obstinate cases which go on for months, or even years, till at last the patient gets so thoroughly sick of medicines, that he makes up his mind to endure an evil he cannot remedy.

The following digest will, I think, comprise the pith of all the directions and suggestions by those authors I have consulted:—The specific remedies having failed, they may be tried combined or along with steel or cantharides; then the bougie is to be used, or the urethra may be cauterised: these failing, constitutional treatment is to be suggested, or change of air, sea-bathing, or the cold plunge bath, or perhaps an alterative course of mercury. Finally, we are told of cases where the *coup-de-grace* has been given to the rebellious disease by some strong remedy, warranted only by a desperate state—such as an injection of

(*a*) See one read before the Medical Society of London, Dec. 2nd, 1853.

(*b*) Langston Parker. 'Modern Treatment of Syphilitic Disease,' p. 69. Schmidt's 'Jahrbuch,' 37, 1843, pp. 43, 46.

(*c*) 'On Diseases of the Eye,' 1841, p. 280.

(*d*) 'Lancet,' 1852, vol. ii, p. 289.

brandy, a violent debauch, a drastic purgative, a seton, or a blister to the perinæum—so that the despairing reader has a method of getting out of the difficulty equally safe to himself and useless to the patient.

It is very safe to go into generalities, to offer simply collective experience, but it does not meet the difficulties of the subject. A surgeon who has an obstinate gleet to cure does not feel much wiser after reading over a list of remedies which would take two or three years to master thoroughly.

Now, when a case of gonorrhœa or gleet has been regularly treated for thirty days, and at the end of that time is no better; if during all this time the surgeon has reason to think that the patient has given the treatment fair play, and finally, if there be no complication, such as swelled testicle or abscess in the perinæum, my opinion is that it will not be cured by the ordinary remedies more than once in fifty times; nay, I question if any benefit result from employing them: and could we attain to a sufficiently accurate diagnosis at the outset, it would, I think, be better to resort at once to a different plan. But I know of no means of doing this,—and the only rule I can find for using extraordinary measures is the failure of others.

Again and again have I in such cases, at the wish of the patient, or from a desire to avoid recurring to my last resource, tried one medicine after the other, and injections of all kinds. The result always was, either that the patient left uncured, that some complication sprung up, or that a cure—if effected at all—was wrought by some totally different means. I have now given up this plan, convinced that if one medicine fails, a second has just as little chance.

It may be said that this is a very short time to fix for a trial, but I can scarcely recal a case of cure where there were no signs of amendment within a month. Delay is perilous; while we are trying to cure the discharge, stricture may be at the bottom of the mischief.

When a patient with long-standing gleet only comes under treatment at an advanced stage, the first step of all is to make out the history of the treatment. Many of these cases last so long solely because no pains have been taken to secure a different result.

Thus, in one case the disease had existed twelve months, but the patient had only taken pure copaiba and sweet spirit of nitre: a cure was effected in three weeks by the daily use of an injection of nitrate of silver. In a second, the gonorrhœa had lasted five months; but on cross-questioning the patient he admitted having neglected it: it was cured in a few days by mild aperients and sulphate of zinc injections. In a third, the patient said he had had it off and on for eighteen months. His plan had been to go to a surgeon for three or four months, and if not relieved to betake himself to another—thus perpetually beginning treatment anew. He reaped the results in the form of a stricture. A fourth patient had been treated at intervals for twelve months by injections, and at the end of the time had not yet learned to give himself an injection properly.

In order to make a purely practical arrangement of the subject, I purpose to eliminate all cases with such complications as stricture; next to join all varieties of gleet, except discharges of pure mucus, to gonorrhœa, for they are only one disease; and finally, divide this disease into four classes.

(To be continued.)

M. Schiff's experiments on the subject of Diabetes seem to settle the heretofore debated question—how the sugar comes to accumulate in the blood. The two theories held on this subject were:—1. That the actual quantity of sugar formed was abnormally great, in consequence of increased activity of the liver in its formation; and 2. That the quantity formed in the liver was not actually greater than normal, but that the ferment (an hypothetical agent) which caused its transformation in the blood was defective, and therefore the sugar accumulated. M. Shiff apparently decides the question. According to him the excess of sugar in the blood, as found in artificially-produced diabetes, results from an excessive formation of sugar in the liver. M. Shiff found that diabetes could be produced by the induction of an hyperæmia! He found the same thing result on removal of the spleen, whereby the liver was congested. 'Medical Times and Gazette.'

CASE OF MUSCULAR RHEUMATISM CURED BY NARCOTIC INJECTIONS.

By J. H. PARK, M.D.

D. P., aged about forty, a man engaged in cleaning the locomotives at the railway, consulted me about the middle of June for a pain in the left hip, which had rendered him so lame as to incapacitate him for work. The nature of his employment obliges him occasionally to lie on his back on the ground under the engine, the ground being occasionally damp,—and he attributes this as the cause of his complaint. His general health is not great, but still he is able for a good day's work. On examination, the muscles of both hips were much the same in appearance, being rather flaccid. The pain complained of corresponds pretty accurately with the space occupied by the glutens maximus, and is increased by pressure; it affects him most when rising up in bed, or from the sitting posture. I came to the conclusion it was a case of muscular rheumatism. I put him on cod-liver oil with iron, gave him sharp purgatives, and ordered warm hip-baths at night. This treatment, persevered in for a fortnight, gave no sensible relief. He next tried change of air, and took iodide of potassium for about three weeks, obtaining a little relief, which, however, was only temporary. The pain increased, with frequent paroxysms of great severity, obliging him to scream out. He lost sleep, strength, and spirits; and, to use his own expression, the constant pain or aching was "tearing the flesh off his bones." He was confined entirely to bed; the moment he attempted to stand up, he fell, or would have fallen to the ground had he not been supported.

On two successive nights he took half a drachm of the liq. opii sed. (Battley) without any effect whatever. I then determined to try the narcotic injections, and I am happy to say they had the effect of entirely curing him. I injected at four different parts of the muscle 5 minims of Battley. After injecting in two places, I allowed an interval of two or three days to elapse, to observe the effect. The very day after it was done, he was able to stand; the pain was not entirely removed, but very much better. The next two injections completed the cure, and he now walks about almost with his usual freedom. I only regret now that I had not recourse to the operation earlier, as I have no doubt it would have saved the man much suffering. With Wood's syringe the injections are simply and most effectually accomplished, as in this instance; and, I doubt not, in all similar cases will be found of the utmost service.

Broughton Ferry, Aug. 16th, 1860.

THE SPIRIT OF THE PERIODICALS.

Mr Hilton continues the publication of his Lectures on *Pain and Rest* in the 'Lancet,' and Dr Patrick Fraser his papers on *Stimulation versus Depletion*. We quote the present part.

"Third Epoch.—*(From Paracelsus to Harvey.)*

"In the fifteenth century Paracelsus commenced a reformation in medicine—a man who, 'with all his faults,' did good service as a thorough reformer to the science of Physic. It is quite certain that a man of his temperament would not stop short in the employment of any remedy promising to effect sharp and speedy cures. We consequently find that he practised venesection: but under what, if any restrictions, we have no information. A reaction now took place, and Botelli, in 1577, advocated excessive bleeding, to the extent of two or three pounds at one operation, and this repeated four or five times at short intervals.

"The cases on record of the large quantities of blood which have been lost without apparent injury, would lead to the conclusion, that the average quantity of blood in the body—viz., 30lbs. in the adult—has been under-estimated: for example, 'A phlegmatic man lost by the nose, mouth, and urine, eighteen pounds of blood; and yet there remained so much in him, that on the application of cupping-glasses, they were instantly filled with blood.' (Schenck, Obs. Med., i., p. 172.) Brapavolus had a lady under treatment, in whom twenty-two pounds of blood passed from the nose; she recovered by the use of several remedies, 'one whereof was phlebotomy.' (Comment. ad Aphor., xxiii., 15.) Marcellus Donatus (C. xxiii.) gives a case of eighteen pounds of blood issuing from the nose. Amatus Lusitanus relates a case where, within five days, twenty pounds of blood passed from the nose; another, forty pounds in six days, 'whom he yet cured by phlebotomy.' Montanus says he 'cured one of the emeroids, which bled every day for forty-five days, two pounds of blood and more.' (Schenck, Obs. Med., xiii., p. 342.) Anculanus gives a case of twenty-five pounds of blood being lost in three days from a wound, and recovered; and several others are related, in which six and twelve pounds of blood were voided by the nose in a few hours, or days, but recovery always took place. Riolan has taken, in twelve hours, five pounds of blood without injury. He estimated that half the quantity of blood in the body might be extracted without danger; and as he considered the whole quantity of blood varies in different nations, he arrived at the estimate, that a German may lose fifteen pounds; a Frenchman, ten pounds; Spaniards, Moors, Asiatics, less in the order of their standing. That Botelli had supporters in the practice of excessive depletion, we know from Astens, a writer in 1583, who argued that ancient as well as modern physicians erred in bleeding too little rather than too much. Van Helmont, at the same period, although he did not denounce venesection, exposed the evils arising from excessive depletion. Although we are not prepared to subscribe to his celebrated motto, 'Ego sane nemini sanguinem mitto,' still it is a fair question whether the excessive bleedings enjoined by Botelli and his followers were not more injurious than the total rejection of venesection by Van Helmont and his followers. Various writers—for example, Almarico Blondelo in 1620, J. F. Buchone in 1629, Stahl, Thouvenal, Martianus, Lancisi, Baglavi, Pascoli, Forestus, Peater, Hoffman, Amatus, and, last, Victoris Trancavellus, supported more or less the doctrines of Van Helmont; but, to the credit of most of these men, their condemnation of bleeding did not extend to the utter exclusion of it as a remedial agent, but to the avoidance of its abuse only. The last-named writer enters more minutely in his condemnation by designating the diseases in which venesection ought not to be practised—viz., delirium, epilepsy, paralysis, catarrh, ophthalmia, nephritis, hypochondriasis, continued fever, scirrhus uteri, suppressio mensi, menorrhagia; ending by saying, 'Nos non debere nimis proclivis nimisque liberales esse in detrahendo sanguine, ne dum Scyllam fugimus in Charybdem incidamus.'

"We see from the foregoing, that bleeding has been employed as a remedial agent from the earliest period of the history of the human family, but upon the most opposite and sometimes illogical principles.

"Fourth Epoch.—*(From Harvey to the middle of the Eighteenth Century.)*

"We now arrive at the important period when Harvey, in 1619, first publicly taught the doctrine of the circulation of the blood. It might be expected that, upon this great discovery, the wavering opinions as to the practice of bleeding would have become fixed and certain; but this consummation, 'most devoutly to be wished,' has not been realized; the same discrepancy of opinions and vacillations in practice are manifested in the writers of the period now under consideration. Unable, apparently, to determine on the real question whether, in certain diseases, venesection should or should not be performed, the writers now busied themselves in angry discussions as to which vein should be opened in certain diseases, such as veins of the arm, hand, ankle, foot, tongue, nose, canthii majores, temple; in fact, each part of the body had some one to assert its priority. Matthæus Curtius, in the fourteenth century, enters fully into this question; and about 1534 several writers gave opinions very learnedly on the subject. For example: Leonardi Fuchsii—'Apologia contra Hieremiam Thrinerum de Venesectione in Pleuritide'—taught that the vein of the affected side ought to be opened; whereas Andreæ Vaesalii at the same period affirmed just the contrary; and it is not until the year 1741

that M. Martin, in his treatise, gives such instructions as may be followed with safety and propriety at the present day. He tells us that bleeding is indicated when the patient is in the flower of his age, the strength unimpaired, the complexion good, the pulse equable, full, and strong; if he has had previously good nourishment, and if there is general heat of surface and no organic disease: that it is contra-indicated when the patient is enfeebled and the constitution not strong, the skin and extremities cold, the pulse feeble, soft, and intermittent; if the patient has led a laborious and badly-nourished life; and if there should be organic disease. Sebastiono Bado, in 1663, asserted the absolute necessity for venesection in small-pox, and the other exanthemata. Also M. Patin, a famous physician of Paris, writes in the year 1680, 'There is no remedy in the world which does more miracles than bleeding.' On the other hand, we find Ramazzina, Richter, and others strongly condemning it.

"At the same period, equal differences of opinion prevailed amongst our own countrymen. Sydenham (A.D. 1666) says: 'Primum in curatione locum phlebotomiæ attribuo, quæ sine salutis periculo hic omitte nequit.' Heberden says: 'Febres ardentes raro sanantur sine detractione sanguinis copiosa et repetita.' We have a treatise in 1665 by Joannis Franciscus de Francisco, 'De Hodierno Practicantium abusu Sanguinem Mittendi semper in Febribus.' There is also a most elaborate treatise by Henry Stubbe, a physician in Warwick in 1671. He defends the practice of phlebotomy against the 'audacious and impertinent strictures,' of 'one G. Thomson,' contemptuously called 'Bacon-faced,' a 'pseudochemist,' and a 'pretended disciple of my Lord Vernlam.' This said G. Thomson seems to have had certain strong and not always incorrect opinions upon his subject. He tells us that 'We are taught by Divine Writ that in the blood—the spiritus rubeus—is life;' that 'one would think that it should put a stop to their prodigal, profuse bleedings, if they did but consider with what difficulty nature brings this solar liquor to perfection.' He was no fool when he observed, 'They should never attempt—yea, rather abhor—to enervate in the least, by the lancet, the strength with its correlative blood and spirits, without which there is no hope of a cure; for,' he adds, 'manente causa, manet effectus.' That Dr Stubbe was honest in his belief as to the efficacy of venesection is fully evinced by his 'practising what he preaches.' He tells us: 'In short, I have myself been let blood above fourscore times, and yet am lean; and so far from being favourishly inclined, that I never had any, except the measles once, and small-pox twice, and twice a tertian ague.' Rejoice, ye physicians of the present time, at your exemptions!

"An array of learned theses during this epoch, and closing in upon the end of the century, upon this universal subject,—'De Recta Sanguinis Missione,'—sufficiently attest the divided spirit of the time:—Dr White, in 1712; John Van Coxie, 1723; Dr Mentyles, 1744; John Huggan, 1771; Francis Cuel, 1775; William Drennan, 1778.

"Fifth Epoch.—(*From 1750 to the present time.*)

"It is manifest that our forefathers were fully alive to the difficulties involved in the question of the employment of venesection in disease, also to the necessity for care and discrimination in its application; that they held in view the age, sex, temperament, condition of patient, climate, and prevailing diseases; that they were, as we are, often sorely puzzled by discordant opinions; and it is painfully evident that in ancient, as in modern times, blood has been let when it had better not, and not let when it had better been let. Clutterbuck felt this strongly, and he, not very logically, comes to the conclusion that bleeding is useful when it is useful, and hurtful when it is hurtful; somewhat like the justice, who, in his summing up in a doubtful case, consoled himself by remarking, 'If I'm right, I'm right; and if I'm wrong, I'm wrong.'

"Several writers allege that the change from depletion to stimulation dates from the first invasion of the cholera morbus in 1830; but we have in evidence that it began much earlier—in fact, that similar discussions date from a very early period. Lind, in 1774, in his essay on the 'Health of Seamen,' p. 159, says that the physicians in the West Indies began to doubt the benefits of venesection. Hewson, in his original paper, (vol. lx., p. 406, 'Philosophical Transactions,') doubts the propriety of bleeding. That Cullen had misgivings is obvious. In book i., par. 139 and 362, of his 'Practice of Physic,' he says, 'Nothing is more evident than that bloodletting is one of the most powerful means of diminishing the activity of the whole body.' 'It is, however, to be attended to, that a greater evacuation than is necessary may occasion a slower recovery; may render the person more liable to a relapse, or may bring on other diseases.' (Par. 140.) 'From all this it must appear that the employing bloodletting in certain fevers requires much discernment and skill, and is to be governed by the consideration of the following circumstances:—1st, the nature of the prevailing epidemic; 2nd, the nature of the remote cause; 3rd, the season and climate; 4th, the diathesis present; 5th, the period of the disease; 6th, the age, vigour, and plethoric state of the patient; 7th, the patient's former diseases and habits of living; 8th, the appearance of the blood already drawn out; 9th, the effects of the bloodletting that may have been already practised.' (Par. 142.) It may be seen that Galen and Trancavellus had long before laid down similar rules.

"M. Freteau, in 1816, says: 'De nos jours les constitutions sont moins fortes, les individus moins pléthoriques, les maladies franchement inflammatoires moins communes.'

"So early as 1817, Dr Christison noticed a change in the treatment of fever; but especial attention was drawn to this subject by him in 1834. He writes thus: 'Our patients ceased to sustain free venesection, a few ounces of blood bringing on faintness, and the constitution refusing to rally afterwards.' The contrast of the foregoing observation with what he writes in his thesis in 1819 is most remarkable. He there describes the 'pulse being at 100, hard, and incompressible; the temperature of the body at 107; and the blood spouting out with amazing force on opening a vein.' At the same period of time, Dr Mackintosh, a man of great energy and originality, who had for many years advocated strongly the practice of bleeding, especially in the cold stage of ague, writes, in vol. i., p. 472, of his 'Practice of Physic,' 'within the last fifteen years I have seen several cases where considerable injury had been inflicted by very large bleedings.'

"In the year 1820, a strong reaction party existed in the College of Edinburgh, as indicated by several theses of that date, in favour of venesection. The following are examples: William Garland says: 'Inter omnia remedia ad morbos varios sanandos, quibus corpus humanum obnoxium est, nullum majore effectu vel eventu feliciore quam sanguinis detractio adhibetum.' John Barne (1821) says: 'Medici omnibus sæculis missionem sanguinis remedium esse eximium arbitrati sunt.' John Halkenston (1821): 'Nostrorum temporum opiniones variæ sunt sed in universum medicorum animi magis de hoc remedio, quam de plerisque aliis consentiunt.'

"It was about this time that we have it also recorded by truthful and acute observing physicians,—for example, Gregory, Radcliffe, Alison, Watson, and others,—that they required in their own persons, for acute disorders, large depletions, which were followed, as attested by all of them, with great and unmistakeable relief to their sufferings. We have seen also, in our explorations of the writings of ancient as well as modern authors, that the employment of bloodletting, as a remedial agent, was not always in a fixed ratio. Unfortunately, the Medical writers of the different periods simply state the fact, but have not left us information as to their opinions of the causes. That causes do exist seems certain, for surely the cessation in the employment of bloodletting has followed, and not preceded, the change.

"We have now reached a period in which even more angry and censorious discussions took place than heretofore, between men whose opinions demand reverential, careful, and watchful attention. Dr Alison and Dr Bennett were the champions. Both agreed as to the fact of a change in treatment having taken place, but differed in opinion as to the cause or causes. The former attributed it to an alteration in the type of disease, thereby inferring some occult change in the human constitution; and if this be the truth, we may also truly infer that the excessive bleedings practised by our forefathers were probably quite right and necessary, thus rescuing their mode of practice from the unmerited obloquy which has been cast upon it by several writers. Dr Bennett places the change to an increased knowledge in the art of diagnosis. We have no intention of entering minutely into the merits of the late controversy, but we would observe, that it appears to us that Dr Alison, in allowing his antagonists to apply their arguments to pneumonia alone, weakened his ground; for if this improved diagnostic power be worth anything, it ought to apply to all diseases, which is not attempted; but to all diseases the limitation in bloodletting applies. Again: we admit that through our increased diagnostic power, we are better warned not to bleed in pneumonia after consolidation of the lung has taken place. But this does not explain why even in the acute stage of crepitation bloodletting is seldom resorted to now, but which would have been practised thirty years ago, *pleno rivo*, even in the absence of the assumed superior diagnostic power, and with great benefit to the sufferers; neither will it explain the advance in the use of stimulants *pari passu* with a decrease in the employment of depletants.

"Drs Christison, Alison, and others, have alleged the change in the type of disease to proceed from certain atmospheric influences. The former dwelt strongly upon the impoverished state of the poor population, evinced by the scorbutic diathesis, and the prevalence of cholera; but the fact that all ranks of the people, from the patrician to the peasant, have become subservient to the change, invalidates poverty as the main cause, and we know that the change had begun long before the modern cholera appeared. This party does not, as has been alleged, declare that the *modus operandi* of inflammatory action, or its effects, is changed; but simply that inflammation is not now attended by high arterial action.

"It has not been, and probably never will be, proved what causes are in operation to effect the remarkable variations which have occurred in the symptoms of disease; and in our anxiety to appear to have some definite views, we are almost impelled to the *non causa pro causa*.

"We can scarcely avoid the conclusion that certain causes are operating in cycles; that, in fact, the human family are subjected to periodic changes, impressing, as it may happen, a sthenic or asthenic character on the prevaling diseases. If this idea should be recognised as a fact, the extraordinary discrepancy of opinion as to the curative value of bloodletting would be reconciled and explained. That this change is not merely local, but pervades the length and breadth of the land, and that it has been recognised throughout Europe and America, is shown by the general intolerance of bleeding, not only in man, but amongst domestic animals, as proved by veterinary practitioners. In our own experience we have witnessed exemplifications of this change. We remember cases similiar to those commented upon by Stephens, Turnbull, Watson, Symonds, Hastings, Richardson, and others, where the injected eye, flushed face, burning heat of the skin, violent arterial throbbings; the incompressible, sharp, and wiry radial pulsation; urgent dyspnœa, a red tongue, intense headache, and other local pains, unattended with muscular debility, appeared to render bloodletting imperative. Contrast such cases with those, with few exceptions, now witnessed in town and country practice, in which there is little or no heat of skin, no arterial excitement, feeble and easily-compressed radial pulsation; a white, loaded, and flabby tongue; a pearly-white conjunctiva, not much pain, but extreme prostration, urging to the employment of stimulants.

"We have reason to believe that these changes in the type of disease occur sometimes at very short intervals. In China, during the month of February, 1830, an epidemic fever occurred amongst the English sailors, in which the tongue was white and loaded, no arterial excitement, and no pain. In the month of May following, a second epidemic appeared, during which the symptoms were—headache; pulse from 80 to 110, full, and bounding; tongue clean; severe epigastric pain. The following comment was made at the time: 'We believe this fever to be of a different type from that witnessed in February;' and the question is put, 'Is bleeding necessary in both types?'

"The history of influenza will furnish many similar instances. Every one knows the variations which have occurred in the symptoms of this malady, requiring a complete change of treatment. We know, indeed, that from the earliest ages the symptoms and organic lesions have varied in similar epidemics. There have been variations noticed even in the same epidemic at different periods of its history."

Dr W. Baker, of Howden, contributes to the same journal a case of *Double Transverse Hemiplegia*. It is thus described:

"Master H——, aged four years, a quick little boy, was slightly unwell on the evening of the 23rd of September. He was thirsty and feverish, passed a rather restless night, and complained of pain in the back part of the head and neck. Without much change he continued slightly complaining till the 26th, on which day it was perceived he could not carry his head steadily, or bear the erect position, without complaining of greatly-increased pain in the neck. No great importance was attached to his condition by the parents, and their medical attendant, Mr Newstead, was not consulted till the 27th. Even then the serious symptoms which soon followed were not indicated or suspected, and it was hoped that the pain might be muscular. On the 29th, it was perceived that the left arm was paralysed, and the paralysis gradually extended to the right leg—the right arm and left leg being still perfect. On October 1st, the right arm was invaded, and the paralysis gradually increased, and extended to the left leg. I visited him on the 3rd of October. The paralysis was the most complete in the first-invaded limbs; the only power over them was slight movement of the fingers and toes. The right arm and left leg he could flex in a trifling degree, and continued to do so to the last. Occasionally, some slight improvement took place in this arm, to which he would exultingly call the attention of his mother. The spirits and appetite of the little fellow were generally good, and the control of the sphincters was perfect. In this condition he continued, without any important alteration, till the 24th, on which day he showed increased weakness and loss of spirits, and some slight gurgling was occasionally heard in the throat. This symptom continued. He was supposed to be slightly convulsed in the night, and died on the 25th. The intellect throughout was undisturbed; sensation and the sphincters perfect; the respirations rather quick, but never embarrassed; pulse variable, frequently quick; and temperature rather exalted. The treatment adopted — gently and persistently antiphlogistic — the position recumbent.

"I greatly regret that my report of this interesting case should be so defective in the most important part of its pathology; no after-death examination having been made, the anatomical change by which the paralysis was caused, as well as the site of any such lesion, must ever remain in doubt. When the four limbs lose their power, either simultaneously or in succession, and the cause is in the brain, it is presumed that both hemispheres must be implicated; we likewise know that similar effects may follow lesions of the spinal cord alone. In this case I think the mischief was not in the brain, intelligence and facial expression being unchanged, and all the nerves of special sense and also those of common sensation perfect. When the brain sustains an injury above the decussation in the medulla oblongata, and paralysis is the result, the cause and effect are presumed to be invariably opposite or crossed; but in lesions confined to the spinal cord, the effect is said to be as regularly direct, and probably never crossed. Here we have a paralysis of the four limbs—a well-marked double transverse hemiplegia; and in spite of a crossed manner of invasion, I am disposed to place the cause of the malady in the spine. On my visit on the 3rd of October the paralysis was in its most complete state, and, from the history of its approach, with the attendant symptoms, I most certainly deemed it an idiopathic affection of the spine, and pronounced it spinal apoplexy. The pain was confined to the cervical region, greatest at the upper part; there was likewise morbid heat and tenderness, and I presume this was the site of effusion and extravasation, if any such existed—whether of blood or serum is unimportant. Any effused fluid beneath the pia mater of the medulla might travel from the neck to the cauda equina, and the result would be either a complete extinction of sense and motion, or any other degree of modified lesion of either. I certainly am not acquainted with any particular symptom that may be deemed pathognomonic of spinal apoplexy; and for the production of such a condition as I have described, I presume it is not necessary that there should be either effusion, extravasation, or any other detectable lesion, either in the cord or brain.

"Baron Cuvier, in his last short illness, suffered from a transverse hemiplegia; the power of deglutition was destroyed, and his speech greatly altered. He first complained of being unwell on the Monday,—a slight irregularity in the bowels. An enema was administered, and on Tuesday he was well, and delivered his usual lecture at the College, displaying great and unwonted energy, and likewise on the same day used more than ordinary bodily exertions. On Wednesday he felt pain in the right shoulder and arm, with some slight loss of power in the hand. He still attended a state council on that day, and on his return was most urgent for his dinner, during which he experienced great difficulty in swallowing solids. On Thursday he could not move his right arm. There was some headache, and deglutition more difficult, in fact impossible, and for the conveyance of matters to the stomach the œsophageal tube was used. The night was restless, and on Saturday morning there was palsy of the movements of the left leg; all mentioned symptoms were worse, and, in addition, the hands were cold, and the nails blue. On Sunday he was calm, complained but little; his voice was greatly changed, and his appearance ten years older. Harassed and exhausted as he was by treatment and disease, his intelligence still was perfect. At nine o'clock he said his mind was leaving him, and he died a quarter before ten, sitting upright in his chair. The spinal column was cautiously opened, and its contents most critically examined, but no trace of disease was found. The brain, pharnyx, and œsophagus equally failed to present any morbid condition—in fact, in no part of the body could any change be discovered to which the sufferings and death of this illustrious man could be attributed. The Baron was sixty-three years of age. He had taxed his mental and bodily powers unusually, and, in the absence of every morbid change of structure, it is not unfair to presume that his illness was the consequence of exhaustion alone. If such was his condition, the repeated local and general bleedings, blisters, and nauseating enemas, so diligently and vigorously used, must have lessened, if not destroyed, every chance of the restoration of this great man.

"Presuming that my little patient had effusion in the spine, what was the result consequent upon the same within the cranium? There was undoubtedly inflammation, as indicated by heat, pain, and tenderness in the upper cervical region, and the great benefit found by leechings. It is probable that death was caused by an extension of inflammation to the brain."

Mr Raphael Ward, Surgeon to the 30th Regiment, reports a case of *Hydrocele* radically cured by the wire seton.

The 'Medical Times and Gazette' opens with a continuation of M. Claude Bernard's Lectures on *Experimental Pathology;* his present topic being the *Pancreatic Secretion*. After some remarks on certain anatomical points connected with the pancreas in the human species and dogs respectively, M. Bernard says:

"The dog is of course the animal usually employed in making experiments on the pancreatic secretion; and the accessory duct is generally chosen for this purpose. The operation is performed in the following manner:

"An incision is made upon the abdominal parietes in the median line, in the vicinity of the pylorus; the muscles being drawn aside by an assistant, the operator seizes the duodenum with a forceps, separates it from the adjoining parts, and draws it out through the wound. The pancreas, the intimate connections of which with this portion of the digestive tube are well known, is in this manner extracted from the abdominal cavity; the vessels are then drawn aside, the utmost care being taken not to injure them; and a small portion of the accessory duct is thereby laid bare. On this point the incision may be performed, without irritating the delicate gland, which the slightest touch would inflame. A thread being passed under the duct, it is opened, and a silver tube is fixed by means of a ligature in its cavity; it is often found necessary to fasten the tube in the duct in two separate places, in order to prevent it from escaping. The duodenum and pancreas are then carefully replaced within the abdominal cavity, the extremity of the cannula still protruding from the wound. The tube employed for this purpose must be four or five inches long, and provided with a stylet, to clear it from obstructions.

"The pancreatic secretion has not exclusively been studied in the canine tribe; its properties have been examined in several other animals.

"In the cat the disposition of these ducts is so irregular as to baffle all description; in most cases, there exists several of them. In the rabbit this distribution is highly favourable to the experiment; they spread over the mesentery, in the shape of a fan before penetrating into the duodenum; nothing, therefore, can be easier than to open them and insert a tube into their cavity. The anatomical preparation which we place here under your eyes, exhibits the above-mentioned arrangement.

"In the ox the pancreas is equally provided with a large number of excretory ducts; the greater part of these are anastomosed with the biliary apparatus: some of them fall into the ductus choledochus; others arrive at the gall-bladder itself; and the biliary ducts are not unfrequently connected with little pancreatic glands, which pour into their cavity the fluid which they produce. There always exists, however, one independent duct at least, which opens separately into the duodenum; on this point is the operation performed: but even after tying most of the accessory ducts, it is impossible to collect the whole of the liquid secreted by the pancreas, a large proportion of which flows directly into the gall-bladder. We here place under your eyes the duodenum of an ox, with the neighbouring portions of the stomach; and in this preparation you see the ducts which [illegible] the pancreas, freely anastomosed with the various ramifications of the biliary canal.

"The method of obtaining pancreatic juice which has just been described, is altogether different from the one adopted by De Graaf: in his researches on this subject, he used to make a wide incision on the abdominal walls, which allowed the whole intestinal mass to escape; the pancreas being then separated from the neighbouring parts, a tube was introduced into its principal duct; but the subsequent results of this somewhat brutal separation appear to have vitiated the secretion of the gland, for De Graaf's description of the properties of this fluid is far from coinciding with the notions actually entertained on this point.

"Other observers had opened the duodenum, in order to obtain a supply of pancreatic juice; but Tiedemann and Gmelin had recourse to the operation we have described, and were thus enabled to obtain large quantities of this fluid without wounding the intestine. The advantage of avoiding this useless injury is too evident to be explained.

"The operation must in every case be performed while the animal is in full digestion, for in the healthy state the secretion only takes place at that moment, and the nerves of the pancreas being imperfectly known, we are unable to bring galvanism to bear upon them, for the purpose of stimulating the activity of the gland. On the other hand, it is of the highest importance to obtain a certain quantity of the fluid at once; for if several hours are allowed to elapse after the operation before any is collected, an acute inflammation may have taken place, and a vitiated secretion is obtained instead of the normal products of the gland. In most cases, however, if the operation has been properly performed, these accidents do not occur, and the animal furnishes a healthy secretion in abundance, for the space of several days."

Mr Bowman contributes a controversial article to the same journal on *Iridectomy in Glaucoma*. After some remarks in disparagement of a reviewer

in the 'Dublin Quarterly Journal' who condemned the practice of iridectomy, and eulogistic of Professors Donders and Von Graefe, who have given especial attention to the nature of glaucoma, he observes :

"The treatment by iridectomy has been no hap-hazard guess, but a rational conclusion gradually worked out. The dominant idea guiding the mind to the appropriate remedy has been that of the existence of augmented intra-ocular pressure, as the main characteristic of the glaucomatous process. In fact, whatever the essential nature of that process, its concomitant seems to be a marked tendency to hardness or tension of the eyeball ; and thereupon arise the most serious secondary effects,—paralysis of the retina, oftentimes interrupted circulation, congestions, inflammatory attacks, with their various consequences, —ending sooner or later, and with more or less of intermissions, in total loss of sight and a spoiling of all the tissues of the eyeball. The general states met with in practice, and falling under the general heads of amaurosis with excavation of the optic nerve, chronic, sub-acute, and acute glaucoma, all seemed to be allied to one another, and may be termed 'glaucomatous diseases.' Some are very slow in their progress, and the loss of power in the retina very gradual ; there is no inflammation, or even congestion ; in others there is congestion, slight or considerable, intermittent or continuous. In others, again, acute and intense inflammation arises. A glaucomatous state may also come on in the course of other diseases, choroidal, retinal, or cataractous. To relieve intra-ocular pressure seems to be the prime indication in all, and it is rational to suppose that it will be the more effectual, the less deterioration of structure the retina has previously suffered. To relieve this pressure is to disarm the glaucomatous state of its chief peril, and apparently to restore the eye to the influence of the reparative powers belonging to it as a living organ. The tension once relieved, and so long as it remains so, the circulation tends to its natural equilibrium, and the retina which has been compressed recovers itself more or less, or ceases to degenerate, in a degree usually corresponding inversely with the intensity and duration of the preceding pressure.

"It is certain that this critic would never have attacked the new practice had he really read Graefe's memoirs, or believed the cures, reported by others, to be genuine. He says, 'Graefe's doctrines, as published by the Sydenham Society, are plausible, but in a practical science of this nature we require something more than doctrines ; cases must be given, and Graefe was wiser than his countryman of the London Ophthalmic Hospital, and kept his cat in his bag.' Will it be believed that the reviewer can have read the memoirs of Von Graefe which he criticises, which are enriched with numerous cases, fully detailed and epitomised, and constantly referred to, illustrating all the main doctrines advanced ? As for the experience acquired in England, I shall at present speak only for myself ; and I can assure the reviewer, in the most decided terms, of the reality of the influence of this operation in relieving, even permanently, the unnatural tension of glaucomatous eyes, and of its effect in arresting the glaucomatous process, and often in restoring sight in a marvellous manner. My own cases in the hospital and in private have been numerous, and bear out the above general statement. This it is that makes me so anxious that the Profession should be rightly informed as to the signs of glaucoma in its relievable stages, and should be ready to sanction the timely application of the only known real remedy. I can hardly conceive a greater comfort in practice than to be able, by this operation, to rescue sight thus imperilled, and to escape the disheartening task of treating a disease, evidently tending to blindness, by the old, ineffective remedies. The reviewer may class the eminent author of so great a boon with 'Hahnemann, Preissnitz, and De Leeuw,' but he may depend upon it he will be powerless to 'arrest the spread of the "glaucoma epidemic" in England.' I could, indeed, heartily wish that, when he has further examined into the evidence, and dispassionately perused what he criticises, he will make trial of the operation for himself, in which case I doubt not he will be satisfied with his results.

"In speaking in these terms of iridectomy in glaucoma, I must carefully guard myself from being supposed to uphold it as a sovereign remedy equally valuable in all forms and stages of the disease, and under all its various complications. At present the operation is being extensively tried in cases where augmented intra-ocular pressure evidently exists ; and the proved tendency of the operation to relieve this injurious tension, the certain cause of secondary mischief, makes it our duty to employ it, when the patient is otherwise apparently drifting into inevitable blindness. It may be our misfortune, and that of our patients, that our experience is as yet less complete than a few more years will make it ; but meanwhile we can only act on the light we possess, and store up the results for the future benefit of others.

"While the modern doctrine and treatment of glaucomatous affections is so new, it is to be expected that errors in the diagnosis may occur even among well-instructed practitioners ; and the operation is doubtless in some danger of being brought into discredit by being undertaken in cases to which it is not rationally applicable, or by being defectively executed. I do not see how this can be avoided ; it is the necessary fate of all novel proposals, and this one must face the ordeal. It is the part of intelligent men to make allowance for these incidents of human progress, rather than to allow them to prejudice the march of truth.

"In the present state of our knowledge it may be right to try the operation experimentally in some cases to which more extended experience may show that it is not usually applicable. Experience hitherto shows that it is most valuable when performed *early* in *acute cases*, in which turbid effusions exist, the absorption of which goes on rapidly when the tension is relieved. Temporising measures in such cases, such as bleeding, mercury, colchicum, and even simple puncture of the eye, whether of the aqueous or vitreous regions, are not to be relied on, and occasion dangerous delay. It is also most useful if performed in the subacute form, when the visual field is not as yet seriously contracted, but where the symptoms are steadily advancing. If postponed here till the sight becomes greatly impaired by gradual alteration of the tissues of the retina, and of the optic nerve-entrance, the ultimate advantage is smaller, though usually lasting. In many instances we are called on to treat patients already almost blind from the progress of the disease under one or other of its various forms. Here it has often been the means of sparing them a little sight, sometimes permanently, at others not. I have also tried the operation in some examples of blind and tense glaucomatous globes, the seat of excessive or wearisome pain, and on several occasions have been well satisfied with the result. How intractable such cases are apt to be under the usual palliatives is well known.

"As for the operation itself, a large experience has convinced me that, though usually a simple proceeding, not liable to accidents, it is occasionally one of the most delicate and critical in its nicety of all the operations on the eye. The anterior chamber has to be entered at its extreme rim, where the sclerotica overlaps the cornea, close in front of the iris, which often bulges much, and which must on no account be pricked, lest the vitreous humour or the lens, immediately behind, should be wounded ; in either case a most serious complication. The bulging of the lens, in many cases, and the dilatation of the pupil, add to the risk of injury to the lens. A little blood, too, escaping into the anterior chamber, either before or after the excision of the iris, may obscure the parts from view, and add to the chance of involving the vitreous humour or lens. It is obvious that these difficulties and contingencies ought to be acknowledged and recognised in order that they may be guarded against. In very few instances indeed can they lead to accidents in skilful hands. When blood occupies the anterior chamber in the course of the operation, it is wise to remove it, either by a gentle stroking movement of the *curette* over the cornea towards the incision, or, if that do not suffice, by carefully introducing the end of the *curette* within the incision itself. On two occasions only have I known the lens to become opaque after the operation, where the capsule was not directly injured (as it ought never to be) by the instrument. One of these was in my own practice, another in that of a highly-esteemed colleague.

"I am unwilling to extend this already long comment on the review by any inquiry as to the *rationale* of the operation ; but there is much in favour of Von Graefe's original suggestion, that the diminution of intra-ocular pressure may be largely due to the lessening of the iris as the surface secreting the aqueous humour. My own opinion, however, was, and is, that the more direct communication opened between the vitreous and aqueous regions of the eye facilitates the play of currents between them, and thus allows an excess of fluid behind to come forward to the corneal surface, through which exosmosis is much easier than through the posterior coats, the sclerotic, choroid, and retina. This would go far to explain the apparently contradictory influence of the operation in raising the tension to the natural degree when previously diminished ; for this also it is capable of doing in some cases, as shown long ago by Von Graefe himself. That the size of the piece excised in glaucoma has a direct relation to the effect produced is true according to his latest observations, confirmed, I believe, by those of Donders, and of Arlt, the distinguished and most able Professor of Vienna. I can also add my own corroborative testimony. Von Graefe is thus led (in his latest memoir, just published) to insist once more, as he had done in his first paper, on the necessity of removing a considerable portion of the iris (not, however, so much as a third, or even a fourth, of its circuit), where it is wished to reduce permanently the intra-ocular pressure. A small iridectomy is insufficient, much less any mere puncture, such as some are still inclined to rely upon.

"In conclusion, I may remind the reviewer, that after the reading of Mr Hulke's excellent paper on the Pathology of Glaucoma, at the Medical and Chirurgical Society, on January 12, 1858, both Mr Critchett and myself endeavoured, from our own experience, to enforce the importance of Von Graefe's new proposal (see the 'Medical Times and Gazette,' January 23), and that in our weekly operations at Moorfields all comers have had the opportunity ever since of watching the progress of our numerous cases, as well as of those of our colleagues. Mr Hulke advocated and explained this treatment in detail in an able paper 'On the Surgical Treatment of Glaucoma,' in the 'Medical Times and Gazette,' March 27, 1858 (vol. xxxvii., p. 316), referring to the favourable experience of Moorfields and to my own private practice, in which at that time I had the advantage of his assistance. He has recently reverted to the subject in a second paper at the Medical and Chirurgical Society. To both these latter communications I venture to draw the attention of Practitioners. The reviewer is in error when he states that there has been any holding back of opinions or of facts on the part of those who have introduced the operation into England."

Mr Spencer Wells contributes to the same journal a report of *Four Cases of Ovariotomy.* The first case was a successful one, the second case unfortunate, and Mr Wells thus explains the cause of death :

"I am disposed to attribute the death in this case partly to imperfect recovery from the shock of the operation and the consequent exhaustion, and partly to the absorption of some morbid product of the decomposing cyst. When a pedunele is secured outside the wound on the surface of the abdomen, the portion of cyst or pedunele strangulated by the ligature becomes quite putrid in a very few hours, and a black offensive discharge is generally very copious. The same thing must occur when the stump is within the peritoneal cavity, and the effects might be expected to resemble those produced by the injection of putrid substances into the veins. It is known that Dr Clay thinks it better to leave the stump within the abdomen, and acts up to his belief; but, with two exceptions, I have always kept it outside,—this case, and one in which the patient recovered."

The third and fourth cases were also successful. We quote the following remarks upon the cases :

"I am anxious to direct special attention to

the simple after-treatment pursued in these cases,—as I am convinced that in many unsuccessful cases the fatal result has been principally due to over-active or meddlesome medication. The published reports of more than one case clearly point rather to opium than to ovariotomy as the cause of death. In other cases stimulants seem to have been given in mischievous excess; while the opposite treatment by starvation and purgatives is not yet absolutely exploded. I have made a great number of experiments on dogs, rabbits, and guinea-pigs, in order to determine the best mode of uniting wounds of the abdominal parietes; and nearly the whole of the animals operated on recovered,—yet the rabbit is peculiarly liable to peritonitis, and the guinea-pig in about the same degree as in the human subject. But, although no after-treatment whatever was adopted, and the animals were left with their ordinary supply of food, and to their natural instincts, they recovered with hardly an exception. This experience has led me to regard perfect rest in a well-ventilated room, comfortably warm bedding, and extreme cleanliness, while simple food and drink are given in small quantities as the patient's feelings suggest, as the principal things to be attended to. The application of warmth and moisture to the abdomen is very pleasant to all such patients, and undoubtedly useful. Opium in sufficient doses to relieve pain is also of great use; but in larger quantities it is unnecessary and injurious. If given by the mouth in any form it is apt to be followed by vomiting, but this evil is in a great degree avoided by injecting it into the rectum. Here also it seems to have a local soothing effect, especially in relieving irritability of the bladder, which is sometimes troublesome. Purgatives on the one hand, or artificial constipation by opium on the other, seem to be equally mischievous. Over-excited peristaltic action may produce peritonitis directly, while the opposite condition may do so indirectly, and certainly leads to distressing flatulent distension of the intestines. It seems to be a perfectly safe rule to allow both stomach and intestines to adapt themselves to their altered circumstances with very little, if any, medical interference, and certainly rather to do nothing than to run any risk of doing harm."

Dr Moore contributes an article, translated from the 'Hygiea' for October 1859, *On Malformation of the Root of the Nose*, by Professor A. Retzius. A *Case of Lithotomy in a Female*, in which a large stone was removed with success, is reported in the same journal, by Mr Edward Atkinson. The case is interesting.

"Esther ——, a Jewess, aged fifty-four, resident at Jaffa, came to Jerusalem last March, on account of great pain and difficulty in passing her urine, which had existed more or less, for nine years. On examination, the presence of stone was detected in the bladder. She was admitted an in-patient of the English Hospital on April 17, and consented at once to an operation, as her sufferings were extreme. On the 19th I introduced Weiss' dilator (without anæsthesia) in order to relax the urethra preparatory to the operation, which was fixed for the next day, and gradually separated the blades until I was able to touch the calculus with the point of the finger; but, as the bladder was empty, and the dilatation caused considerable pain, I desisted, and withdrew the instruments, without having formed any estimate of the size of the stone.

"20th.—The patient being put in position, and brought under chloroform, I introduced a straight-grooved staff into the bladder, and, striking the stone, carried the point of the instrument round a portion of its circumference, to get an approximate idea of its size. Finding it much larger than I had anticipated, I relinquished the hope of removing it without dividing the firm fibrous ring at the neck of the bladder; and, at once turning the groove downwards and outwards towards the left side, introduced a blunt-pointed bistoury, and incised the whole length of the urethra, increasing the dimensions of the wound as the blade passed outward. Next I made a similar incision on the right side, with the exception of leaving the neck of the bladder untouched. I now applied the dilator (Weiss') slowly, and with occasional pauses, until I could easily place the forefinger upon the stone. Then, withdrawing the dilator, I introduced the forceps, and with some difficulty adjusted its blades over what I now perceived must be a very large stone. Had I possessed a lithrotrite, I should now have broken the calculus before proceeding further; but, as I had none, and dreaded the thought of being obliged to put my patient to bed again without having relieved her, I gave the forceps carefully into the hands of an assistant, and bidding him use gentle traction towards the left side, I again passed the staff on the right, between the stone and the neck of the bladder, which was now on the stretch, and with the bistoury freely divided the tense fibrous band, which seemed too tough to yield to any degree of dilating force. Even then, on making traction with the forceps downwards, and in the mesian line, with oscillating movements, I made but little advance, and it was not until I had again recourse to the knife to deepen the left incision, and after some rather hard, but steady pulling, that I at last extracted a stone, whose circumference, in its short axis, measured four and a half inches, and in its long, six inches; it weighed nineteen drachms.

"So completely did the chloroform answer its merciful end, that the patient did not recover her consciousness for a quarter of an hour after her removal to bed, though the operation had occupied, from first to last, an hour and a quarter.

"After such extensive injury to the urethra, &c., it was to be feared that serious consequences were inevitable; but, strange to say, not a single bad symptom showed itself. Half a grain of muriate of morphia, rubbed up with a little lard, was introduced into the rectum by means of a bone suppository syringe, and fomentations applied to the vulva. On the next day a piece of a gum-elastic catheter was introduced into the bladder and retained there, with a morsel or two of soft sponge upon the wounds, which were changed occasionally. For several days there was a good deal of fever, but this gradually subsided. The patient slept well with the aid of mild opiates. Appetite soon returned.

"On the sixth day a small slough came away, and a healthy contraction of the wounds set in. The catheter was now changed, and a stopper fitted into it, which was removed frequently, so as to prevent as much as possible the urine from flowing over the wound. She drank copiously of water and weak lemonade, so that there was a constant secretion of urine going on. Finding the catheter irksome, the patient removed it herself, and on the tenth day she was able to hold her water for a quarter of an hour. A week later she retained it for half an hour, and was able to walk about the ward a little. Eighteen days after operation she left the Hospital, and a [illegible] to consult me about a slight pruritic eruption on her chest. I have seen her again lately (two months after operation), when she was walking in the street at Jaffa, in excellent health, though still troubled with inability to retain her urine for long together."

Mr Thomas Moore Sunter contributes to the 'Dublin Medical Press' notes on *Delirium Tremens*. We quote the history of the cases:

"No. 1.—A European sergeant serving in one of the West India regiments, who had been eighteen years soldiering in India, and who, according to his own statement (if it could be relied on), had had several previous attacks of 'D. T.' (as delirium tremens is somewhat familiarly styled in the West Indies), was attacked with this disease at Nassau, in the Bahamas, in the month of June, 1858.

"He was an Irishman, of spare, wiry frame, and apparently of an irritable, excitable temperament, between thirty and forty years old, but looking more. His complexion had that tarnished hue supposed to be symptomatic of chronic intemperance. He had been some days ill when I was called to see him by one of the Assistant-Surgeons, and had been treated with calomel and jalap purges, purgative enemata, a blister to the nuchæ, and was then taking chloroform, brandy, and opium, but without any effect on his symptoms, as he had not slept, it was said, for several nights, was talkative, &c.; in fact, he presented the usual symptoms of the malady. His face was flushed, and manner very excited.

"On thinking over his case, I said to myself, Here is a man who has been plied continuously with brandy, with no other effect apparently than to excite him the more; so I shall stop all alcoholic stimulants with him, and as his symptoms seem to be of a character that will be met by the combination, I shall give him tartar emetic with opium. I did so, adding ammonia and camphor to the mixture. After he had taken some half-dozen doses of it, he fell into a sleep of three or four hours' duration, and awoke comparatively composed and sensible. He continued to improve for the remainder of that day, night, and next day. The following morning, however, he was reported not to have slept, and all his symptoms had evidently returned, with the addition that he began to shew symptoms of debility.

"I was hardly prepared for this relighting of his symptoms; the conventional idea in the last cases of delirium tremens I had seen some nineteen years previously having been, that if you could get the patient to sleep all would go on well. So, calling to mind that I had either read in that invaluable refuge for the destitute of medical resource, Graves' 'Clinical Medicine,' or heard Dr Graves state some time or other that he had found turpentine a valuable medicine in certain anomalous conditions of the nervous system, I prescribed it in a mixture of camphor, ammonia, and laudanum, an ounce every second or third hour. After a few doses of it had been taken, he fell into a profound slumber which lasted a day and a night, and awoke quite well.

"No. 2.—A few months later, I was called in the middle of the night to another European, or white sergeant, as they are called in the West India Regiments. I found him under the influence of liquor, and with one of the alar cartilages of his nose cut open from a wound supposed to have been inflicted by his wife, of whom he was said to be jealous, and who was in the room with him.

"The wound was dressed, and he was directed to attend at the hospital in the morning. He did so, and, from the symptoms he presented then, he was admitted. He was an Englishman, of phlegmatic temperament, rather powerful frame, and had served about eighteen months in the West Indies in a black corps, so well as I can recollect, and for some months there in a white regiment also. From the symptoms he presented on the morning of admission, he was given by a very intelligent medical officer (who had seen a good many cases of 'D. T.' during his seven years' service in the West Indies) at eight a.m. a drachm of laudanum in an ounce of brandy. This was repeated at noon, and again at six o'clock p.m. From having been suspiciously quiet in the morning, he became so violent as the day advanced, and made so many attempts to jump out of the hospital windows, although attended by two powerful fatigue men, that, much against the will of the young gentleman who had called me to see the case, and my own, we felt obliged to have recourse to a straitwaistcoat. On visiting him at half past-six o'clock p.m., I found him bathed in a warm perspiration, face pale, and making continued efforts to set his hands and arms free; his pulse being very weak and quick, and he appeared to be about to commence sinking. As the draught he had taken of brandy and laudanum at six o'clock appeared to have produced no more effect on his symptoms than if he had taken so much cold water, I at once prescribed him a drachm of aromatic spirit of ammonia, an ounce of camphor mixture, a drachm of tincture of henbane, and a quarter or half a grain of tartar emetic. In an hour after he became comatose, and died at ten o'clock p.m. It was his third attack of the disease. At the post-mortem examination, in addition to the usual evidences of chronic irritation presented by the gastric mucous membrane, the brain was found to be pale on section and as soft as soft butter, with red effusion into the ventricles and at the base of the brain. The heart was large, soft, pale, and flabby.

"No. 3.—In August, 1859, at Belize, British Honduras, I was called by my assistant to see an officer of apparently thirty-eight or forty years old, an Irishman, sanguine temperament, full habit, his complexion when in health being of a beetroot colour, and at times, as after dinner, of even a purplish hue. No account could be got of his previous history, but he looked like a 'votary of the jolly god;' yet, as the authoress of that

beautiful tale, 'Mr Gilfil's Love Story in Scenes of Clerical Life,' remarks, 'Gluttons are often thin, and sober men are often rubicund.' It was thought he had been for some days under the treatment of a civil practitioner before a military medical officer was called to him. He was first seen by my coadjutor, a clever practitioner, who, during his seven years' West Indian service, must have had a pretty considerable experience of delirium tremens. He prescribed five grains of calomel at bed-time, and followed it up next morning with a Seidlitz powder, which freed his bowels, and in the course of the day brought me to see him. At this time he presented the fidgetty, nervous manner of persons about to be attacked. We prescribed him a drachm of tincture of henbane in an ounce of camphor mixture at bed-time, and procured him the attendance of a nurse. His appetito was reported to be tolerable. I was called to him at six a.m. next morning, and found he had closed the door of his house, and turned out the nurse and all the inmates, who seemed to be quite in a fright, informing me that he had got possession of his pistols, and threatened to shoot somebody. I at once went to his house, opened the door, and found him walking about the house in his shirt. He begged me to send away the fatigue-men—a few soldiers directed to remain about the house on pretence of minding it, but to prevent his injuring himself, as he did not, he said, want any attendance whatever, though he was sure I did it for his good. His pupils were contracted to pin-holes, and conjunctivæ of a fiery-red colour (ferrety-eye). He at once was given a drachm of laudanum, with directions to repeat it in two hours if he did not sleep.

"Noon.—Got a second draught at nine a.m.; no improvement whatever in his symptoms; he could not be got to rest quiet a minute in any position, but kept lying down in bed, getting up again, sitting down, and conversing on some subjects sensibly; appetite reported to be good. Ordered to take every second hour one ounce of the following mixture: R Chloroform, ʒi.; laudanum, ʒi.; aromatic spirits of ammonia, ʒii.; camphor mixture, ʒvi. Brandy in small quantities allowed all through.

"Six p.m.—No change whatever in the symptoms.

"Ordered an ounce every hour of the following mixture: Chloroform, ʒij; tinct. opii, ʒij; camphor mixture, ʒvj. After taking one dose of this mixture, the only and the last dose he got of any medicine, he was reported to have become very violent. At about eight o'clock p.m. he was reported to have had a fit, after having tried to jump over the verandah attached to his house. I saw him at half-past eight p.m.: he was then lying on a sofa; face pale; breathing calmly, as if asleep, but making no reply to questions, and seemingly unconscious. Continued in this way, and died at ten o'clock p.m.

"*Post-mortem Examination fifteen hours after death.*—Body well nourished; cellular tissue loaded with fat; brain soft pale; red effusion into ventricles, and at base; mucous membrane of stomach soft, pale; at greater curvature it was of the colour of old mahogany, with numerous bloody points interspersed; liver was three times its natural size; its colour externally and on section like glazier's putty; fatty liver (?); spleen large, congested; kidneys large, congested; heart large, flabby; no præcordial effusion; no valvular disease; effusion of about a pint of red serum into peritoneal cavity of right side; gall-bladder full of yellow bile; enormous tympanitis; cornea and arachnoids opaque. The former was transparent during life.

"I shall now give the notes of the case of a man who died of poisoning by alcohol:—

"No. 4.—A young soldier of one of the West India Regiments, in the month of February, 1860, was observed to pass the guard-room drunk at half-past twelve in the day. He was at once confined; and when looked at by the sergeant of the guard at half-past nine p.m., he was not remarked beyond any of the other prisoners. At half-past five on the following morning, one of the other prisoners (it was quite dark) hearing a man blowing hard, called the sergeant of the guard, who had the man at once carried to my quarters. I sent him on to the hospital, and followed close after him. On his being laid on a bed in hospital, the following were his symptoms:

"Six a.m.—He lay on his back insensible; breathing stertorous; skin cold as death; contracted pupils; glassy, expressionless eye; frothing at the mouth; teeth rigidly clenched; he snapped the wooden mouthpiece of the stomach-pump in two as I tried to introduce the latter; pulse very slow and full; heart beats ditto, with a strong laboured action; arms and legs, on being raised, fell dead on the bed back again.

"*Treatment.*—Cold affusion; tried, but failed, to introduce the stomach-pump; three emetics of sulphate of zinc, and one of sulphate of copper, given at quick intervals. Three purgative enemata, which brought away no solid matter; turpentine frictions; blistered with blistering collodion in præcordial, temporal, and epigastric regions, in nuchæ and calves of legs; hot bricks to soles of feet; hot bottles to axillæ and to inner side of thighs; warm bedclothes. He lay perfectly insensible, notwithstanding the above treatment, until half-past eleven a.m., when he began to vomit a dark-green coloured fluid, smelling strongly of rum, the hospital orderly said. What I saw was inodorous. The vomiting and retching continued one hour. He then got roused and restless; complained of pain in the blistered parts; pupils became dilated; natural temperature returned, and he complained of pain in the belly, which was uneasy under pressure. I directed hot fomentations to it, and ordered him a pint of beef-tea, which he took well. I left him at three o'clock p.m. in a fair way to recover, as I thought, and in charge of two fatigue-men. They, I learned, permitted him to get out of bed, and do as he liked, so soon as my back was turned, instead of not allowing him to move. I was called to him again at six p.m., and found him just dying. I was told that he got up to go to the night-chair, and on returning to bed he relapsed into coma.

"*Post-mortem.*—Body well nourished, muscular. Brain, some red effusion into ventricles, small in quantity, in other respects not remarkable. Lungs, left strongly adhering to its pleura costalis; adhesions partly soft and partly rigid; base of left lung so adherent to diaphragm, that on being torn away from the latter, part of it was left attached to it (I had never known the man complain of his chest); this lung floated in water, and was infiltrated with black fluid blood, like black-currant jelly; right lung in a similar condition at its inferior portions, but in a less intense degree, and it was not attached to its pleura; it also floated in water. Heart of normal size, muscular, firm; attached edges of aortic valves felt rigid. A small white speck on the lining membrane of the aorta immediately above them. Liver small, weight 2lb. 11 oz.; its external surface and its sections had a scammony colour, no nutmeg appearance. Stomach presented symptoms of chronic gastritis (he was reported to have been of intemperate habits). Large intestines contained some scammony-coloured fæces. Ilium of a scammony colour, and strongly adherent to peritoneum of right pubic region. About half a pint of muddy-looking fluid, smelling of turpentine, found in right pubic regions. Kidneys had a mottled appearance on section.

"No. 5.—Within the last month (June, 1860), a case of delirium tremens occurred in a young officer under twenty, a Creole. The remarkable features in it were his having relapsed three times, two of them due, in the opinion of the experienced physician who attended him, to the nurse having allowed him to drink a quantity of brandy. In the second relapse he had strabismus, which was first thought to be owing to a commencing softening of the brain, but which disappeared after the action of a mercurial purge that brought away a considerable quantity of dark-coloured discharges. The treatment consisted in ammonia, camphor and laudanum, beef-tea, &c.

"July 9th.—I visited this officer yesterday. He is quite recovered of the attack of delirium; but he cannot walk, he states, unless supported by two men. He feels numb pains from the hip down, and the soles of his feet tingle and burn as if they were on fire." He cannot stand on his legs—they feel so weak, he says.

"No. 6.—Very early in the morning of December 13th, 1859, I was sent for to go on board the Royal mail packet that plies between Jamaica and Belize, to see an officer who had come as a passenger from the former place. I found him in his berth in irons. It would seem he appeared, when sent on board four days previous, to be like any other passenger; but on arrival at Belize he became so violent that at night he jumped overboard, and had to be put in irons, as before stated. It was told to me by one of the passengers, previous to this officer leaving the ship (which there was some difficulty in getting him to do) for the barracks, that his habits during the voyage were temperate (he took a stiffish glass of brandy-and-water, however, in my presence before he left). During the day he walked about, and talked sensibly upon most subjects. He complained of being watched, which was the fact. Thinking it highly probable he would become violent at night, I took the precaution to have four steady, athletic soldiers to watch him. It was well I did, as he became quite violent during the night, thought to jump out of the window, and maintained an 'up-and-down' struggle with the men for several hours during the night, trying to break open the door of his bedroom, which he nearly succeeded in doing. He was a very powerful, athletic man, upwards of six feet in height, and was nearly a match for the four men. His illness was attributed to the loss of his wife, who had died of yellow fever at Jamaica a few weeks previous, to whom he had been nine years married, had two children, and was reported as having been much attached to her. His face, however, bore the marks of chronic dissipation. Tartar emetic and opium in camphor mixture, in the proportions recommended by Graves, cured him completely in two days. I could learn nothing of his previous history, except that he had been fifteen years in the army. He appeared about thirty years old, but probably might not have been more than twenty-five, and had served some years in India. This case is introduced as furnishing a good example of the type of delirium tremens, which is generally best treated with tartar emetic and opium."

CASE OF ANEURISM BY COMPRESSION.

Dr Dennecé communicated a case of aneurism of the brachial artery cured after compression continued two hours and a half.

The patient was a vine-dresser, aged fifty-two, who presented at the upper third of the arm a tumour of the size of a walnut, which had acquired this magnitude in the space of two years and a half. The swelling was the seat of throbbing, expansion, fremitus, souffle, &c.

M. Dennecé applied instrumental pressure with an apparatus originally contrived for the femoral artery, which he adapted to the present case. The patient, being in great pain, removed the pressure after two hours and a half. The throbbing had much decreased within the aneurism, and next morning was found to have entirely ceased. In the evening it returned feebly, and J. L. Petit's compressor was resorted to for a quarter of an hour, and subsequently several times for a few minutes only, as the man could not bear a longer application.

One month after the patient had left the hospital, the tumour was hard and presented no throbbing. Above the swelling, the artery pulsated vigorously; the pulse at the bend of the elbow and at the wrist was weak, but more distinct than formerly; some pain was still complained of at the wrist, and also some degree of numbness in the middle finger.

In this interesting case the shortness of the time required for the obliteration of the aneurism is truly remarkable. In the most successful instances on record of the application of the method, pressure was continued for seven and a half, eleven, and twelve hours.—'Journal of Practical Medicine and Surgery.'

CHLORIDE OF ZINC MOULDED INTO STICKS FOR THE PURPOSE OF CAUTERIZATION.

Soften gutta-percha in boiling alcohol, and incorporate it with finely-pulverized chloride of lime in a warm porcelain mortar, taking equal parts of each. Then roll rapidly on a porphyry slab, to the diameter of a quill, and divide in fragments, each of which shall be pointed at one end. Keep these in a wide-mouthed bottle in powdered lime. These sticks remain perfectly hard, are easily handled, cauterize with great regularity, and act as a sponge through which the chloride will slowly exude, becoming liquid by the action of the air and the skin.—'Lancet.'

NOTICE.

The MEDICAL CIRCULAR is published every TUESDAY morning for WEDNESDAY. Price, Unstamped, 5d.; Stamped, 6d. A Stamped Copy sent regularly, per post, for Twelve months, for 19s. 6d. Post-office Orders should be drawn in favour of THOMAS ROLFE, 20 King William street, Strand, and made payable at Charing cross.

N.B — The MEDICAL CIRCULAR is duly registered for transmission to the Colonies.

THE MEDICAL CIRCULAR.

WEDNESDAY, AUGUST 29, 1860.

RECENT CASES OF ANTIMONIAL POISONING.

The question has been often raised, whether the publication of the details of trials for poisoning be beneficial or pernicious to the community. It has been frequently urged, that Editors of lay papers should be advised to refrain from the publication of such particulars, as they suggest to evilly-disposed persons the most successful means of accomplishing their object with the least probability of detection. We fear that any attempt to suppress that kind of information would be viewed as so important an interference with the liberty of the press and with the right claimed by the public to the most complete publicity of all things that transpire in our Courts of Law, that it would be impossible to give it effect. On the other hand, the danger of not telling enough, and of conveying a knowledge of the bane without also conveying the warning that attends the publication of the means of detection, seems to have induced the conductors of the press to dilate upon all such portions of the evidence with unusual minuteness and particularity.

It cannot be denied that this mode of furnishing malignant persons with a knowledge of the nature and uses of poisonous substances has led to the resort to these subtle agencies as a means of compassing murderous intentions. When bad men are made acquainted with the obscurity that sometimes cloaks the symptoms and effects of poisonous substances, and the difficulty with which they are occasionally distinguished from the characteristics and effects of ordinary disease, they are tempted to fly to these agents to gratify their satanic passions,—if, indeed, the horrible thought of murder may not be actually engendered in the mind by a consideration of the facility by which, with these means, it is believed to be accomplished. At any rate, the subject is a most important and painful one, and our only hope at present is that the science of diagnosis and the chemical means of detection will soon be made so certain and effectual that the escape of a poisoner from justice will be an impossibility. We may hope that the publication of the evidence will then deter rather than invite the attempts of the secret murderer.

For some time past there has been a propensity among murderers to resort to the use of antimony; and, unhappily, the effects of antimony upon the system are not so marked and positive as to enable Medical men to come to a definite conclusion in every case of alleged poisoning by this drug. Two cases have recently come under our notice: one occurred several weeks ago in the West of England, in which the Coroner's Jury brought in a verdict favourable to the supposition of the secret administration of antimony, and the other is now undergoing investigation at Liverpool.

In the first instance, an inquest was held on the body of Mrs Peters, whose case having been obscure to the Medical attendants, a suspicion of poisoning arose in their minds. Dr Garland of Yeovil, thereupon, on the 20th of June, sent the urine of the patient, and subsequently, on the 8th of July, some poisonous fluid taken from the cavity of the abdomen, together with the intestinal viscera, to Mr Herapath for the purpose of analysation. At the post-mortem examination, it was discovered that there was in the right lung a considerable deposit of tubercle, which was beginning to soften; slight deposit also in the left lung: in the abdomen, the mesenteric glands were found in an extensive condition of disease; the duodenum, liver, and colon were bound together by the results of inflammation; and at the lower edge of the large lobe of the liver there was an abscess which had burst, and its contents partially drained away. There were also two openings into the colon; and there were inflammatory patches in the stomach and intestines. Here, indeed, was disease enough to kill any unfortunate woman, even though she had been blessed with nine lives. The question was, how did this disease occur? Was it the result of antimonial poisoning? How does Mr Herapath answer these questions?

He deposed, "I submitted nearly all these parts (the solid parts) to analysis; testing some portions of the liver and of all the matters sent to me, but could not detect the presence of antimony, or other metallic or mineral irritant." With respect to the urine, however, he deposed that "it contained antimony in a small quantity, of which I produce a specimen as precipitated on copper by Reinsche's process." Here, then, there was a trace of antimony in the urine, although the body eighteen days afterwards contained none. These questions then arise upon the evidence:—Is it likely that antimony could have produced this particular form of disease? Is it likely that the extensive disease here present could have been induced by the small amount of antimony which must have been administered? Is it likely that if antimony had been administered in sufficient quantity to act deleteriously on the system, it could not be found in the diseased abdominal organs eighteen days after the last supposed dose? Or, if these questions be not probable, was it likely that small doses of antimony were clandestinely given for the purpose of accelerating the progress of the disease, though not of violently killing the woman? Or again, supposing Mr Herapath's analysis to be reliable, might not some of the drugs administered have contained sufficient antimony as an adulterant, to account for the minute trace discovered in the urine? In the evidence we have read, there is nothing specific stated as to the drugs administered, so that we are unable to form a conjecture upon this latter point.

We have alluded to this case because there seems to be considerable difference of opinion among the Medical gentlemen who attended the post-mortem examination as to the cause of death. Mr Walter, Dr Aldridge, and Dr Warry believed that the antimony had no relation to the disease; on the other hand, Dr Garland and Mr Thorpe, who attended the patient, and Mr Moore, seemed to think that the mischief had been induced by poison. The case is an instructive one, as it shows upon what slight evidence these cases sometimes depend. In our own judgment, there is not the slightest reason to believe that the more prominent symptoms and lesions were in any respect caused by the administration of antimony. It would be absurd to say that the tuberculosis was so caused; and where there is tuberculosis, you will have in the latter stages the other lesions described. Even the patchy character of the inflammation in the intestines is observable in advanced cases of mesenteric disease. There is not a shadow of doubt, therefore, in our mind that the suspicion of poisoning was quite gratuitous, and unfounded in any reasonable evidence. Still, there was the antimony—at least Mr Herepath says so; and was it administered with a felonious intention? Upon the evidence adduced, and without some proof of this drug having been purchased by or in the possession of some suspected person, we think it was exceedingly rash to press the opinion; and we do not think that the jury acted judiciously in sanctioning such a notion, and thereby keeping alive a feeling of distrust and odium against respectable persons. The case in a Medical point of view is abundantly clear, without the importation of the theory of poison.

The other case to which we adverted is that in which the man Winslow is concerned. As this case is now undergoing inquiry, it does not become us to express our opinion prematurely upon the evidence. We must observe, however, that it is of a very different character from that on which we have just commented; and we sincerely trust that the law will have its own.

SUMMARY OF THE WEEK.

THE ASSOCIATION 'JOURNAL.'

For some time past we have taken little interest in the affairs of the British Medical Association. There was a period when we endeavoured by modifying the Association to increase its usefulness, whilst at the same time its status was maintained: but finding efforts to effect any important improvement useless, we have left the Association to take care of itself; but it appears to be scarcely equal to the duty. At the late Annual Meeting, a vigorous debate was maintained, as usual, about the 'Journal.' All the members appeared to be ashamed of their own offspring. One gentleman thought it was ricketty, and required cod-liver oil and phosphorus—a combination of the oily and luminous; another, that it squinted, and didn't look great questions straight in the face; another, Dr Edward Smith, that it was without a character—which is a very severe remark to make about anything that has a soul in it, though it be ever so humble an one; another, Mr Southam, thought that it was altogether too weakly, and he desiderated an annual volume of 'Transactions' as a more respectable and healthy substitute; whilst a fifth considered that it was but too obvious that it was going off in a galloping consumption, and suggested that the Editor, who resides at Brompton, should take up his abode nearer to the office of the 'Journal,' that it might have more constant nursing. We cannot see the wisdom of this suggestion: our opinion is that it would be far better to send the 'Journal' to Brompton, where there is an excellent institution for the cure of consumptive patients, and where it might have the benefit of the advice of Drs Smith and Richardson. Dr Dayman of Southampton wrote a letter, in which he recommended that the 'Journal' should be placed in commission, and that the production of leading articles should be entrusted to twenty-six gentlemen, each of whom should write two every year. This was a novel and comprehensive suggestion; but it grievously disappointed Dr Thudichum, who thought it was only consistent with the dignity of the Society that the 'Journal' should be made the medium of the scientific intelligence of the whole world. We are only surprised that, after that, Sir Charles Hastings did not rise and propose that, as the Association was fond of big names and extensive purposes, it should be styled 'The Olympian Totally-terrestrial Œcumenical Association.' This phrase is indeed hardly equal to the ambition of the Society, which might very properly engage in the investigation of the phenomena of the celestial world, and adopt as a secondary title, 'or Fraternity of Eleusinian Spirit-Rappers.' Poor Dr Wynter looked very gloomy at these disheartening observations, and threatened resignation. As that, however, would be an awkward issue for all parties, especially for the six-and-twenty members of the Commission who would then be entrusted with the editorial duties, he recommended, as an alternative, a proposal made by Dr Seaton, that each subscriber *should pay the postage*, and thus save the Society 450*l.* a year—in other words, add this amount to the subscriptions. This was a most ingenious move: it was, moreover, the only practical remark that was made during the debate; so Dr Wynter deserves great credit for it. It is the easiest way of trapping 450*l.* a year that we have seen for a long time, and we can wish Dr Wynter no worse luck than that the subscribers may fall into the suggestion.

THE LIVERPOOL MURDERS.

Since we wrote our leading article, the investigation into the circumstances of the alleged murder of Ann Jones of Liverpool has terminated, and the prisoner, Thomes Winslow, has been declared "Not guilty." The poor woman died of cancer of the stomach; but inasmuch as considerable quantities of antimony were found in the urine and viscera, there can be no doubt that this drug was clandestinely administered by some unknown hand, and accelerated the death of the victim. It is ardently to be wished that the culprit may be discovered and punished.

COUNTY CORONERS.

The Bill for effecting certain changes in the mode of election of Coroners, and the payment of their officers by salary rather than fees, has passed both Houses of Parliament. It will, therefore, speedily become law. The present arrangement with respect to payment by fees will be allowed to continue until the conclusion of the year: in other respects the Bill will come into force as soon as it shall have received the sign-manual of the Queen.

SMITHFIELD MARKET ACT.

It is a source of much satisfaction to us to be able to state that this great sanitary measure has received the assent of the Crown, and that steps have already been taken preliminary to carrying out its provisions. As this has been a labour of love to us, we are correspondingly gratified by its successful termination. We were always convinced that opposition to the design would fail; and, more than that, we were determined that it should, for we knew that the object was both a necessary and salutary one.

DISMISSAL OF DR MAUNSELL, THE REGISTRAR FOR IRELAND.

Some time ago we pointed out the excess of expenditure incurred by the Irish Branch Council of Registration, and it seems that our observations prompted the Council to effect a reform. It was too much to expect that they would begin with themselves; but it is quite natural that they should begin with their Officers: so they ordered the dismissal of a Clerk. Dr Maunsell met this order with a tart reply; he did not think that the dismissal could be justified by the requirements of the law, and he asserted that it was a breach of the agreement with himself; and, in short, that whilst the amount payable for rent and salaries is only 430*l.*, "the sum appropriated to the six Members of this Branch Council for the year 1859 amounted to 926*l.* 2s." Bravo! Dr Maunsell! Here is a candidate for martyrdom, and it would be a pity if the ambition of his heart were not gratified. Accordingly, the Branch Council resolved:

"That having fully considered the proceedings of the last meeting of Council, in reference to Dr Maunsell's absence; also his letters of June 2 and July 20, inserted in Minutes of August 6; and further, his refusal at the meeting this day to remain in attendance,—the Council are reluctantly obliged to conclude that they cannot continue Dr Maunsell in the office of Registrar, and they therefore resolve that Dr Maunsell be and is hereby removed from the office of Registrar to this Council.

"That the salary of the Registrar and Secretary shall be and is hereby fixed at 200*l.* per annum.

"That an advertisement be inserted in the 'Saunders,' 'Freeman's Journal,' 'Daily Express,' and 'Irish Times,' for the appointment of a Registrar and Secretary at the salary of 200*l.* per annum; the election to take place on Friday, the 24th inst."

Honour before pelf at any time; and Dr Maunsell will go into retirement with the consolatory reflection that he has told the truth and suffered persecution for its sake. He must take to hoeing potatoes, like the Roman Cincinnatus, and find virtue its own reward. Seriously, we think the Branch Council rather shabby that they did not begin by setting the example of self-sacrifice.

SKETCHES OF EMINENT PHYSICIANS AND SURGEONS OF THE LAST CENTURY.

By JOSHUA BURGESS, M.D.

MEMOIR OF JOHN HUNTER, F.R.S.

(Continued from page 131.)

A further allusion to the discoveries which at this period, and for some years previously, had attracted so much attention, and provoked such eager discussions, is necessary. The avowed opponent of the Hunters, Jesse Foot, says, that "Haller had given the result of experimental injections of the testis in the 'Philosophical Transactions' before 1747, and Monro, sen., in the 'Medical Essays,' at the same time;" which experiments, he says, "were commenced before William Hunter had begun to teach anatomy—and before John had begun to learn." Haller,(a) the Monros, and William Hunter, were engaged making experiments upon the testis at the same time, and independently and unknown to each other, published their experiments. The dispute about the injection with quicksilver of the tubuli testis was between Dr William Hunter and Dr Alexander Monro, jun., of Edinburgh. William Hunter says upon this subject: "About the beginning of November, 1752, in the presence of Dr Galhie and others, I injected the vas deferens in the human body with mercury," . . . .

(a) Having carefully referred to the 'Philosophical Transactions' of the dates indicated, we find no trace of papers of this description communicated by Baron Haller.

"showed it next night at my public lecture." He further says, "Dr Alexander Monro published the same discovery in the 'Edinburgh Essays' . . . . and then in an Inaugural Thesis, in October, 1755, without acknowledgment."

Dr Hunter also, from the commencement of his lectures, eleven years before, taught and claimed the discovery in those lectures, that the lymphatics were the system of absorbent vessels, but did not publish this discovery. In 1755, Dr Alexander Monro, jun., "advanced this doctrine in a general way, and *first published it*, and, to his own satisfaction, established this claim;" and he further published this *quasi* discovery in his Thesis, in elegant Latin, at Berlin. He had, notwithstanding, attended W. Hunter's lectures, with Dr Reimarus, in 1755; and in that year, and 1856, Dr Reimarus candidly refers, in his own Thesis, published at Leyden, to the full exposition of Dr Hunter, of the lymphatic vessels, during that course. "Disregarding these circumcumstances, Dr Alexander Monro never referred to William Hunter's lectures, although he referred to every other author who had treated that subject." In 1755, immediately after, Munro published, and hinted an intention of treating it more fully on some future occasion. In face of all these conflicting circumstances, as we have above related, Dr Alexander Monro came to London, and attended William Hunter's lectures that season. In consequence of this inconsistent conduct, Dr William Hunter took the opportunity, in his public lecture, "blandly and in a conciliatory manner," to remind him of these proceedings.

The controversial tendencies of the Monros, father and sons, and the brothers Hunter, were well matched, and in weighing their claims it is difficult to adjust the balance rightly. The Monros were in stronger force, and, with equal *clanism* and polemical ability, displayed great *finesse* in resorting to early publication. The merit of being first in the field is due to the brothers Hunter: they relied upon announcement in public lecture as being sufficient, sought no further notoriety, and waited leisure and opportunity (as Dr Hunter, some years afterwards, quietly explained) for publication of these so-called discoveries. Discoveries in science propounded in public lecture in London must be considered sufficient to initiate and give paternity by such publication. Thus, with equal pugnacity and unequalled pertinacity, the brothers Hunter, by no means deterred by these unworthy pretensions and stealthy manœuvres, waged unmitigated warfare with the Monros for the triumph of the discovery of the *absorbent system in the lymphatic vessels*, and for the injection of the *tubuli testis*. Dr William Hunter says—"In reply to the challenge of Dr Alexander Monro to produce the testimony of some few of the number who saw the preparation in question in my anatomical course for the year 1752, he (I) published letters some years afterwards in the 'Medical Commentaries,' from six medical gentlemen residing at that time in London, who were present at the lectures."

We are constrained to say that these clever and eminent men never were more in their element or more self-complacent than in the midst of these wordy feuds. Dr William Hunter seemed to feel like one of the Greek warriors described by Homer, and certainly maintained a dignity and preserved a good temper that even Agamemnon, king of Argos, might have envied and imitated with advantage in his wordy war.

"When Greek meets Greek, then comes the tug of war."

Dr Adams, the devoted friend of the Hunters, says "the discovery of *hernia congenita* was Haller's; and though the experiments on absorption were conducted in a manner which completely showed Mr Hunter's sagacity and accuracy, yet the result was not entirely new." John Hunter, in speaking upon this subject, says, "This use of the absorbents I have been long able to demonstrate, and the first hints I received of it were in the waste of the sockets of the teeth, as also in the fangs of the shedding teeth....This I may assert, that whenever any solid part of our bodies undergoes a diminution, or is broken in upon in consequence of any disease, it is the absorbent system which does it....When it becomes necessary that some whole living part should be removed, it is evident that nature, in order to effect this, must not only confer a new activity, but must throw the parts to be absorbed into such a state as to yield to this operation. (*a*) This is the only animal power capable of producing such effects, and, like all other operations of the machine, arises from a stimulus or an irritation, all other methods of destruction being either mechanical or chemical: the first, by cutting instruments, as knives, saws, &c.; the second, by caustics, metallic salts, &c." Again he says, "The consequence of these two processes taking place together in bones is very singular. For the ulcerative process destroying the inside of a bone, while the ossifying makes an addition to the outside, the bone often increases to prodigious size, as in cases of *spinæ ventosæ*. But in the end the ulceration on the outside gets the better, and the matter makes its escape." (*b*) Again he concludes, "These uses I claim as my own discovery. I have taught them publicly since the year 1772."

Dr Foast Symonds, in his Life of Dr Hunter, gave the comparative merits to each. Mr Henry Watson had the first claim in the injection of the testis; Haller, to the discovery of the *hernia congenita*, to which discovery four anatomists laid claim—namely, Baron Haller, William and John Hunter, and Percival Pott. It is not a little remarkable that the last and William Hunter, the only controversialists in this particular instance, were the only two engaged who had no share in any part of the discovery. "Mr Pott never understood the subject, and blundered egregiously in the very terms he used, and in the later editions of his works omitted all he had written on the subject. Dr Hunter never appears without quoting his brother's notes. (*c*) The description of the situation of the testis in the fœtus, with its descent into the scrotum, was exclusively John Hunter's; and of all his labours none ever procured him fame so justly earned, and so universal with those who were best able to appreciate its merit." Ruysch, Nuck, Baron Haller, and M. Noguiez preferred earlier claims to having made experiments leading to the discovery of the function of absorption, to those of John and William Hunter. "Baron Haller and John Hunter each gave to the other an undisputed title to his respective claims." (*d*)

These incidents manifest the tone and temper of the brothers. The disputes in which they were involved, the tenacity and jealousy in asserting claims against each other, was an indispensable excitement, and seemed part of their nature. When they waived family feuds to sustain claims and pretensions against third parties, they incurred the censure of rivals and contemporaries, and their quarrels contributed to the professional gossip and scandal of the day. Nevertheless, science reaped benefit and advantage from their pertinacity and industry, by which they established an honourable fame, and laboured hard, and made great sacrifices creditable to the time and country in which they lived.

John Hunter now rose rapidly into notice, and had for some time formed an attachment to Miss Home, daughter of Surgeon Boyne Home, of Burgoyne's Regiment of Light Horse, a lady of most amiable character and accomplishments. This was an additional incentive: for although this lady's prudence forbade for the present their union, he increased his labours that he might have more leisure for the enjoyment of her society. His great expenses and numerous engagements delayed the marriage until 1771. The brother of Miss Home, afterwards Sir Everard Home, was at this time a boy at Westminster School, and John Hunter offered to bring him up to the Profession, to which his father consented. This afterwards brother-in-law was early trained in the family and under the eye of John Hunter, and necessarily arrived at considerable distinction, and had a baronetcy conferred upon him. It is a painful duty, in relating the history of human affairs, to have to record perpetration of dishonour and breach of trust under any aspect, even when the agent is sordid and servile; how much more when the delinquent has been trained under good circumstances and conditions—taught and confided in by the party whose trust he betrays—who had placed implicit reliance and unbounded dependence, shamefully betrayed by a Punic treachery! Living, as did Everard Home, in the house of John Hunter, or associating in it as familiarly as in his own, he enjoyed free access to the papers, manuscripts, and experiments upon which the labours of his life had been devoted. In short, Everard Home had been an amanuensis to his brother-in-law, and had assisted in copying and arranging his papers. This confidence was most sacrilegiously abused. He owed advancement in his profession, attaining as he afterwards did to its highest honours, under the auspices of John Hunter. Everard Home was appointed Sergeant-Surgeon to the King, was Vice-President of the Royal Society, served the office of President of the Royal College of Surgeons three times, was appointed by Government first Curator of the Hunterian Museum, filled innumerable distinguished and honourable offices, and was ultimately made a baronet, all of which honours may be traced to this connection. He was left executor and trustee, and had custody of John Hunter's manuscripts and papers, which were afterwards to be deposited in the Museum. During this time he was giving lectures upon Natural History, and publishing at different periods papers on various subjects of Physiology, as well as Natural History, mostly derived from these papers and manuscripts. The Council of the College of Surgeons and Trustees, appointed by Goverment, of the Hunterian Museum, had made repeated unsuccessful applications for the papers, documents, and manuscripts to be surrendered, to be deposited in the Museum. At length, upon the demand becoming peremptory, from long procrastination and continued delay in conforming with the conditions of the trust, the discovery of a most flagitious incendiarism could no longer be delayed. Sir Everard Home, Bart., the pupil, *protégé*, and brother-in-law, had burnt the manuscripts, papers, and documents of John Hunter. It is right thus early to name this nefarious transaction. In the historical record of the remaining incidents of John Hunter's life, Everard Home must be often named and reverted to in familiar connection and union. To guard this association, which under other circumstances would have conferred honour, from being prostituted for a moment, we expose the delinquency, to prevent even the passing existence of injustice. If it be any palliation, we freely relate that Everard Home was early inspired with a taste for physiological inquiries, and for Natural History. Even during his holidays from school he displayed this attachment, and was fascinated with the great talents and extent of research of John Hunter. How such perfidy could, with unhallowed step and brazen front, profane the sacred haunts of science, is incredible, when, if no higher principle existed, they ought to have been sanctified and protected from such invasion by ties of friendly intercourse and of near relationship. A brief history should be given of this affair, which may be comprised in a few words. It will expose a web of villany, almost if not quite unequalled in the history of literature. Everard Home and Dr Matthew Baillie were left trustees and executors of the will of John Hunter. After the purchase of the Museum by Government for the sum of 15,000*l.*, including everything collected therein—estate, preparations, specimens, manuscripts, and documents,—the Government transferred their custody to the Council of the College of Surgeons. It gave another 15,000*l.* for erection of a suitable building to receive them in Lincoln's Inn Fields, and afterwards nearly doubled the grant. They were wholly received into this building, and passed into the custody of the Council of the College, who appointed curators, with whose aid the Council intended to have prepared a descriptive catalogue of the whole Museum. Everard Home being one of the curators, took away from this custody "ten volumes of Minutes of Dissections, and many other valuable papers, without any previous permission of the trustees, with the avowed intention of employing them in preparing a catalogue, which he undertook to do gratuitously." Time passed, on and no catalogue was forthcoming. Repeated applications were made to Home for restoration. At length he turned round on the Council, maintained that no mention was made of them in Hunter's will, and that he had burnt them in accordance with the directors of his will. The falseness of this

(*c*) Adams' 'Memoirs of Life of John Hunter,' p. 32.
(*d*) Adams' 'Memoirs of John Hunter.'

averment is confirmed by his not having destroyed them, when in his hands, and before they were delivered up to the custody of the Council of the College, whose property they had now become. In explanation, it should be stated that Sir Everard Home contributed more papers to the Royal Society than any other single member of that distinguished body since its foundation.

(To be continued.)

HOSPITAL REPORTS.

ST GEORGE'S HOSPITAL.

AMPUTATION OF THIGH FOR DISEASED KNEE, AND AMPUTATION OF LEG FOR DISEASED ANKLE-JOINT—TUMOR TESTIS—NECROSIS OF TIBIA.—MR CÆSAR HAWKINS. FISTULA IN PERINÆO.—MR TATUM. FISTULA IN PERINÆO.—MR POLLOCK.

(JULY 26TH.)—AMPUTATION OF THIGH.

The patient, a woman about fifty years of age, under chloroform, had the thigh removed at the lower third by circular section. The disease had existed in the knee-joint about five years; latterly the soft parts became extensively diseased, and sinuses formed. The patient was a fleshy woman, and of full habit. Mr Cæsar Hawkins did not consider her a good subject for resection of joint. The extensive disease of soft parts at her age rendered excision an extremely hazardous operation.

Examination of Knee-joint.—The condyloid extremity of the femur found diseased and partly necrosed, cartilages destroyed, and synovial membrane inflamed and diseased. A large quantity of matter was found in the joint, and the tissues were extensively diseased.

(AUGUST 16TH.)—AMPUTATION OF THIGH.

Mr Hawkins performed amputation upon a patient, a young man about twenty years of age, who previously, rather more than two years since, had performed resection of knee-joint in one of the Metropolitan Hospitals, and was declared to be cured. It appears, notwithstanding, in this case, that the incisions and tissues had never closed, or a healthy process taken place. According to the history of this case, about five years since the man had been admitted a patient at St George's Hospital for diseased knee, found relief, and was sent to Margate to restore his health. At that time the synovial membrane was not diseased, but ligaments were beginning to be altered. He applied again, after resection of knee-joint, to a metropolitan hospital, about eighteen months since. At that time a large suppurating abscess was formed, communicating with knee-joint, bones found diseased through sinuses communicating with them. Circular incision under chloroform was performed by Mr Hawkins. Careful examination of joint, and a preparation of diseased structures will be made for the museum. A report of the conditions of the joint shall be given on a future occasion. The patient was a bad subject, worn down by long-continued suffering. A careful examination was made of this leg, removed by amputation, after a former operation of excision had been performed. The dissection discovered only a very partial union to have taken place between the tibia and femur. The latitude of motion it gave could have been but very limited. No union or junction had taken place in the popliteal region. Synovial membrane and ligaments were entirely destroyed, except a small portion of Winslow's ligament. We are indebted to Mr Holmes, Curator of St George's Hospital Museum, for the above.

TUMOR TESTIS.

This was a case of injury of the testicle from a blow received upon it some years since: the testicle was greatly enlarged and indurated. Mr Cæsar Hawkins recommended operation for amputation of testicle, as the only mean of relief; an opinion which was supported by the other surgeons of the hospital. Mr Hawkins stated that the patient had been under mercurial treatment on two several occasions without benefit: the tumour had been tapped previous to the operation, when serous fluid came away. He was placed under chloroform during operation. On examination, the tumour was found to consist of hematoid cells containing serum and bloody fluid.

(AUGUST 16TH.)—NECROSIS OF TIBIA.

This was strumous disease of the shaft of the tibia. The patient, a very intelligent, healthy-looking boy, about twelve years of age, was placed under anæsthesia. The diseased bone was situated on the left leg; the integuments and soft parts on the lower portion of the cylinder of tibia being discoloured, thickened, and three sinuses communicating with the bone. The ankle-joint was free from disease. Mr Hawkins made a free incision from the lower to the upper sinus; exposed the bone, which was found to be denuded of periosteum, by dividing tissues around, and removed a portion of necrosed bone with bone-nippers and forceps.

Mr Hawkins also operated upon a woman about twenty-five years of age, for strabismus, in usual way.

FISTULA IN PERINÆO.

This injury to the urethra was produced by a kick received upon the perinæum many years since, destroying a portion of the urethra, which consequently became obliterated. It is well known that reproduction of urethra upon destruction by injury does not take place. Division of the urethra through the perinæum, in consequence, was decided on by Mr Tatum. No passage existing through the urethra, the urine of late passed from the bladder in very insufficient quantity, causing great irritation and suffering to the patient. Mr Tatum made a very cautious and free dissection in the raphæ of the perinæum, commencing at the base of scrotum. After great care in searching, he found the urethra, cut into it, divided the cicatrix or condensed structure forming the obstruction, and reached the bladder with flexible catheter. A quantity of fetid urine escaped. The usual method of securing flexible catheter in bladder was adopted.

FISTULA IN PERINÆO.—MR POLLOCK.

This patient, a man about forty years of age, had stricture of urethra for many years. A sinus had formed in perinæum immediately below the scrotum, from which urine had for a long time passed. On Mr Pollock making incision into the grooved staff, considerable cartilaginous structure had to be divided in reaching the urethra. The operation was done in the usual way, introducing and securing flexible catheter by bandage round the hips and thighs.

UNIVERSITY COLLEGE HOSPITAL.

AUGUST 1ST.

HARE-LIP—VARICOCELE—VIDAL'S OPERATION.—MR ERICHSEN.

HARE-LIP.

This was an unusual condition of malformation, and consequent deformity, in a child about six months old. The fissure, of extraordinary dimensions, exposed a chasm from loss of soft parts, and a portion of the intermaxillary bone; and there was a cartilaginous cleft projecting into the mouth. After operating in the usual way, Mr Erichsen broke down tissues composing the alveolar process, dividing very freely the frænum, and then with necrosis forceps smashed the malformed intermaxillary cartilaginous projecting cleft. One of the milk incisors was removed, which would prove an advantage, since its presence might have interfered in the healing process: the permanent incisor would arrive when wanted, in due season.

VARICOCELE—VIDAL'S OPERATION.

No surgical disease affords such a variety of modes of operation as varicocele, several of which have now become obsolete. By pressure of varicocele upon the spermatic vessels, innutrition and consequent atrophy of the testicle occurs. Mr Erichsen has performed Vidal's operation with great success of late. Formerly he used hare-lip pins and twisted sutures, separating the diseased veins first from the vas deferens. Mr Hilton of Guy's Hospital and Mr Partridge of King's College Hospital have performed a simple and effective cure by ligature and subcutaneous section in the following manner:—A needle armed with silk ligature passed through skin and superficial fascia of scrotum *behind* the enlarged veins, and in front of vas deferens, is then passed through the same opening through the superficial fascia, under the skin, *in front* of the enlarged vessels, carrying the other end of the ligature with it, and thus by tying the two ends producing strangulation of varicocele. Mr Hilton cured four consecutive cases by this treatment in a very short time. Mr Bowman of King's College has also performed a simple mode:—Two needles, an inch asunder, are passed under the varicose veins in front of vas deferens and artery, and a silk ligature is twisted over them as for hare-lip, sufficiently tight to occlude the veins and stop the circulation, but not to cut them. The tenotomy knife being then introduced, the veins are divided by a very small incision between the needles, a pad and compress being laid over all. This operation has given very satisfactory results under Mr Bowman's treatment. It is attended with no hæmorrhage, no suppuration, no decomposed clot causing mischief by absorption, and no phlebitis. The cure is quick, the lower needle being removed in two days, and the upper in four days. Mr Erichsen now gives preference to Vidal's operation.

The patient, a man about thirty years old, was operated upon under chloroform. Mr Erichsen introduced a strong silver pin behind the varicose veins, and in front of the vas deferens and artery, taking especial care to avoid and protect them by separating them from the veins, and passed the pin through the skin and tissues. He then pushed a silver wire through the integuments of the scrotum and superficial fascia in front of the tumour forming the varicocele, twisted the wire tightly over the pin, and thus obliterated the enlarged veins. The wire is twisted several times by turning round the pin between the forefinger and thumb, thus effectually strangling varicocele.

WESTMINSTER HOSPITAL.—AUG. 8TH.

REMOVAL OF FLESHY TUMOUR IN AXILLA—OPERATION FOR STRABISMUS — WUTZER'S OPERATION (MODIFIED) FOR THE CURE OF INGUINAL HERNIA.—MR HOLTHOUSE.

FLESHY TUMOUR IN AXILLA.

This patient, a tall, well-formed, active, and strong-looking woman, about thirty-five years of age, had for a long time been afflicted with strumous abscess over her bosom, breast, back, and axilla. She was completely covered with old scars and seams on these parts. Until they discharged, they assumed a dark copper-coloured appearance, and an elongated form. Mr Holthouse stated that there was no reason to suspect they proceeded from a syphilitic taint, but were strictly of a strumous character, and thought the preparations of iodine were strongly indicated in the treatment, and might be beneficially administered in this case. The tumour or exerescence in the axilla to be removed had all these characters, was of a reddish purple colour, and of about two inches in length, and certainly manifested very much of the character of condylomata, and caused great irritation and pain to the patient. The tumour was removed by an oval incision carried round its base, and thus dissected out.

STRABISMUS.

A young man, about twenty-five years of age, was operated upon in the usual way. Mr Holthouse dissected the sclerotica with more freedom than is usually practised, giving greater facility to dissect and divide tendons of rectus muscle.

OPERATION FOR CURE OF INGUINAL HERNIA.

The patient, a man about sixty years of age, had an oblique inguinal hernia of enormous dimensions, the hernial tumour reaching nearly to the knee. Mr Holthouse decided to operate by a modification of Wiitzer's operation From the depending condition of scrotum and great size of the canal, a very large plug was required, which was made for the occasion. The operation, under chloroform, was conducted by invagination in the usual manner. Mr Holthouse did not think, from the great size of the hernial sac, and the age of patient, that it was a suitable case for Wood's operation.

KING'S COLLEGE HOSPITAL.—AUG. 11TH.

VARICOSE VEINS — OBLITERATION OF VENA SAPHENA, BY TRANSFIXION WITH PINS AND AND LIGATURE—STRICTURE OF URETHRA REMOVED BY SUDDEN DILATATION—LITHOTRITY.—MR FERGUSSON.

VARICOSE VEINS.

In this case, a female patient about twenty years of age, Mr Fergusson transfixed the vena saphena at the superior and anterior aspect of the limb, by introducing a pin under, and then another over, the vein. Having thus transfixed the vein,

he adopted the following method :—A slip of lint about half an inch wide, and several inches in length, was wound round and under the pins, thus to give a firm bite to the silk ligature, afterwards to be applied, without endangering breach of tegument. A silk ligature was then applied several turns tight round the lint, and also under and round the pins, thus effectually strangling the vein.

Mr Lee also operated upon a case of varicose veins—a sailor from the Sailors' Home—in his usual way, by pins, ligature, and subcutaneous section. This man formed one more of the numerous sailors King's College has returned cured into her Majesty's service.

STRICTURE OF URETHRA—CURE BY SUDDEN DILATATION.

This patient, a man about thirty-five years of age, who had suffered from stricture of urethra more than five years, came into hospital about five weeks since. His urine dribbled away. Mr Fergusson described the case. He stated that the man had ague—it was so-called ague. He was seized with rigors, or cold all over him, shivering—a very common condition attending stricture of the urethra, especially on attempting to pass a bougie or catheter. The instrument used to effect sudden dilatation was invented by Mr Holt, of Westminster Hospital. It was catheter-shaped, but split into two halves, having a wire running along a groove in the bottom half. Mr Fergusson had great difficulty to pass a catheter through stricture, and it required considerable patience and time to effect this object; the resistance, he stated, being in the region of the triangular muscle. He then passed Mr Holt's instrument through the stricture. Having a series of tubes graduated in size, he passed the smallest size first down the groove in Holt's instrument, until it became fully dilated thereby. He then passed the next, and afterwards a still larger size. The passage of these tubes causes considerable pain by the dilatation of the stricture they effect. Mr Fergusson desisted upon the passage of the third-sized tube, in consequence of the great disturbance it caused. He said the modes of curing stricture are various. The old, slow dilatation by bougies gives a healthy action to, and induces absorption of, parts thickened in the passage of the urethra, and thus effects a radical cure. Mr Simpson's (of Edinburgh) is another method, by division: and this method of Mr Holt's, by quick dilatation, he said he highly approved. It sometimes brings on fever, and cannot be persisted in; but it is a good plan, and the instrument is an excellent invention.

LITHOTRITY.

The patient, a man between fifty and sixty years of age, applied at the hospital about two years since, on which occasion, upon sounding, the stone could not be found. He came again about a year and a half since, when the stone was found, and Mr Fergusson broke it, and brought it away, and the patient seemed to be cured. He came again last week. Upon sounding, the stone was easily found. Mr Fergusson used a new instrument, which he described as a scope, made of two blades. He further said, the construction of the blades is just opposite to that of the lithotrite. It is made with a channel, and expands at the end like a scope, so that when it opens, it receives bits of stone, crushes, breaks them between the blades, and brings them away in the scope, as was done on the present occasion.

MARINE SANITARIUM AT CULPEE.—Mr Kirwan, of the Army Medical Staff, has published a proposal for establishing a marine sanitarium at Culpee, composed of a fleet of first-class troopships. Culpee is on the left bank of the Hooghly, at the point where it widens out into an estuary. He is of opinion that invalid soldiers, if sent there, and allowed to enjoy sea-trips in the bay, would not require to be sent to England to the same extent as now. He suggests the fitting up of the Government pilot-brigs as floating sea-barracks. This would prevent the great mortality amongst invalids while waiting for an order for removal to England. Now that the comfort and efficiency of the European soldier is really a political question with the Indian Government, Mr Kirwan's intelligent suggestions on this subsystem on troop-ships generally, have a chance that some at least considered.—'Friend of India,' it is evid.

MEDICAL SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 26, 1860.

F. C. SKEY, Esq., President, in the Chair.

A paper, by Mr T. B. CURLING, F.R.S., was read, being an

INQUIRY INTO THE TREATMENT OF CONGENITAL IMPERFECTIONS OF THE RECTUM BY OPERATION,

Founded on an analysis of 100 cases, 9 of which occurred in the practice of the Author. With the view of ascertaining and estimating the results of the operations which have been resorted to in the different forms of congenital imperfections of the rectum, either for the preservation of life or its future comfort, and of assisting to establish the best modes of proceeding in these cases, the Author has collected and tabulated 100 cases in which operations have been performed by himself and other Surgeons. Of these cases, 68 were males and 32 females. He classes the congenital malformations of the rectum as follows: 1. Imperforate anus, the rectum being partially or wholly deficient. Of this form the table furnishes 26 instances, 21 male, and 5 females. 2. Anus opening into a *cul-de-sac*, the rectum being partially or wholly deficient. Of this the table includes 31 cases, 17 males and 14 females. 3. Imperforate anus in the male, the rectum being partially or wholly deficient, and communicating with the urethra or neck of the bladder. Of this the table contains 26 cases. 4. Imperforate anus in the female, the rectum being partially deficient, and communicating with the vagina. Of this the table furnishes 11 cases. 5. Imperforate anus, the rectum being partially deficient, and opening externally, in an abnormal situation, by a narrow outlet. Of this form the table contains 6 cases. A few other congenital deviations have been observed, but they are of a very rare occurrence, and the five forms enumerated above are alone included in the table. The Author briefly relates a case of fæcal fistula, passing from the back of the sacrum to the rectum, which fell under his own observation. After briefly reviewing the causes of these malformations, and showing that though in most instances consequent on an arrest of development, they sometimes result from a pathological change due probably to inflammation occurring during intra-uterine life, the Author notices the relations of the peritoeneum to the bowel in the different forms of atresia, as having an important bearing on the operations performed in the perineal region, and states that in several instances in the table the fatal result was due to the opening made in the serous sac. He also calls attention to an imperfect development of the pelvis in those cases in which the rectum is wholly deficient. 1. The 26 cases in the table of the first form furnish the following results:—In 14 cases the gut was opened in the anal region, and in 12 the operator failed to reach it. Of the former, 9 ended fatally and 5 proved successful. Of the 12 cases in which the gut was not reached, 2 ended fatally without anything further being done. In 7, colotomy was performed in the groin; 1 only proved fatal. In 3, the colon was opened in the lumbar region; 1 recovered and 2 died. The Author gives some particulars of the 5 successful cases, and notices that there is only 1 of complete success in which the rectum was wholly wanting. In 3 of the cases in which the bowel was simply incised, more or less difficulty was experienced afterwards in maintaining a free passage for the fæces, but in 2 of the cases subsequent contraction was prevented by drawing the bowel down to the anal region. 2. In 16 of the 31 cases of the second form the gut was reached and opened. In 11 the operator failed in finding it. Of the former, 6 were fatal and 10 recovered. Of the 11 cases in which the gut was not reached, 6 ended fatally without any further operation. In 2, colotomy was performed in the groin with a fatal result. In 3 instances the colon was opened in the loin; 2 were fatal, and 1 recovered. In 4 cases colotomy was performed without any previous subpubic operation; three times in the groin with successful results, and once in the loin with a fatal termination. In analysing the 10 cases of success after a subpubic operation, the Author shows that in several cases in which the septum was slight the passage was readily established; that in others, where a space of some extent intervened between the two ends of the bowel, great difficulty was experienced in preventing contraction, unless the bowel was drawn down and attached to the skin; and he gives the particulars of a case treated by himself in this way with complete success. 3. The Author adduces some cases of the third form, in which, the communication between the rectum and urethra being more free than usual, life has been preserved for many months, the fæces escaping entirely by the urethra, until the passage becoming at length blocked up, death has ensued. Of the 26 cases in the table, the gut was reached in 15; in 9, the operator failed to find it. Of the former, 9 recovered and 6 proved fatal. Of the 9 cases in which the gut was not reached, 7 ended fatally without any further operation. In 1, colotomy was performed in the groin; in the other, in the loin: both ended fatally. In 2 cases no attempt was made to reach the bowel from the perinæum, but the colon was opened in the loin. One did well, the other died. In 7 of the successful cases treated by incision, more or less difficulty was experienced afterwards in maintaining the passage. In the only case in which the bowel was drawn down and secured to the skin, no contraction took place, and the boy was well and thriving at five years of age. After the establishment of a passage at the anus, the escape of fæces by the urethra did not always cease, and several instances are given in which serious inconveniences resulted from non-closure of the abnormal communication. 4. The Author, after alluding to instances of persons born with imperforate anus, the rectum opening into the vagina, who have passed through life submitting to the annoyances consequent upon it, states that the recto-vaginal communication is not always sufficient, and that obstinate constipation sometimes ensues. As the rectum descends low in the pelvis in this form, the operator cannot well fail to reach the bowel. In all the 11 instances in the table, the gut was opened, and only 1 ended fatally, from over-distension of the rectum, consequent on the operation having been delayed too long; 8 of the 10 remaining cases are reported as successful, and 2 as unsuccessful, owing to the tendency to contraction and neglect by the parents of the means recommended to maintain the passage. In one of the successful cases the bowel was drawn down and secured to the skin. The Author gives the particulars of two cases, which came under his notice, one successful, the other unsuccessful. In this malformation the establishment of a new passage at the natural site is not all that is required. We have also to obtain the closure of the abnormal communication of the vagina. A case in which this opening is reported to have closed spontaneously is the only one of complete success in the table. The Author is unacquainted with a single case in which, after the formation of an artificial anus, a successful operation has been performed for the closure of the recto-vaginal aperture. 5. Of the fifth form there are 6 cases in the table—4 males and 2 females. In the males the abnormal outlet was in the perinæum, just behind the scrotum, in 2; in 1 in the scrotal raphe, and in 1 anterior to the scrotum. In the females the opening was in the perinæum, close to the vagina, or at the posterior commissure of the vulva. In all the cases the vent was insufficient, and defecation more or less difficult. In this form, as in the last, the rectum can be easily reached, and it was opened in all six cases. Two different operations have been practised to remedy this imperfection:—1, the enlargement of the original outlet, which was done in two instances; and 2, the establishment of a new anus at the natural site, which was performed in the four other cases. The Author, after giving a detailed account of one of the cases in which he had recourse to the latter operation, contrasts the advantages of the two methods. In cases of imperforate anus, in which a passage is successfully established, the retentive functions of the bowel generally exist in sufficient force. Satisfactory evidence on this point is furnished by several of the cases in the table, and the existence of an external sphincter has been frequently recognised in dissection. The Author, after noticing that in cases of imperforation unremedied by operation, death is sometimes caused by extreme distension and rupture of the colon or the terminal pouch, remarks,

that the most common causes of death after operation are peritonitis and diffuse inflammation of the areolar tissue. The former is generally produced by a wound of the serous membrane, the latter by the passage of fæcal matter through the tissues of the pelvis, both being chiefly due to faulty methods of operating. He condemns the use of a trocar as a most unsafe instrument, and advocates the plan of drawing down the bowel and attaching it by sutures to the margins of the wound in the skin, an operation first performed by Amussat in 1835, and since described and recommended by Dieffenbach. The important advantage obtained by it is the securing a lining of mucous membrane for the passage traversed by the fæces. By this means we guard, not only against the tendency to contraction, with its consequent miseries and dangers, but also avoid the early risks of inflammation and fæcal absorption. In some instances troubles in defecation have continued after a sufficient passage for the fæces has been fully established, owing to an organic change in the bowel, consequent upon an obstruction of long continuance, subsisting after removal of the cause. The Author gives an account of some dissections in which the muscular coat of the rectum was found remarkably hypertrophied and its mucous follicles enlarged, and states that when the vent for the fæces has long remained insufficient, and the bowel has undergone these changes, its expulsive functions become seriously impaired and weakened, and the infant consequently suffers in the same way as adults labouring under stricture of the rectum. Having investigated the results of the operations performed in the perinæum, the Author proceeds to inquire into the degree of success which has followed the operations for opening the colon in the groin and in the loin, to ascertain the inconveniences consequent upon an anus in these regions, and to estimate the comparative value of the two operations. Colotomy was performed in twenty-one of the cases in the table—in fourteen by the inguinal operation, and in seven by the lumbar. In nine of the former an unsuccessful attempt had been made to reach the gut from the perinæum—four proved fatal, and five recovered. Of five cases in which no previous operation had been performed, one only proved fatal, and four recovered. Of the nine recoveries after inguinal colotomy, one survived only a month, two died of cholera within fourteen months, and a fourth was doing well at seventeen months; a fifth survived three years, and a sixth was doing well at thirteen years of age. M. Rochard has recently given an authentic report of the remaining three. One died at the age of forty-three; the two others are alive and well—one at forty-six years of age, the other at forty-three. Of the seven cases in which colotomy was performed in the left loin, attempts had previously been made to open the bowel from the perinæum in five, of which three were fatal. In another fatal case an attempt was made after the lumbar operation. The Author relates the particulars of a case operated on by himself, in which death was caused by injuries inflicted in the perineal operation before the infant came under his care. Of the two recoveries after lumbar colotomy, one infant lived to the age of seven years, and of the other there was no report more recent than seven weeks, and the child is supposed not to have long survived. The Author considers the two operations in reference chiefly to three questions—the difficulties of the operation, its dangers, and the condition and convenience of the artificial anus. The operation is admitted to be one of greater difficulty in the loin than in the groin; and after remarking on some of the causes of this, the Author notices the irregularities in the disposition of the colon, which render it impossible to open the bowel in the left loin without wounding the peritoneum, and which prevent the operator finding the colon in the left groin. The Author practised both operations on the bodies of twenty infants, and in two he was unable to open the colon in the left groin, in consequence of the colon making a sharp curve and passing over to the right side before reaching the pelvis. In six subjects lumbar colotomy was impossible without opening the peritoneum, owing to the colon being attached by a distinct mesentery and being loose in the abdomen. This serious impediment once occurred to the Author in performing lumbar colotomy in a case of imperforate anus. In respect to the dangers of the two operations, the results of the cases in the table are much in favour of colotomy in the groin. The Author quotes the description given by Rochard of the condition of the anus in the groin in two patients who had been operated on many years previously. Both were in good health, and suffered very little inconvenience. One had married and borne children. In all the patients observed by Rochard, prolapsus had taken place from the lower part of the bowel, but it was easily restrained. The Author also gives a particular description of a case, which has recently come under his own notice, of an artificial anus in the loin in a boy eight years of age, born with an imperforate anus, the rectum opening into the urethra. The anus was sufficient, but fæces escaped occasionally into the lower part of the bowel and caused difficulty in micturition. To obviate this difficulty, he had suggested the lodgment of a sponge-plug in the lower opening. The Author sees very little to justify a preference for either operation on the ground of the position of the anus; but the greater difficulties and dangers of lumbar colotomy would induce him in future to select the inguinal operation. The Author controverts the views recently advanced by Nuguier in favour of the performance of colotomy in the right groin in preference to the left, and shows by several examinations of infant subjects that the passage of the colon from the left iliac fossa to the right fossa is not so constant as he states. The Author, in conclusion, gives particular directions for conducting the operative treatment of imperfections of the rectum based on the results of this inquiry.

QUESTIONS FOR CANDIDATES FOR ASSISTANT-SURGEON IN THE ARMY.

AUGUST 13TH AND 14TH.

ANATOMY AND PHYSIOLOGY.

MR BUSK.

1. Describe the general characters of the ribs, and the peculiarities by which certain ribs are distinguished. Enumerate the muscles engaged in their elevation and depression.

2. Give a description of the cæcum and the ileo-colic valve; and state the difference in point of structure between the large and small intestines.

3. Describe, in the order in which they occur, the parts brought into view in exposing the anterior surface of the anterior scalenus muscle.

4. Describe the several parts brought into view in dissecting and removing the short muscles of the thumb and abductor indicis.

5. Give the physical and chemical characters of yellow elastic tissue, and notice the principal situations in which it exists in the human body.

6. Mention the circumstances which increase or diminish the amount of carbonic acid exhaled by animals.

SURGERY.

MR PAGET.

1. Enumerate not less than five kinds of wounds which you would *not* attempt to heal by the first intention; and state how you would treat each of them.

2. Describe the most frequent appearances, after death, of enlargement of the middle lobe of the prostate gland; and the symptoms by which that condition may be known, or suspected, during life.

3. Describe fully the proper treatment of a perinæum recently and completely ruptured during parturition.

4. What are the conditions on which secondary hæmorrhages after amputation depend, and what are the best modes of treating them?

5. Write Latin prescriptions for the following medicines for hospital use—namely, colocynth and calomel pills; jalap and calomel pills; compound senna draught; zinc lotion; hydrochloric acid gargle.

6. Describe the several forms of hydrocele connected with the testicle and spermatic cord, including those that occur in infancy, and mentioning particularly the characters of the fluids contained in them.

7. Describe the usual symptoms and progress of an ordinary case of cancer of the rectum. Under what circumstances, in the course of such a case, would you think it proper to open the colon?

MEDICINE.

DR PARKES.

1. What are the causes of anasarca? How is the effusion produced in each case, and how would you treat the principal forms?

2. Describe the appearances seen after death in the abdomen in the following diseases:—Typhoid fever; phthisis, with intestinal complications; dysentery.

3. What are the physical signs of the following diseases?—1. Pleurisy on the right side, with great effusion. 2. Obsolete pleurisy on the left side, with great contraction. 3. Cancer, commencing in the mediastinum, and infiltrating the whole of the upper lobe of the right lung. 4. Extensive tuberculosis and cavities throughout the left lung. 5. Great enlargement of the bronchial glands in a child.

4. Describe the symptoms produced by the passage of a renal calculus. What is the composition of the principal calculi? How would you treat a case of presumed calculous pyelitis?

5. What are the chief diseases to be watched for in the first week after delivery? Give their symptoms and treatment.

6. What are the preparations of mercury in the Pharmacopœia? How would you test for mercury in a complex fluid? What are the chief symptoms and the measures to be adopted in chronic poisoning from mercury?

NATURAL HISTORY, &c.

DR HOOKER.

Answer five or more of the following questions:—

1. What is meant by the respiration of plants, and how is it effected?

2. Give the botanical characters of the natural orders Labiatæ, Valerianeæ, and Solaneæ, and mention the medical plants they contain.

3. Contrast the reproductive systems in phanerogamous and cryptogamous plants.

4. By what characters are the orders of Dicotyledons grouped into four divisions, and of Monocotyledons into three?

5. What are the kinds of aloes used in medicine, how are they distinguished, and where do they come from?

6. To what constituents are the nutritious properties of wheaten bread due? Give their chemical composition, and explain the changes they respectively undergo during the operation of mastication and digestion.

7. Describe the nature and products of acetous and vinous fermentations.

8. Give the dental formula and peculiarities of the alimentary canal in ruminants.

9. Describe the structure and mode of development of a bird's feather.

10. Indicate the parts of the alimentary canal in which the different intestinal entozoa are chiefly met with.

11. Give the chemical composition of sea-water, and contrast hard and soft waters.

12. Define tersely the terms—etiolate, diluent, demulcent, viscid, plastic, elastic, dense, transparent, and translucent.

QUEEN'S MEDICAL COLLEGE, BIRMINGHAM.—At a Meeting of the Council of the Queen's College, it was resolved to complete the arrangements for the final conduct of the establishment. The following arrangements were made for the Medical Department:—The resident medical tutor to receive out of the warden's endowment 40*l.*; fees from twenty students, estimated at 80*l.*; and residence free. The west wing to be devoted entirely to the Medical Department. The resident professors to find their own board, and the resident students to be boarded by their respective professors. The non-resident professors to have the free use of the lecture-rooms, chemical laboratory, anatomical room, library, museums, &c. &c., and to receive, without deduction, the fees from the students whom their talents and industry may draw around them, but to be answerable for the coal and gas consumed in their department, also the wages of the porter employed by them, and all expenses incidental to the lectures—namely, prospectuses, advertisements, &c.

OUR NOTE BOOK.

ACCUMULATED MENSTRUAL FLUID.—IMPERFORATE UTERUS, WITH DEFECTIVE VAGINA.

Martha Smith, æt. twenty-three years, admitted into the Aylesbury Infirmary, May 2nd, 1859, under the care of Mr Hooper. Light hair, fair, and healthy complexion. With the exception of fever three years ago, her general health had been good. When she had attained her seventeenth year, she states she observed a slight appearance of menstruation; but since then there has not been any recurrence of it, though at irregular intervals she has had pain in the lower part of her back and hips.

About six months prior to admission, she observed that the left and lower part of her abdomen had become enlarged; the pains also, to which allusion has been made, were much aggravated, and she occasionally experienced difficulty in micturition.

The abdomen, as high as the umbilicus, is found enlarged and hard, the enlargement extending higher on the left side; it is not tender upon pressure.

Upon separating the vulva, a tumour is visible a short distance within its lips; it is elastic, adherent throughout its whole circumference, so that scarcely any trace of vagina is discernible, nor can any os uteri be detected.

Rotation of tumour in hypogastric region influences the tumour just within the vulva, clearly indicating its uterine character.

On May 8th a puncture was made into the elastic tumour with a trochar, and a dark fluid of a chocolate colour, inodorous, slightly coagulable, and of the consistence of treacle, amounting to 40 oz., was evacuated. Upon introducing the finger into the aperture, after the expulsion of that fluid, it passed directly into the dilated cavity of the uterus, the fundus of which could not be felt; its interior was smooth anteriorly, posteriorly corrugated, and it was evidently contracting.

The distance from the orifice to the fundus measured 6½ inches.

After the operation no hypogastric tumour could be felt.

14th.—There has been a considerable quantity of discharge since the operation, at first florid, subsequently assuming a pale colour; the cavity of the uterus has become contracted into a narrow passage measuring 4½ inches in length, and the aperture scarcely admits the point of the fingers.

Microscopical Examination.—The microscopical examination of this fluid afforded interesting results. It contained a vast number of the large compound cell-like bodies, which are so common in the blood of the spleen, called "blood corpuscle-holding cells." Such bodies are not unfrequently detected in blood which has remained for some time in contact with living tissues, as in cerebral hæmorrhage, extravasations of blood into cavities or into cysts, &c. The bodies in question are not in fact cells, but mere collections of blood corpuscles which assume more or less a spherical form. There is no cell-wall on the exterior of the mass, but the viscid material which causes them to cohere fills up the intervals between them, and thus the outline of the mass appears smooth, and even an outline like that of a cell-wall is produced. In this specimen of retained menstrual fluid, were observed masses of every size and form; and amongst them were numerous altered and partially disintegrated blood-discs, and much dark-brown granular matter, consisting, no doubt, of altered colouring matter of the blood.

The chemical composition of the fluid is shown in the following analysis:

Water		792·00
Solid matter		208·00
Soluble in water	Insoluble in alcohol	3·18
	Soluble in alchhol	3·78
Albumen and blood corpuscles		182·44
Fatty matter		2·80
Alkaline salts		6·24
Earthy salts		9·56

—'Archives of Medicine.'

CONSOLATION FOR DRUNKARDS.

Dr Smirnoff states that he has become convinced by repeated trials that the *Asarum Europæum* well deserves the reputation it has obtained in Russia of being an excellent remedy for the effects of drinking. The influence of a continuous abuse of alcoholic drinks is first exerted locally, but afterwards dyspepsia is produced; and the nutrition and functions of the entire economy, especially of the central portions of the nervous system, becoming interfered with, the blood itself being loaded with an injurious foreign material, the *dyscrasia potatorum* is at last completely established. The asarum fulfils various indications, acting beneficially on the alimentary canal in those cases in which the digestive powers are so much at fault. Its aromatic principle confers upon it a stomachic power, and regulates the condition of the intestinal disharges, producing vomiting and purging when given in large doses. Its most beneficial action, however, is manifested on the defective appetite, and by its counteracting the invincible longing for alcohol. The horrible sensations with which the drinker awakes in the morning, and which impel him to seek temporary and delusive relief from renewed libations, are much blunted and mitigated by means of a glass of strong infusion of asarum and some other nervine—*e.g.* valerian. Its immediate effect is often to produce vomiting, and sometimes purging; but the painful sensations at the epigastrium undergo relief, and the appetite becomes invigorated. Persons who have been long habituated to alcoholic drinks cannot, however, have these suddenly suppressed with impunity; and in such cases the Author gives the asarum in brandy, applying at the same time a blister or an issue to the pit of the stomach. By this means the normal activity of the stomach becomes excited, and the longing for alcohol diminished. The Author, however, cannot agree with those who would still allow a small quantity of spirits to habitual drinkers, even when the morbid desire for it has become appeased. The continuous use of a decoction of asarum, even when it does not succeed in extinguishing the desire for alcohol, always supports the powers of the patient; and it is remarkable in some cases, in which the individuals have been long accustomed to periodical intervals of drunkenness, ending in delirium tremens, how much longer those intervals will become, and how much less likely delirium tremens is to recur. The patients themselves are sometimes surprised at the comparative impunity with which they can continue their drinking. The Author prescribes three or four glasses a day of an infusion made with ℥iij. of asarum root, ℥j. of valerian root, and 3¼ of orange peel; but he does not state the quantity of water employed. In cases of drunkenness, another formula is composed of decoction of asarum (made by boiling from ℥ß to ℥j. of the root) ℥vj., tinct. of valerian ℥ij. to ℥iij., Sydenham's laudanum gtt xij., syrup of orange peel ℥ß. A tablespoonful of this is taken every two hours. He finds from two to five grains of bismuth taken four times a day a valuable adjunct. He has also found the following popular Russian remedy of service in cases of drunkenness:—R. Ammon. carb., 3½; aceti vini, lbj.; oxymel scill., 3½. Two tablespoonfuls every two hours.—'Med. Zeit. Russland' and 'Med. Times.'

ON THE RESORPTION OF PLEURITIC EXUDATIONS.

Professor Skoda says: The resorption of pleuritic exudations frequently takes place very slowly, because the capillary vessels in the sub-pleural connective tissue are obliterated. This may be the result of shrivelling and disappearance of the connective tissue newly formed from the exudation, as then, in consequence of the arrest of the metamorphosis of tissue between the blood and the exudation, endosmoes and exosmose cannot duly take place. It is not until after the lapse of months or years, when the fluid portion of the exudation has penetrated through the false membranes investing the pleura, that its resorption occurs. In the first case, internal medicines can, of course, avail nothing, as in them we possess no means of exciting the reformation of vessels. What has been said explains the action of iodine injected in exudations, inasmuch as, by exciting inflamnation, it causes the development of new vessels, and so induces the resorption of the effusion. But this view does not, perhaps, encourage us to the frequent employment of thoracentesis and subsequent injection of iodine; for this proceeding is by no means so safe as the corresponding operation for hydrocele. But, apart from that consideration, the injection of iodine or nitrate of silver into the pleural sac can answer no useful purpose; as, on the one hand, in consequence of the presence of the albuminous exudation, the caustic influence of these agents cannot reach the pleural sac, particularly as by the chemical combination which these substances form with the effusion, their power is altered and exhausted, so that the fluid must in the first instance be pumped out, which violent and sudden evacuation may be attended with evil consequences. But, on the other hand, in effusions of long standing, which have already attained to partial organization and shrivelling of the product of inflammation, the injection will be inefficacious, because the lung can now no longer fill the space previously occupied by the fluid exudation, especially as the investing false membranes must first be broken up by the lungs, which is not conceivable. But even if this should take place, a sudden evacuation could be followed by no favourable result, because necessarily there must be ruptures of the pleuritic adhesions and bursting of the compressed pulmonary parenchyme. Therefore, in a pleuritic effusion of long standing, it is only exceptionally that puncture is admissible, when the exudation is so considerable as to depress the diaphragm, to displace the mediastinum, and so to compress the lung that danger of suffocation supervenes. But how can the resorption of pleuritic exudations be induced? Experience shows that all those means which lower the pressure of the blood or augment the secretions, and therefore promote the separation of water from the blood, effect a diminution of the fluid effusion. Accordingly, venesections and diuretics may be indicated in cases of effusion; but these effects also occur spontaneously. In chronic exudations, which are already organized, such means will even be rather injurious, and the indication will be to employ remedies capable of dissolving solid exudations. Such remedies are iodine and mercury. The cautious employment of these means may therefore be adopted, and they are particularly suitable for external application. Professor Skoda has for some years employed these means experimentally, and has often seen pleuritic exudations rapidly diminish after the use of mercurial ointment, iodina ointments, iodide of glycerin, and black oxide of copper in the form of ointment. It is self-evident that in all chronic pleuritic effusions the diet must be good, in order as much as possible to counteract their injurious effects upon the system at large.—'Vierteljahrschrift für die praktische Heilkunde,' 1860, Band lxv. Analekten, p. 53.

ANCHYLOSIS OF THE INFERIOR MAXILLA CURED BY THE METHOD OF PROFESSOR RIZZOLI.

(From 'L'Sperimentale et Racoglitore Medico de Fano.')

The patient, who was named Louise Vaiola, and was about twenty-three years of age, appeared to be of a lymphatico-venous temperament, and had menstruated regularly for nearly eight years. A short time after the appearance of this function, she perceived that the left commissure of the lips was visibly drawn away from the same side, without, however, any cause being discoverable for the change. About the same time a slight but continuous pain made itself evident at the left posterior angle of the lower jaw, and went on increasing, assuming the lancinating character, and accompanied by tumefaction about the bone; the surrounding soft parts became red, swollen, and painful; and, in a word, all the symptoms of the formation of an abscess showed themselves. Without consulting any surgeon, the patient herself applied local fomentations, which probably hastened the formation of the pus, and which eventuated in the bursting of the abscess internally near the last molar tooth but one; immediately the pain, redness, and swelling disappeared as if by enchantment, and the only symptom which remained was a certain stiffness of the jaw, the movements of which became gradually more difficult, painful, and finally altogether impossible, and for eight years she remained in this miserable state.

On the 4th of December, 1858, the patient was admitted into an hospital. At this time the left cheek was more depressed than that of the opposite side, and an exploration being made along the horizontal ramus of the jaw, the fact was established of a loss of osseous substance near the posterior angle of the jaw. The finger when introduced inside the cheek was also stopped by strong adhesions of cicatricial tissue, and the teeth were to be found in their alveoli, all except the two upper incisors, the absence of which allowed of the introduction of some liquid nutriment.

It is not our intention to enter into the question of the cause of the disease, as that would lead us too far from our subject. It remains for us to describe the actual operation, as performed by the Author on the 12th of December.

The patient being seated, and her head supported against the breast of one assistant, while another drew down the lower jaw, the operator made an incision in the *cul-de-sac* which united the lip and gum of that side, exactly at the space which corresponds to the second and third molars: this incision divided not only the mucous membrane, but also the subjacent soft parts, so as to lay bare the lower bor-

der of the jaw; by this wound was then introduced the straight and blunt branch of the bone forceps, which embraced the internal border of the jaw, so that the cutting edge of the instrument was easily placed on the outside. A slight force only was necessary to completely divide the maxilla at one stroke, and thus restore to the jaw the motion which it had lost for eight years. The operation was not interrupted by any complication, either during or after its performance.

The following is a short report of the consequences of the operation :—

December 14th.—The girl is quiet; a slight hæmorrhage which broke out in the wound was quickly stopped by the insertion of a piece of lint steeped in Pagliari water. In the evening, fever and headache.

15th.—Wound painful; pulse nearly normal. In the evening, pulse febrile.

16th and 17th.—Improvement.

18th, 19th, and 20th.—Pain less severe. Tepid fomentations to the seat of the disease. To have a scammony purgative.

21st.—Pain more intense; deglutition difficult.

22nd.—Slight improvement; the separation of the jaws accomplished with some ease, and without much pain.

25th, 26th, and 27th.—Steady improvement; a piece of cork was introduced into the angle of the jaw, in order to keep the two parts separate.

28th.—A small abscess appeared at the left side of the chin, which was opened on the 8th of January. This was caused by the presence of some small fragments of bone which were necrosed and detached. The formation of the false joint, however, which was to render permanent the movements of the jaw, was somewhat delayed, and it was not till after the extraction of the two teeth next the fracture that the false joint was completely established, while during the greater part of the time hospital gangrene was present in the neighbouring wards.

The girl who was the subject of this proceeding is now quite cured: she is able to separate her jaws widely; to chew her food—to eat, drink, laugh, speak, as in the normal state, and will soon return to her family, among whom she is at present an object of wonder and delight.—'Presse Medicale Belge, and 'Dublin Medical Press.'

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

FRIDAY, AUGUST 17TH.

CASE OF MR GEORGE BULL.

The Earl of HARRINGTON moved for reports of the Coroner's inquest and Crown trial at Lewes, of George Bull, a surgeon, tried for the manslaughter of Sarah Anne Bull, his own mother, by an overdose of prussic acid administered by him when in a state of excitement and intoxication, and found guilty at the inquest, though above suspicion of bad intention, and acquitted by the Assize Court. The noble Earl read extracts from the evidence given before the Coroner and the Judge at the trial, with a view of showing that portions of it taken at the inquiry before the Coroner were not given at the Crown trial, and that the verdict of acquittal was therefore not to be justified.

The LORD CHANCELLOR said he knew nothing of the case himself; but the speech as well as the motion of the noble Earl was, in his opinion, greatly to be deprecated. A British subject had been properly tried and acquitted by a jury of his countrymen; and the noble Earl notwithstanding thought it consistent with his duty to call in question that verdict, and to impute guilt to the party charged. The man was tried before a judge and jury in the face of a number of persons, and was entitled to the verdict given in his favour. There never was a judge more devoted to his duty than Sir Alexander Cockburn, and inasmuch as this man had had a fair trial, and obtained an honourable acquittal, he thought it would not be well that the papers asked for should be produced, as the production might tend to the idea that there had not been a fair trial. It was quite clear that their lordships had no right to compel the production of the notes made by the judge at the trial for his own guidance.

Lord GRANVILLE, on the part of the Government, declined to accede to the motion.

The motion was negatived without a division.

TUESDAY, AUGUST 21ST.

COUNTY CORONERS BILL.

The Lords resolved not to insist on their amendments, with which the Commons had disagreed.

HOUSE OF COMMONS.

FRIDAY, AUGUST 17TH.

IRISH MILITIA SURGEONS.

In reply to Colonel Dunne and Mr O'Connell, Mr S. HERBERT stated that he had not yet been able to make any change in the position of militia surgeons. In Ireland their case seemed harder than it was in this country. Here the head-quarters were generally at some large town, where there was a good private practice to be got; but in Ireland the head-quarters were often in some insignificant place, which did not afford the militia surgeons the same advantages. If in another year he could do anything to improve their condition, he should be glad to do so.

SATURDAY, AUGUST 18TH.

On the vote of 2,500*l.* for the expenses of the inspection of burial-grounds, &c.,

Sir G. C. LEWIS explained that, under certain Acts of Parliament, the Government were directed to close burial-grounds, and also to interdict interments within churches; and in order to carry out the provisions of these Acts two inspectors were appointed, and their expenses constituted the sums mentioned in the vote before the committee.

Mr E. JAMES asked when these two gentlemen were appointed to perform these melancholy duties, as no other statement in reference to the vote had been made to the committee than that which they had just heard.

Sir G. C. LEWIS said that the inspectors were appointed in 1855.

The vote was agreed to.

It was proposed that a sum of 6,010*l.* should be voted for salaries and expenses of the office in London under the Local Government Act, in connection with the late Board of Health.

Mr WILLIAMS considered the establishment was perfectly useless.

Sir G. C. LEWIS defended the vote, and promised, if possible, to avoid the necessity of filling up an existing vacancy in this department.

The vote was agreed to.

The following votes were also agreed to :—2,721*l.* to defray the salaries and other expenses of the office of Inspectors of Lunatic Asylums in Ireland; 6,160*l.* to pay contingent expenses of the office of the Commissioners in Lunacy in England, and the salaries and expenses of the Board of Lunacy in Scotland; 36,400*l.* to pay salaries, contingent and other expenses, in the department of the General Register-office, England and Wales; 3,831*l.* to pay salaries, contingent and other expenses, in the department of the General Register-office, Dublin; 5,812*l.* to pay salaries, contingent and other expenses, in the department of the Registrar-General of Births, Deaths, &c., Scotland.

MONDAY, AUGUST 20TH.

MORTALITY OF THE 'TASMANIA.'

Mr WARRE wished to be informed by the Secretary for India of the result of the inquiry into the equipment and victualling of the ship *Tasmania*, which brought troops home from India some months ago.

Sir C. WOOD said, as the ship arrived in this country in a most melancholy state, he wrote by the mail to Calcutta, desiring that some inquiry should be made into the state in which it left Calcutta. The only answer he had received from Calcutta was that the inquiry had been instituted. He had not received the result of the inquiry.

Births, Marriages, and Deaths.

BIRTHS.

BIDDLE.—June 7, on board the troop ship 'Sevilla,' on her homeward passage from Calcutta, the wife of Assistant-Surgeon T. J. Biddle, 8th (the King's) Regiment, of a daughter.

GODFREY.—August 18, at Carlton House, Enfield, N., the wife of a Dr Benj. Godfrey, F.R.A.S., of a son.

HICKS.—August 18, at Old-street road, the wife of George Borlase Hicks, M.D., of a son.

JONES.—August 20, at Trebandy House, near Ross, Herefordshire, the wife of Edmund Jones, M.D., of a son.

LOE.—August 7, at Leeds, the wife of J. S. Loe, Esq., M.R.C.S., of a daughter.

MILLAR.—August 17, at Oak House, Enfield, the wife of Samuel Millar, M.D., of a son.

PLOWMAN.—August 13, at St Austell, Cornwall, the wife of W. Taunton Plowman, M.D., of a son.

TIBBITS.—August 17, at Warwick, the wife of John Tibbits, M.D., of a son.

MARRIAGES.

DAVIS.—LEWIS.—August 15, at St Mary's, West Brompton, Cresswell Davis, Esq., M.R.C.S., of Brompton, to Louisa Jane, fourth daughter of the late Richard Lewis, Esq., of Dawley, Salop.

ENGLISH.—MANDER.—August 16, at St John's, Hackney, Thomas English, M.D., to Jane, the only surviving daughter of J. G. Mander, Esq., of Albion square.

GRAHAM.—ELLIOTT.—August 16, at St Mary's, Islington, Thomas Hore Graham, Esq., M.R.C.S., of Lamberhurst, Kent, to Charlotte, eldest daughter of Robert William Elliott, Esq., of H.M.'s Inland Revenue Office, Somerset House.

KING.—GLYNES.—August 16, at St John's, South Hackney, Wm. Talbot King, Esq., M.R.C.S., of Thurloe place, Hackney road, to Lily, only child of the late George Glynes, Esq.

LAING.—GLENNIE.—August 9, in the Trinity Presbyterian Church, Church road West, Islington, John Laing, M.D., to Susanna, daughter of the late John Glennie, Esq., of Kingsland.

RAYNER.—LEA.—August 16, at St Michael's Church, Highgate, Thomas Rayner, Esq., M.R.C.S., of Birstal, Yorkshire, to Anne, eldest daughter of Thomas Lea, Esq., of Fitzroy park, Highgate.

DEATHS.

BUSH.—August 2, at his residence, 57 North Moore street, New York, Dr Ralph J. Bush, in his 80th year.

CLERE.—July 30, at Brooklyn, New York, Dr Edward Clere, aged 64.

COOLEY.—August 25, in Devonshire, Matilda Jane, second and beloved daughter of Mr Arnold J. Cooley, of Pimlico, in her 20th year.

DUMERIL.—Professor Duméril, the eminent French naturalist, has just died at the advanced age of 86

FOX.—August 10, at Wood lane, Falmouth, Samuel Tregelles Fox, M.R.C.S. Eng., L.S.A. Lond., aged 30.

GUTHRIE.—August 11, at Dunblane, James Guthrie, Surgeon R.N., L.R.C.S. Edin.

HAWKESWORTH.—August 16, of fatty degeneration of the heart, Charles Adolphus Hawkesworth of Burton-on-Trent, M.R.C.S. Eng., L.S.A. Lond., aged 48.

HAY.—August 18, at his residence, 2 Newgate street, City, James Hay, M.R.C.S. Eng., aged 70.

HEGEMAN.—August 2, at Orange, New Jersey, United States, America, Frederick Augustus Hegeman, Associate of the College of Pharmacy, New York, aged 39.

KENNEDY.—August 15, at Apledale Hall, Staffordshire, Anna Maria Kennedy, daughter of the late Hugh Alexander Kennedy, M.D., and sister of the late Sir Robert Hugh Kennedy, Commissary-General-in-Chief under the Duke of Wellington in the Peninsula.

MOLLOY.—July 16, of paralysis, at Malone, New York, Dr P. E. Molloy, aged 60.

TOONE.—July 11, at Salisbury, John Toone, M.R.C.S.E., aged 70. He was for forty-six years a resident in that city. He had formerly served as an Assistant-Surgeon in the Royal Navy.

WEBB.—July 31, at Brooklyn, Long Island, Dr Edwin Webb, jun., aged 21.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed the examination in the science and practice of Medicine, and received certificates to practise, on Thursday, August 16 :—John Erskine Chalmers, Hull; William Foster Giles, Cheltenham; T. Miles Hill, Clifton, Bristol; Emuel Downes Moult, Marple, near Stockport; Henry Williams, Framlingham; Charles J. Workman, Reading.—The following gentlemen also on the same day passed their first examination :—John Cooke, University College; William Soper, Guy's Hospital.

University of London.—The following is a list of candidates who passed the recent First M.B. examination :—

First Division—John Bayldon, University of Edinburgh ; John William Bell, Hull School of Medicine ; Palemon Best, University College ; Thomas Wemyss Bogg, University College ; Alexander Crum Brown, M.A. Edin., University of Edinburgh ; Arthur Wellesley Edis, Westminster Hospital ; Henry Stanley Gale, King's College ; Thomas Griffiths, University College ; John Harwood Hooper, St Thomas's Hospital ; John Talfourd Jones, University College ; Edmund Cornish King, University College ; Henry Thomas Lanchester, St Bartholomew's Hospital ; John Langton, St Bartholomew's Hospital ; Frederick Fawson Lee, St George's Hospital ; Henry Colley March, St Thomas's Hospital ; Frederic Marsdin, King's College ; Frederic Meggy, Guy's Hospital ; John Thomas Mercer, Guy's Hospital ; Richard May Miller, B.A., University College ; Thomas Morton, King's College ; Richard Orton, Royal College of Surgeons, Ireland ; Edward Parson, King's College ; William Powell, London Hospital ; Frederick Thomas Roberts, University College ; Thomas Starkey Smith, University College ; Edward Thomas Tibbits, University College ; Joseph Todd, Queen's College, Birmingham ; Forbes Watson, St Thomas's Hospital ; Thomas James Woodhouse, St Thomas's Hospital.

Second Division.—John Penning Baker, John Cooke, Richard Dawson, Athenodore de Nigri, Edward Mahoney, Wilmot Horton Trevor Power, B.A., all of University College.

Appointments.—M. Morel-Lavallée has been appointed to the Surgeonship made vacant at the Necker Hospital, Paris, by the death of M. Lenoir ; and M. Desormeaux, of the Lourcine, is appointed to the Cochin Hospital, in place of M. Morel-Lavallée.

Army Medical Service.—Names of successful candidates at the Competitive Examination for Commissions in the Army Medical Service, August 20 :—C. H. Y. Godwin, St Bartholomew's Hospital ; John Walters, M.B., King's College ; F. Gillespie, M.D., Cork ; A. A. Gore, M.D., Dublin ; T. Maunsell, Dublin ; G. F. White, University College ; F. R. Wilson, M.B., Dublin ; W. H. Jones, M.D., Cork ; N. Alcock, Dublin ; D. McG. Davidson, M.D., Glasgow ; R. E. Heath, M.D., Dublin and Belfast ; Robert Adams, M.D., Glasgow and Dublin ; R. C. Lever, London ; B. I. Jazdowski, M.B., Aberdeen ; James Thompson, Dublin ; C. S. Wills, Dublin ; R. B. Riordan, Dublin ; Samuel Hope, St Mary's Hospital ; Thomas Y. Baker, St Bartholomew's Hospital ; J. H. N. Bracken, Dublin ; P. Quinlan, Dublin ; Frank Pout, King's College ; C. P. Baxter, M.D., Dublin ; S. G. White, M.D., Edinburgh and Belfast ; Henry Lamb, Dublin ; H. O. Harvey, St George's Hospital ; E. B. Grant, M.B., Aberdeen ; W. R. Wall, Dublin ; T. P. Flynn, Dublin.

Sir Benjamin Brodie and the Irideotomists.—The Medical newsmonger of the 'Times,' who now and then comes to the rescue of ambitious Medical aëronauts, thus breaks the fall of one of them, we know not which :—"A paragraph having appeared in some newspapers on the state of Sir Benjamin Brodie's health, we are authorised to state that he has lately undergone an operation for the improvement of his sight, and that a satisfactory result is anticipated." The "operation," it appears, was the process called "Iridectomy," to which the Nestor of English Surgery was submitted on the 12th July last, and the "anticipated satisfactory result" is blindness of one eye and a *status quo* of the other. The disease, we learn, "had been regarded as *senile cataract ;*" then "the defective vision was ascribed to *glaucoma*," and now "the eye is *not* glaucomatous, and may be restored by extracting the cataract." We are sorry for all this for Sir Benjamin's sake, and somewhat abashed on account of Anglo-German ophthalmology ; but it is an ill wind that blows nobody good, and so London Eye Surgeons may be the better of the mishap.—'Dublin Medical Press.'

Circulation of the Blood.—The Academy of Medicine of Madrid has two questions for its prizes for 1860. One is the following :—"What share have Spanish Authors had in the Discovery of the Circulation of the blood ?"

Thomas Cotterill, Esq., a Birmingham *millionaire*, has left the following legacies to different local Medical charities :—the General Hospital, 1000*l.* ; Queen's Hospital, 1000*l.* ; Dispensary, 1000*l.* ; Deaf and Dumb Institution, 1000*l.* ; the Blind Asylum, 500*l.*

Criminal Lunatics.—In addition to the Act mentioned in 'The Lancet' last week respecting the Queen's prison, there was one passed on the 6th inst., under which her Majesty may appoint an Asylum in England for the custody and care of criminal lunatics. The Secretary of State is empowered to appoint a Council of Supervision and officers for such asylums, with rules for the treatment of the inmates. There is a provision in the Act by which the Secretary of State may permit a lunatic confined "to be absent upon trial for such period as he may think fit, or to permit any such person to be absent upon such conditions in all respects as to the Secretary of State shall seem fit." In the event of a person not returning, then he is to be retaken, as in case of an escape. The Commissioners in Lunacy are to visit the asylums provided or to be appropriated under this Act (23rd and 24th Victoria, cap. 75), and to report to the Secretary of State. Any superintendent, officer, servant, nurse, or other person employed in an asylum, who strikes, wounds, or ill-treats, or wilfully neglects any person confined therein, is to be guilty of a misdemeanour, and, on conviction, liable to fine and imprisonment, or to forfeit for every such offence, on a summary conviction, a sum not exceeding 20*l.*, nor less than 2*l.*

Lord Byron's Foot.—Models of the feet of Lord Byron have been this week deposited in the Museum of the Nottingham Naturalists' Society. They are described as about nine inches long, narrow, high at the instep, and generally of symmetrical shape. In an accompanying affirmation, it is stated that the deformed foot (the left) was not, as has been generally stated, a "nub" foot, but that it was formed symmetrically as the other, being, however, exactly an inch and a half shorter. The ankle was weak, and the foot turned outwards. To remedy this, it states that Lord Byron wore a very thin boot, tightly laced, under his stocking ; and in early life employed an iron, with a joint at the ankle, passing down the outside of the leg, and fastened to the sole of the shoe. The muscles of the calf were atrophied.

Distinguished Medical Men.—In the ranks of general literature and science, British Medicine is rich at the present time in representative men—Sir Benjamin Brodie, President of the Royal Society ; Livingstone, the pioneer of civilization in Central Africa ; Owen, the British Cuvier ; Darwin, the far-seeing, fact-compelling, naturalist ; Lever, the Irish novelist ; Sir James Kay Shuttleworth, the public educationist ; Sir Charles Nicholson, founder of the University of Sydney, and the first inhabitant of the great colony of Australia honoured with rank and title by the mother-country. May the possessors of these names long survive to reflect credit on us, do honour to themselves and good in their generation ! Nor can we omit our meed of admiration for our French *confrère*—Lescarbault, who, amidst the distractions and fatigues of a country practice, last year could yet manage to discover a new planet in the heavens, and so inscribe his own name imperishably on the scroll of astronomic fame.—Dr Radclyffe Hall.

Smoking and its Effects.—The pupils of the Polytechnic School in Paris have recently furnished some curious statistics bearing on tobacco. Dividing the young gentlemen of that college into groups, the smokers and the non-smokers, it is shown that the smokers have proved themselves in the various competitive examinations far inferior to the others. Not only in the examinations on entering the school are the smokers in a lower rank, but in the various ordeals they have to pass through in a year, the average rank of the smokers had constantly fallen, and not inconsiderably, while the men who did not smoke enjoyed a cerebral atmosphere of the clearest kind. It would be interesting to pursue this plan of statistical inquiry in our public schools and universities. Perhaps smoking is in many instances not the cause, but the effect or indication of intellectual mediocrity. Is there any connection between smoke and German metaphysics ?

The Adulteration of Food and Drink.—The new Act for preventing the adulteration of articles of food and drink has been printed, but, before it can be of public service, "Analysts" must be appointed. In the city of London the Commissioners of Sewers, and in all other parts of the metropolis, the vestries and district boards acting in execution of the Local Government Act, and the court of sessions and borough councils in other parts, may appoint one or more persons possessing competent medical, chemical, and microscopical knowledge, as analysts of all articles of food and drink purchased within such places. Any person selling articles of food and drink, knowing the same to be injurious to health, may be fined 5*l.*, with costs ; and on a second conviction, the justice may cause the offender's name to be published in a newspaper, or in such other manner, "at the expense of such offender," as to them seems desirable. There is a provision giving protection against articles being tampered with by the purchaser. A purchaser in a district "where there is an analyst appointed under this Act" may have an article of food or drink analysed for a sum not less than 2s. 6d. nor more than 10s. 6d. and to receive a certificate admissible in evidence. The justices, on complaint, may order an article to be analysed by a skilled person. An appeal is given to the quarter sessions. Persons convicted of selling adulterated patented articles may have a case stated for the opinion of the superior courts. The expenses of the Act are to be borne by the city of London, out of the Metropolis Local Management rate, and elsewhere by the county and borough rates.

APPOINTMENTS FOR THE WEEK.

Wednesday, August 29.

Operations at Middlesex Hospital, 1 p.m. ; St Mary's Hospital, 1 p.m. ; University College Hospital, 2 p.m. ; Royal Orthopædic Hospital, 2 p.m.

Thursday, August 30.

Operations at St George's Hospital, 1 p.m. ; Central London Ophthalmic Hospital, 1 p.m. ; London Hospital, 1½ p.m. ; Great Northern Hospital, King's Cross, 2 p.m.

London Home.—2 p.m.

Friday, August 31.

Operations at Westminster Ophthalmic Hospital, 1½ p.m.

Saturday, September 1.

Operations at St Thomas's Hospital, 1 p.m. ; St Bartholomew's Hospital, 1½ p.m. ; King's College Hospital, 1½ p.m. ; Charing Cross Hospital, 2 p.m.

Monday, September 3.

Operations at the Royal Free Hospital, 2 p.m.

Metropolitan Free Hospital, 2 p.m.

Tuesday, September 4.

Operations at Guy's Hospital, 1½ p.m. ; Westminster Hospital, 2 p.m.

NOTICES TO CORRESPONDENTS.

*** Dr Kidd having ceased to report for this Journal, it is requested that all communications intended for the "Hospital" Department be forwarded direct to the Editor, at the Office, 20 King William street, Strand.

H. J. B.—The indenture is still equally necessary for the Hall ; but we apprehend that the Society would relax their regulations in the case stated.

Beta.—The Marshall-Hall treatment for asphyxia in new-born children consists chiefly in rolling the body from a semi-recumbent to a semi-prone position. We are of opinion that the alternate compression of the chest and elevation of the shoulders is equally as useful a plan, and is more closely imitative of natural breathing. It is difficult to form an opinion of the real importance of the extraordinary cases reported. We must take some of these *cum grano salis*.

Dr Martin is thanked.

Dr M. (Paris).—Capt. Styles is not now in London. Dr Ross will see to the matter.

Mr W.—At the present moment there are no arrangements for sending Surgeons to the Garibaldian army. Mr W. would, no doubt, be gladly received if he could find the means of getting out. Funds will, no doubt, be soon raised.

Chirurgus.—The Grape-cure is almost as rife in some parts of France as Homœopathy in England. We know nothing of its virtues, except in the form of good Bordeaux. Dr Todd's Grape-cure is the legitimate form ; the other is quackery.

Tristis.—We cannot comply with your request.

A Three-years' Student.—1st. No.—2nd. We strongly dissuade you from such a piece of folly.

A Subscriber.—The original medical attendant certainly did not show due courtesy ; but allow-

ance must be made for some irritation of feeling under the circumstances. Your conduct was very proper.

P. P., on the Liverpool case, received.

PHILO-CIRCULAR.—An examination would be required.

Mr JAMES H.—Most certainly.

SCALPEL.—The "cutting" has been received. The subject shall have our attention.

A SURGEON'S SON.—Yes'; by canvass of subscribers.

Mr ANDERSON.—We are unable to say.

Mr J. BROWNE.—It is unnecessary.

To the Editor of the Medical Circular.

SIR,—I have read with much pleasure your able review of Dr Salter's work on 'Asthma,' and perceive that, although you sum up in its favour, you are greatly puzzled by many of his arguments.

I enclose you a pamphlet which I also published as many as twenty years ago, having first sent it in manuscript to the 'Lancet,' but without obtaining its insertion. Nor has my position in the Profession enabled me to obtain for it that publicity I think it deserves.

Some years since, I fancy, I enclosed a copy to you. If so little notice was taken of it, I do now beg of you a fair perusal and an impartial judgment. Every day convinces me that I have discovered the true pathology, and that all other theories, from Cullen to Salter, are fallacious. I have never yet met with an asthmatic man who did not endorse my opinions, and should much like Dr Salter's opinion upon my views.

I will enter into no argument here; and were I to publish a new edition of my pamphlet, I might perhaps be able to improve its style, but I do not believe I should alter a single sentence, except for that purpose. I do think I deserve to have my theory published, in common with "Bree, Bean, Todd, Budd, and Walshe," even though Dr Salter should reject it as he does theirs.—Yours, &c.,

Harpenden Hall, Herts, J. Q. RUMBALL.
August 20, 1860.

SPES.—It is probable that the examination for the degree at St Andrew's would be modfied, as regards preliminary knowledge, in favour of Licentiates, by Examination, of the Edinburgh College of Physicians who had a certain standing in the Profession; but this is merely conjecture. All examining bodies, without exception, deal more leniently with gentlemen who have been some years in practice, than with young men fresh from the schools; and it would be most unjust if they did not. The University of St Andrew's will, no doubt, act in this spirit; you can but try, at any rate.

Mr W. H.—We have no doubt of it.

AN ADMIRER.—Pax vobiscum.

A SUBSCRIBER (Co. Cork).—1st. We are unacquainted with the salaries in the Oriental Steam Company's Service. 2nd. We think that a situation as Assistant might be easily obtained.

Letters received (with enclosures) from Dr Livingston, M. F. Blundell, P. M. Keltey, and J. Denne.

Grosvenor-place School of

MEDICINE, No. 1, Grosvenor place, adjoining St George's Hospital.

The WINTER SESSION will commence on Monday, OCTOBER the 1st.

General Anatomy and Physiology, Dr Richardson.
Descriptive and Surgical Anatomy, Dr Halford.
Practical Anatomy, Dr Arlidge.
Chemistry, Dr Thudichum.
The Principles and Practice of Medicine, Dr Cockle and Dr Leared.
The Principles and Practice of Surgery, Mr Spencer Wells, and Mr Wm. Adams
Military Surgery, Mr Blenkins.

The following Prizes and Honorary Certificates will be awarded at the termination of the Session:

Gold Medal for General Proficiency.

A Prize of Ten Guineas, to be given by T. SCOTT, Esq., M.R.C.P.Ed., of the Indian Army (late a Pupil of the School), for an Essay, the subject of which is to be chosen by the Faculty, and announced in October This Prize is open for competition to all unpassed Students of the School.

The Lecturers' Prize of Ten Guineas, for competition by Students of first year only.

Certificates of Honour, for distinguished position in the individual Classes.

The Dissecting Room and Museum of Anatomy are open to the Students during daylight, where their studies are superintended by the Lecturers on Anatomy.

The Lecturer on Chemistry has a private Laboratory, where Students are instructed in Analytical and Physiological Chemistry.

Instruction in Pathological Anatomy is given by the Lecturer on Physiology.

Midwifery cases are provided for the Pupils of the Midwifery Class.

FEES.—General Fee to all the Lectures required by the Universities of London and St Andrews, the Royal College of Surgeons of England, and the Society of Apothecaries, 35 Guineas.

Further information may be obtained at the Theatre, 1 Grosvenor place; of Dr RICHARDSON, 12 Hinde street, Manchester square, W.; or at the Residences of the different Lecturers.

Sydenham College Medical

SCHOOL, SUMMER LANE, BIRMINGHAM (opposite the General Hospital). The SESSION of 1860-61 will commence on Tuesday, the 2nd of OCTOBER next.

Anatomy and Physiology—John White Keyworth, M.D., and Robert C. R. Jordan, M.D.

Practical Anatomy and Demonstration—Messrs George Elkington, Frowd Jones, and D. Johnson.

Principles and Practice of Medicine—Bell Fletcher, M.D., F.R.C.P.L., and James Russell, M.D., L.R.C.P.L., Physicians to the General Hospital.

Principles and Practice of Surgery — Alfred Baker, F.R.C.S., and David Bolton, F.R.C.S., Surgeons to the General Hospital.

Surgical Pathology—Oliver Pemberton, M.R.C.S., Surgeon to the General Hospital.

Dental Physiology and Surgery — Thomas Howkins, M.R.C.S.E.

Chemistry—Francis Wrightson, Ph.D.

SUMMER SESSION.

Midwifery and the Diseases of Women and Children—Francis Elkington, M.D., Consulting Accoucheur to the Lying-in Hospital; and V. W. Blake, F.R.C.S., Medical Officer to the Lying-in Hospital.

Materia Medica and Therapeutics—J. Bassett, M.R.C.S.E.

Practical Chemistry and Toxicology—Alfred Hill, M.D., F.C.S.

Botany—Frederick Westcott, Assoc. L.S.

Forensic Medicine—W. C. Orford, Medical Officer to the Lying-in Hospital.

Medical Tutor—C. J. Bracey, M.R.C.S.E.

Classics and Mathematics—The Rev. George Voigt, B.A.

French—F. Irlande.

This College was established for the purpose of affording a complete Medical Education. It is presided over by a Council composed of more than sixty of the most eminent Medical Practitioners of the midland counties. It is situated opposite to the General Hospital, and the hours of Lectures are so arranged as not to interfere with the attendance upon Hospital Practice. Attendance upon the Lectures will qualify for examination at all the Royal Colleges, the Army, Navy, and India Boards. Clinical Courses will be given by those Lecturers who are attached to Public Institutions in the town. The Laboratory is fitted up with every convenience, so as to enable Students to obtain a practical knowledge of Chemistry. Care will be taken to instruct Students in Practical Midwifery, and, under suitable regulations, they will be allowed to avail themselves of the Museum of the Lying-in Hospital. Prizes will be awarded in each class, and one will be given by the Council for general proficiency.

Further particulars may be obtained on application to the Principal, Dr Bell Fletcher, Waterloo street; to the Treasurer, Dr Russell, Newhall street, who is authorised to receive Students; or to the Secretaries, Mr F. Jones, 42 Newhall street; and Mr Bassett, 1 St Paul's square, Birmingham.

Middlesex Hospital Medical

COLLEGE.—WINTER SESSION.—A Course of CLINICAL LECTURES on the DISEASES of WOMEN and CHILDREN will be delivered by Dr PRIESTLEY to the Students in this College.

The Middlesex Hospital

MEDICAL COLLEGE. — The INTRODUCTORY LECTURE will be delivered by Dr CHARLES COOTE, late Fellow of Pembroke College, Oxford, at Eight o'clock on Monday Evening, OCTOBER 1.

The Middlesex Hospital contains 305 Beds, and has Special Wards for Cancer, for Venereal and Uterine Diseases.

STAFF:—Dr A. P. Stewart, Dr Goodfellow, Dr H. Thompson, Physicians; Dr R. T. Prere, Physician-Accoucheur; Dr F. Weber, Dr C. Coote, Assistant-Physicians; Mr Shaw, Mr De Morgan, Mr Moore, Mr Henry, Surgeons; Mr Nunn, Mr Flower, Assistant-Surgeons; Mr Temes, Dental Surgeon.

LECTURES IN THE MEDICAL COLLEGE:—Dr A. P Stewart and Dr Goodfellow, on Medicine; Mr Shaw, on Surgery; Mr De Morgan, on Physiology; Mr Moore, on Anatomy; Mr Nunn and Mr Flower, on Practical Anatomy; Mr Taylor and Mr Heisch, on Chemistry; Mr Sibley and Dr Murchison, on Pathological Anatomy; Dr Priestley, on Midwifery; Dr H. Thompson, on Materia Medica; Dr Woodham Webb, on Minute Anatomy; Mr Henry and Dr C. Coote, on Forensic Medicine: Dr Lawrence, on Botany; Mr Taylor and Mr Heisch, on Practical Chemistry; Dr T. Spencer Cobbold, on Comparative Anatomy. Instruction in Modern Languages by Dr Buchheim, Ph.D. Vienna.

The opportunities for gaining practical knowledge have been recently increased. There are now FIVE APPOINTMENTS, with residence within the Hospital, and free commons, for which Students who have completed their education in the College are, under certain conditions, eligible.

In addition to Prizes for General Proficiency, the Governors' Prize of Twenty Guineas is given for excellence in Clinical Reports.

For the Hospital Practice and Lectures required by the College of Surgeons and Society of Apothecaries, the fee is £83 4s., payable by yearly instalments, of which the two first are £35 each. A full prospectus forwarded on application.

T. W. NUNN, Dean.
C. DE MORGAN, Treasurer.

WATER BEDS AND CUSHIONS.

A Preventive against Bed

Sores, &c. Bed Sheets, Air Cushions, and all necessary Utensils for Invalids.

BENHAM and Co.,
Practical India-rubber Workers, 118 Oxford Street, W.

Manchester Royal School

OF MEDICINE AND SURGERY, Grosvenor street, Piccadilly.

SESSION 1860-61.

The WINTER TERM will commence on Monday, OCTOBER 1st, when the INTRODUCTORY ADDRESS will be delivered by Mr LUND, at Twelve o'clock.

WINTER LECTURES.

Physiology, by Mr Turner and Mr Smith.
Descriptive Anatomy and Dissections, by Mr Lund and Mr F. A. Heath.
Chemistry, by Mr Stone.
Principles and Practice of Medicine, by Dr Browne.
Principles and Practice of Surgery, by Mr Dunnville and Mr Southam.
Anatomy, Physiology, and Pathology of the Eye, by Mr Hunt and Mr Lund.

SUMMER LECTURES.

Obstetric Medicine, by Mr Heath.
Pathology, by Mr Roberts.
Materia Medica, by Mr Somers.
Forensic Medicine, by Mr Greaves and Mr Morley Harrison.
Botany, by Mr Grindon.
Practical Chemistry, by Mr Stone.

Hospital Practice at the Royal Infirmary, where Clinical Lectures on Medicine and Surgery are regularly delivered by the Physicians and Surgeons of the Institution.

SCHOLARSHIPS.—In addition to Prizes for General Proficiency and Certificates of Honour, Three Scholarships for perpetual Students will be offered for competition; one of £20, for third-year's Students; one of £15, for second-year's students; one of £10, for second-year's Students.

Further particulars may be obtained from Mr SOUTHAM, 21 Lever street.

August, 1860.

For Family

ARMS—Send Name and County to the ROYAL HERALDIC STUDIO and LIBRARY; in a few days you will receive a Correct Copy of your Armorial Bearings. Plain Sketch, 3s.; in Heraldic Colours, with Written Description, 6s.; Large Size, 12s. Family Pedigrees, with original grant of Arms, to whom and when granted, the origin of the name, all traced from authentic records, fee Two Guineas. An Index containing the Names of nearly all Persons entitled to use Arms, as extracted from the British Museum, Tower of London, Heralds' College, &c. &c. The Manual of Heraldry, 400 Engravings, 3s. 6d., post free.—By T. CULLETON, Genealogist, Lecturer on Heraldry at the Mechanics' Institute, 25 Cranbourn street, corner of St Martin's lane, London, W.C. The Heraldic Colours for Servants' Liveries, 5s.

Arms, Crests, &c., Engraved

in the Best Style. Crest on Seals or Rings, 7s. On Steel Die, 6s. Initials, 1s. 6d. per Letter. Book Plate, Engraved with Arms, 10s.; or Crest, 5s. Postage and Registered Letter, 1s. extra. T. CULLETON, Heraldic Engraver, by Appointment to the Queen, 25 Cranbourn street, corner of St Martin's lane, London, W.C.

Solid Gold Ring (18 Caret,

Hall Marked), Engraved with Crest, 42s.; Large Size, for Arms, 75s. On receipt of P.-O. order the sizes will be sent to select from. T. CULLETON, Seal Engraver, 25 Cranbourn street, corner of St Martin's lane, London, W.C.

Stamp your own Paper—

with Arms, Crests, Initials, or Name and Address, by means of CULLETON'S PATENT EMBOSSING PRESS, 15s.; Best Make, 21s. Any person can use them. T. CULLETON, Die Sinker to the Board of Trade, 25 Cranbourn street, corner of St Martin's lane, London, W.C.

Family Arms, &c.

Emblazoned for Painting on Carriages or Needlework, 6s.; Best Style, 12s., Gothic and Modern Monograms Designed, 5s. Arms Quartered, Impaled, and Painted on Vellum, according to the Laws of Heraldry. By T. CULLETON, Seal Engraver and Die Sinker, 25 Cranbourn street, corner of St Martin's lane, London, W.C.

Wedding Cards—For Lady

and GENTLEMAN — 50 each. 50 Embossed Envelopes, with Maiden Name, Printed Inside, 13s. Visiting Cards—A Copper Plate Engraved in any Style, with Name and 50 Cards, Printed for 2s., post free.—N.B. All Orders executed by return of post, for Stamps or Cash.—T. CULLETON, Seal Engraver and Die Sinker, 25 Cranbourn street, corner of St Martin's lane, London, W.C.

The Pen Superseded.—Mark

your Linen. The best and only method of Marking Linen, Silk, Stockings, Coarse Towels, or Books, so as to prevent the Ink washing out, is with CULLETON'S PATENT ELECTRO-SILVER PLATES. By means of this novel invention a thousand pieces of Linen can be Marked in a few hours. Initials, 1s. each; Name, 2s. 6d.; Set of Moveable Numbers, 2s. 6d.; Crest Plate, 5s., with the necessary Directions for Use. Post free.—Certificate from the eminent Dr Sheridan Muspratt, F.R.S., Professor of Chemistry, &c.

All Orders to be sent to the Patentee and Sole Maker, T. CULLETON, 25 Cranbourn street, corner of St Martin's lane, London, W.C.

Chlorodyne. — R. Freeman,

Pharmaceutist, Kennington road, London, S., informs the Profession and Trade that he has FOR YEARS MADE, and extensively used in his business, Chlorodyne; and that he is supplying it in one-ounce stoppered bottles at 1s.6d. each, and in four-ounce bottles, 5s. each. He guarantees it to be uniformly and properly prepared, and superior to any other makers', though their charge be ever so exorbitant; and he trusts that the lowness of price at which he offers it will allow the Profession to use it in common practice and at public institutions, so that its extraordinary beneficial effects may be enjoyed by the poorest sufferer. Sold by all Wholesale Druggists.

Allen's Portmanteaus

and TRAVELLING BAGS with square openings. LADIES' DRESS TRUNKS, DRESSING BAGS with silver fittings.

DESPATCH BOXES, WRITING and DRESSING CASES, and 500 other articles for home or continental travelling, illustrated in the New Catalogue for 1860. By post for two stamps.

J. W. ALLEN, late J. W. and T. Allen, Manufacturers of Officers' Barrack Furniture, and Military Outfitters See separate Catalogue), 18 and 22 Strand, London.

Diphtheria, Clerical Sore-

Throat, Loss of Voice, and other diseases of the mucous passages of the throat, successfully treated with Solution of Caustic by Tompson's Patent Hydro-Pneumatic Inhaler (easy of self-use), without pain or inconvenience. To be seen at the Museum of Patents, South Kensington, and the Agents', Milliken and Lawley, Surgical Instrument Makers, 161, Strand, adjoining King's College, London.

Mr Maurice, Dentist,

316 Regent street (opposite the Polytechnic), by adopting every IMPROVEMENT in ARTIFICIAL TEETH and GUMS, is enabled to meet the requirements of the most difficult cases at very economical prices, no charge being made unless satisfaction be given.

Flour — (Essex) — War-

ranted free from adulteration, to any part of London (not less than 14lbs.) carriage free. Whites, for pastry, per bushel (56lbs), 10s. 4d.; Households (recommended for bread-making), 9s. 8d.; Seconds, 9s.; Wheat Meal for brown bread, 9s. Best fine and coarse Scotch Oatmeal. Address HORSNAILL and CATCHPOOL, Bullford Mill, Witham, Essex, or 97 Goswell road, City road, E.C. Directions for bread-making gratis. Terms Cash. A half sack delivered free to any rail station 200 miles. German Yeast.

Child's Patent Galvanic

ELECTRO HAIR and FLESH BRUSHES. No trouble in use. Effect certain in all cases of Galvanic Action, these Brushes containing battery of sufficient force to be perceptible in use. The Profession will find them of great advantage in all cases of Neuralgia and Rheumatic affections, being a pleasant and refreshing means of applying galvanic action to the surface of the skin.

To be had at the Manufactory, 21 Providence row, Finsbury square.

Galvanic Institute,

52 Euston road.

These rooms have been opened under the superintendence of registered qualified Medical Men, for the legitimate application of Galvanism in the treatment of Nervous Diseases, Paralysis, Rheumatism, Asthma, Indigestion It will also assist in affording the means of taking this branch of practice out of the hands of the unqualified. Hours of attendance twelve to five (Sundays excepted).

Ordinary Medical Attendant, Mr J. Smellie, Surgeon.

TO THE PROFESSION.

Messrs M'Gowan & Danks

(THE PRINTERS OF THIS JOURNAL)

Are prepared to forward Estimates, to those requiring the same, for any description of Work connected with the Printing Business.

Messrs M'G. and D. are enabled, from the facilities which they possess, to execute whatever may be entrusted to them with economy and despatch.

Letters addressed to No. 16 GREAT WINDMILL STREET, HAYMARKET, will meet with immediate attention.

*** There is at the present time an opening for the Printing (and Publishing if wished) of a Weekly Periodical.

Mr Mapleson, Dentist,

(Cupper to the Queen), has REMOVED to 71 Wimpole street, Cavendish square.

Mr Mapleson's Pamphlet on the Mechanical Treatment of Cleft Palate may be had on application at his residence.

ÆGLE MARMELOS, OR INDIAN BAEL.

Liquor Belæ, prepared from

the unripe fruit, so much esteemed in cases of Diarrhœa, Dysentery, &c.; also the Wine, Extract, Powder, and Preserve.

Descriptive accounts may be had on application to the Importer.

J. C. GOULD (late POUND), Pharmaceutical Chemist, 198 Oxford street, London: West-end Agent for PALMER'S CHALYBEATE WATER, and the celebrated OSWEGO CORN FLOUR for Invalids, &c.

PULVIS JACOBI *VER.*, NEWBERY'S.

GENTLEMEN,—We beg to call your attention to the following paragraph by "*J. Cheyne, M.D.*, Physician to the Hardwicke Fever Hospital, Dublin, *in his paper on the virtues of James' Powder in the Apoplectic Diathesis*:"

"She began a course of James' Powder in the latter end of September: the first night she took only two grains, and every succeeding night an additional half grain, till the dose amounted to twenty grains. She took *twenty grains every night for five weeks*, when she found herself so well that she discontinued the medicine."—"*Dublin Hospital Reports*," *vol.* I. *p.* 319.

To secure the dispensing of the *original* preparation, which, for 114 years, has been sold by the Newbery family in St. Paul's Churchyard, it is necessary to prescribe it as "*Pulvis Jacobi* Ver., *Newbery's*," otherwise another article (wanting in the best properties, and recommended to be given in a different code of dose, *though called by the same name*), will be substituted for the original medicine. This, of course, cannot but have an effect other than that expected, and will thereby lead the practitioner totally to discard it from his daily Pharmacopœia, as a preparation whereon no dependance can be placed. We hope the above extract will prove that when the genuine medicine is used, faith may be reposed in it.

Yours faithfully,

F. NEWBERY & SONS.

45, St. Paul's Churchyard.

Wood and Watson's South

African Port, Sherry, &c., 20s. per dozen. Pint Samples or 12 stamps each. Excellent Brandy, 16s. per gallon.

Pale India Ale and Stout, 4s. 6d. per dozen quarts, 2s. 9d. per dozen pints. Scotch Ale, 5s. 6d. per dozen quarts, 2s. 9d. per dozen pints.

Address, 16 Clement's lane, City, E.C.

Newton Wilson and Co.'s

World-famed PATENT.—THE NEW PATENT NURSING CHAIR, in which the child nurses, amuses, exercises, and weighs itself, is a marvel of ingenuity and utility, unanimously recommended by the Press and the Faculty. No family should be without one. Price 12s. 6d. upwards. Prospectus free.

WILSON'S PATENT CARPET SWEEPER, which cleans a carpet thoroughly without labour, without injury, and without raising a grain of dust. Price 15s.

Newton Wilson and Co., 144 High Holborn, London.

For Correct Family Arms,

CREST, or PEDIGREE, send name and country, and 7s. 6d., to J. LOCK'S City Heraldic Office, No. 2 Old Jewry, E.C., London, and in a few days you will receive a neat drawing of your Arms, &c., in Heraldic Colours, to be engraved on Seal, Ring, or Family Plate. On y parle Français, Italien, Allemand, et Hollandais. Wedding orders executed.

Aërated Lithia Water.—

Messrs BLAKE, SANDFORD, and BLAKE are prepared to supply the LITHIA WATERS (of which they were the original manufacturers under Dr Garrod's instruction) of any strength prescribed by the Profession for special cases. Those in constant use contain two grains and five grains in each bottle, either by itself or combined with BICARBONATE of POTASH or PHOSPHATE of AMMONIA.—Also, Potash, Citrate of Potash, Soda, Seltzer, Vichy, and Mineral Acid Waters, as usual.

BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists, 47 Piccadilly.

Neuralgia, Nervous Headaches, Rheumatism, and Stiff Joints Cured, and

Grey Hair Restored to its Natural Colour, by

F. M. HERRING'S PATENT

Magnetic Brushes,

10s. and 15s.; Combs, 2s. 6d. to 20s.

N.B. — The Electro-Galvanic Brushes were formerly made and sold by F. M. H., but the dirt and trouble inseparable from a galvanic apparatus were insurmountable obstacles to their use.

Offices, 32 Basinghall street.

The Cheapest House in the

Kingdom for DEMYS and GENERAL STATIONERY.

A. W. DIGBY and CO.'s, 90 Chancery lane, London, W.C.—White Demys, 7s. 6d., 8s., 8s. 6d., 9s. 6d., 10s. 6d., 11s. 6d., 12s., 12s. 6d., 13s. 6d., and 15s per ream: Blue ditto, 6s. 6d., 7s. 6d., 10s., 12s. 6d., 15s.: Fast Blue, 11s. 6d. and 13s. 6d. Capping and Filtering equally cheap. Note Paper, 2s. 4d., 3s., 3s. 9d., 4s. 6d., 5s., 6s. 3d., 7s., 8s. 6d. Crests made and stamped. Envelopes from 3s. per 1000: Day Books, Ledgers, and Prescription Books to order. Cards, Circulars for Professional Attendance, and every description of Printing.

A. W. D. and Co. have purchased the major part of the stock of Demys of the late Firm of Hoe and Ham advertised as "Patent Demys."

CLINICAL LECTURES.

ON THE TREATMENT OF FRACTURES IN CHILDREN.

DELIVERED AT THE HÔPITAL DES ENFANTS,

By M. GUERSANT.

In the treatment of fractures in children, we are met by the same questions that occur to us in the treatment of fractures in adults; and we have still to consider whether mechanical appliances are always necessary in the fractures of the former, or whether in some cases position alone would not suffice, as had recourse to by some surgeons in the case of adults. We shall at once reply, that such means seem to us useful in almost every instance; and for many reasons. In fact, as children pay little or no regard to what they are told, but move themselves constantly in spite of the pain they occasion themselves, they thus, beside other mischief they do, tear asunder the adhesions that would still have maintained in contact the fractured surfaces. Moreover, as it is not unusual in these young subjects to see convulsions occur as a consequence of fracture, and, though more rarely, tetanus itself, when fractures are complicated with wounds, it will be always well to produce immobility of the fractured portions, with a view to prevent such possible complications. Such appliances, then, would in every instance be advantageous, were you thereby only to prevent the occurrence of such symptoms, and quiet the solicitude of your patient's friends. The question of their necessity being thus answered, ought mechanical means, as recommended by Dupuytren, to be at once applied; or should we temporise, as recommended by the example of Lisfranc? Except in particular cases,—those, for example, where there is great mutilation,—we deem it at least prudent in young subjects to have the fractured limb as soon as possible rendered immobile.

We shall now consider how we should proceed in reducing, and keeping reduced, fractures in children. I need not here insist on the manner of practising extension, counter-extension, and coaptation. When, as in adults, you have ascertained that displacement exists, the fragments are next to be drawn by assistants in opposite directions, and their hold should be at points as distant as possible from the seat of the lesion. The Surgeon in the mean time endeavours to reduce the fractured surfaces to their proper relation by using pressure over the fractured extremities. Fractures in persons of this early age present one peculiarity, which is, that but little force is required to overcome and rectify their displacement. Even in patients of thirteen or fourteen years, moderate extension will suffice to accomplish the reduction; and, for the rest, we have already seen that when young children are the subjects, there is but little tendency in the fragments to become displaced. The fracture being reduced, or requiring no reduction, should we make use of appliances that may be removed at pleasure, or such as do not admit of such removal? In order to decide, I would in every case refer you to the indications. You have seen us prefer, before every other, an apparatus that can be easily removed whenever it has been desirable to inspect the seat of fracture. Now this is the case whenever the soft parts have been divided, or when there is reason to fear that displacement may be again occasioned. On account of the smallness of the limb, immobility is more easily attained than in grown persons; and thus you can without inconvenience remove and replace an apparatus, so as to lay bare and inspect the seat of the evil.

There is still another reason that frequently makes us prefer a removable apparatus where children are the patients. When the fracture occurs in one of the lower extremities, and the patient's habits are not cleanly, it often happens that the bandages get soiled with urine. If in such cases you apply an apparatus covered with dextrine, or even plaster, it gradually becomes softened, and ceases to fulfil the end for which it was designed. On the contrary, in every case where there is no wound, and you neither have reason to fear displacement, nor contact with a liquid that would soften or prevent the induration of the apparatus, the preference is to be given to non-removable appliances. We have recourse also to such when these inconveniences are no longer to be feared. Hence it is that in the same patient you sometimes see the treatment begun with the former kind of apparatus, and finished with the latter. On the whole, it may be said that generally the indications that point out the use of a removable apparatus are more frequently seen than those that would lead us directly to employ one of a contrary kind. As you have so often seen at the bedside our mode of procedure, I shall not now insist on the manner in which the appliances are to be kept immovably in their place, since long verbal descriptions are not comparable to such practical demonstrations. I cannot, however, refrain from recapitulating what you have seen in our wards, and pointing out to you, in a very succinct way, the manner of applying the various sorts of apparatus in various fractures, beginning with those of the superior extremities.

Fractures of the cranium, those of the ribs and of the scapulæ, do not in children offer, as in adults, any special point for practical consideration. In such cases I am satisfied with applying a simple body-bandage round the chest. But in fractures of the clavicle it is different, and these are far from being rare in children. No month possess that we have not occasion to see several cases of this kind, either in our wards or consultations. These fractures in young subjects are usually incomplete, for the periosteum, and even sometimes the osseous fibres, resist the traumatic action. Having usually no displacement to contend with, it suffices, in order to obtain regular consolidation and avoid secondary displacement, to maintain the arm resting against the trunk, and the forearm across the breast, by several turns of a bandage passing obliquely from the shoulder of the sound side under the elbow of the injured side. Care must be taken to raise the shoulder firmly, and then to fix the turns of the first bandage by a circular bandage embracing the thorax. You can very well attain the same end with Mayor's bandage, which is sometimes employed in place of roller bandages. When the fractured ends do not override, there is no occasion for the wedge-like cushion recommended by Desault. This cushion, which is designed to be a fulcrum to the humerus, so that it may act as a lever on the scapula and bring outwards the outer fragment of the clavicle, would in such cases be useless.

In fractures of the middle part of the arm, we employ the common roller bandage with three splints, but no graduated compresses. Nor do we apply any splint on the internal part of the arm, by which we avoid pressure on the vessels and nerves. The round limbs of children have neither ridges nor depressions; consequently, graduated compresses are not only not required, but would rather be hurtful by producing unequal pressure on the injured parts. We begin by enveloping the membrane in a circular bandage, taking care to defend the flexure with carded cotton. When the fracture is at one or other extremity of the humerus, we rest satisfied with applying a roller bandage, so as to maintain the member motionless. Splints here would serve no purpose, since they would not bear on both fragments. For fractures in the middle of the forearm, it is sufficient, as in the case of adults, to produce compression, in the direction of the interosseous space, by two splints maintained in position by a bandage, or by strips of adhesive plaster. Here graduated compresses are useful. In fractures of the lower extremity of the radius, we make use of the same apparatus, observing the precaution of placing the hand obliquely on the side of the ulna. Fractures at the elbow are often seen at this early age, and deserve the greatest attention from the surgeon.

An attentive examination will prevent your mistaking fracture from dislocation of the elbow. The fracture being ascertained, what should be your procedure? If the joint is painful and much swollen, the first thing to be done is the application of leeches; and nothing should be omitted that may prevent, or moderate as much as possible, the effects of traumatic inflammation of the joint—always serious in children. The inflammatory symptoms once subdued, your attention may next be given to the fracture, if it yet be time. Now, the indications are different according to the seat of the fracture. When it is the olecranum that is separated from the ulna, the forearm is to be maintained in a state of perfect extension by a cushion and splint placed on the arm. The triceps is thus relaxed, and the fragments better approximated than by any other position. But should you ascertain that the coronoid apophysis has been broken off, it will, on the contrary, be necessary to keep the forearm bent by a figure-of-eight bandage passed from the arm to the forearm, with sufficient wadding interposed to protect the cutaneous surfaces that would otherwise be placed in contact. When the injury done to the articular surfaces is so great as to compromise at a later period the motions of the joint, the precaution should be taken of keeping the forearm bent at a right angle with the arm, so as to avoid, in case of anchylosis, a more unseemly position. Fractures of the hand and fingers occur under the same circumstances as in the adult, and are to be treated in the same way; that is, the hand is, every part, to be secured against a suitable splint.

(To be continued.)

ON THE TREATMENT OF GONORRHŒA WITHOUT SPECIFICS.

By J. L. MILTON, Esq., M.R.C.S.

(Continued from page 138.)

First Class. — Gonorrhœa of long duration simply owing to neglect.—The discharge is generally not great in quantity, and is not accompanied by much chordee or scalding on or after making water. Such cases generally yield to a mild aperient, as the infusion of rhubarb with soda, and an injection two or three times a day.

But if, at the end of thirty days, no improvement has been effected by these or any other means, the bougie may at once be passed; for every variety of discharge may be accompanied by more or less stricture, and the only sure proof of no contraction being present is that a bougie will pass.

Should this exist, it is needless to say that it requires its special treatment; a subject into which I cannot go here.

But if no stricture be detected, I would advise that the penis should be blistered without delay, and whatever form of counter-irritant the surgeon may choose observation will soon show him that there should be complete vesication; so soon as the soreness has passed off, mild injections can be employed. In most of these cases a single

blister effects a cure; in few does a second fail; if it should, the use of the bougie, and touching the posterior part of the urethra gently with the nitrate of silver, will, assisted by a mild aperient and tonic, generally effect a cure.

As what I said on the subject of blistering has drawn forth some very erroneous remarks, I take the opportunity of placing the subject in its true light. I never thought of claiming the credit of having *discovered* that blisters cure gleet. I knew that blisters to the perinæum had been recommended long before I was born; nay, even in Hunter's time they were used for this purpose; but I believe, that if other surgeons had ever resorted to blistering *the penis*, the remedy had at the time I broached the subject fallen into very undeserved desuetude; so much so, that I found no trace of the practice in all the works I have read. Of course, it is easy in all such cases to rake up some claim to priority.

A blister is one of the most powerful remedies that can be employed. It will cure almost any case that is not complicated with stricture. So far as my experience goes, it is, when properly employed, the most efficacious remedy we possess in many cases.

I have heard it condemned as a violent remedy. I deny it, and appeal to the fact that many patients cured by it of gonorrhœa and gleet have, on being a second time infected, blistered themselves of their own accord.

And why should surgeons hesitate to blister in gleet? They are not so scrupulous about using such a remedy in the vicinity of the eye, the most delicate organ in the frame. Why should the penis be the only part of the frame which we cannot vesicate? If patients complain of such trifling discomfort, it only shows how inconsistent and ungrateful man is. They must, then, really expect to be cured of these disorders without any sacrifice of trouble or convenience. If they had lived a century ago, they would have been only too glad to avail themselves of what we are now said to look upon as a "nuisance." (*a*) In order that a blister may be properly applied, there are some points which, however trivial they may seem, require as much attention as the leading features of the case. Where these are neglected, blistering is apt to produce such a filthy, excoriated mess, that the patient will not submit to it a second time; whereas, if carefully laid on and dressed, it is, from its being out of the reach of friction in the ordinary movements of the body, even less troublesome than if on a limb or the trunk.

Before putting it on, a little of the hair at the root of the penis is cut off; and if the foreskin be naturally retracted, it must be drawn forwards over the glands. A piece of paper is then to be fitted on the penis, and cut till it exactly covers it from the root to within half an inch of the mouth of the urethra. This is then laid down on the blister, which is cut out by it, wrapped round the penis, and fastened with threads behind the glans and near the root.

The patient should remain perfectly quiet during the time it is on, lest any motion should bring the blister against the scrotum, and vesicate it: but he must not apply it on going to bed, or he will most likely fall asleep, and not awaken till the penis is one mass of vesications, a state productive of an unnecessary amount of suffering.

In the milder cases, or where the skin is tender, an hour or an hour and a half will be sufficient. The blister is then removed: if there are any vesicated spots, they are covered with pieces of linen spread with zinc ointment, and then a layer of cotton is bound over these, and covered with a piece of linen, kept on by a thread, or, what is better, two very thin rings of vulcanised Indian rubber.

Where a severer case renders a more energetic employment of the remedy necessary, it must be kept on three or four hours until free vesication is produced; zinc ointment is then applied. To protect the penis from friction, a T bandage, with a linen bag sown into the part which receives the penis, or a handkerchief carried round the waist and dipping in front so as to receive the penis and keep it up against the abdomen, is necessary.

The first effect of this application is to increase the discharge considerably, which then terminates either by altering its character, becoming ropy and mucous, and finally disappearing in a few days, or by remaining somewhat more persistent, and requiring a few injections, when the penis is so far advanced towards healing that it can be handled without pain. It may, however, demand even a second blister. One of the most cleanly and convenient, and least painful forms of blister, is Brown's cantharadine tissue; it causes much less irritation, and heals much more quickly than the emplastrum lyttæ.

The blistering fluids, if strong enough to vesicate, caused such pain that I soon renounced the employment of them, though they are very useful applied to the perinæum.

For three or four days after the application of the blister in question, the patient is better. So soon, however, as the blistered surface begins to heal up, a few mild injections may be given. The bowels should be kept gently open.

Now and then it will happen that the patient is mortified and surprised to find the discharge reappearing at the very moment he thought all gone. Thus, on the third day there may be no discharge, and on the fourth there is a good deal; but this generally subsides as rapidly as it appeared, if the patient will only abstain from tampering with it.

How does this remedy act? By counter-irritation, will perhaps be the answer. But, if this were the case, why should there be increased action in the urethra for a few days, and why should the discharge from the urethra begin to disappear when the counter-irritant surface is healing up? It would seem as if the organised constituents of the urethra are capable of keeping up a certain amount of over-action for an indefinite time; but that, when hurried beyond this by a healthy stimulant, *a rebound* takes place, which leaves them less capable than before of furnishing a secretion, morbid in amount or in quality, or in both.

Second Class.—Intractable Gonorrhœa.—If the case, however, be more severe, accompanied by a good deal of scalding and pain, often most marked opposite the junction of the under side of the penis and scrotum, it will, if recent, often be found connected with stricture; but if of some standing, as eighteen months to two years, there is usually none. For if stricture does come on in these bad subjects, it soon becomes so marked as to make the diagnosis quite certain; if at the end of six months the canal remains quite free, my experience is that it will be equally free at the end of a year.

In every case of this kind, whatever may have been the previous duration of the disease, I can see no objection to its being treated at once as acute gonorrhœa, and perhaps a small number of these cases may be cured; certainly many of them are somewhat relieved. Here, also, if at the end of thirty days no improvement is effected, the disease will in most cases not yield to ordinary treatment. Hence, at the end of this time I at once blister the penis and order a smart purgative, treating the case subsequently as in the preceding class.

Many surgeons have thought that a tendency in discharge from the urethra to relapse, whenever the patient indulged in wine or connection, should make the surgeon suspect stricture. Sir E. Home seems to have leaned to this opinion. Others, Jesse Foot among the number, considered that gonorrhœa could hardly endure very long without inducing structural change in the urethra. Neither rule holds always good. I have treated numerous cases of bad stricture in which nothing of the kind occurred; and I have cured old cases of gonorrhœa, and long afterwards found the urethra quite free. Thus, in a patient cured in 1849 of a gonorrhœa of six years' duration, there were, three years ago, no symptoms of stricture; yet more than one surgeon, when informed by this gentleman that his gonorrhœa had on four occasions become virulent after connection, had declared that the case could only be treated by the bougie.

Third Class.— Muco-purulent Gleet. — When there is but a small quantity of muco-purulent discharge, with little or no swelling, accompanied by pricking pains in the urethra—when the history of the case is, that the patient has given his surgeon fair play, and the orifice of the urethra looks narrow—the bougie may at once be passed, however confidently the patient may assert that the opening never was any larger, and that he makes water as well as ever he did. In all these cases I have found stricture, with one exception, in which the patient had a small fistulous opening behind the frænum, and so habitually placed his finger there to stop the urine that he never thought of telling me.

To this class of cases may be added those when the discharge is thin, or seems broken up, as if some portions of it were more consistent than others, or slightly coloured with brown. Here I have sometimes succeeded in arresting the discharge, and the patient has come back months after with stricture. Hence I now always resort at once to the bougie.

If there be much muco-purulent discharge, a mild injection may also be used; but where there is only sufficient to glue the lips of the urethra together, the necessary relief will be derived from injections of pure water.

In many of these patients the health is a little out of order, principally, I think, from their having taken so much medicine. Small doses of quinine, a mild aperient pill once or twice a week, and, when there is pain in making water, an ointment containing twenty grains of Morson's veratrine to ℥j of lard rubbed below the urethra, will generally effect a good cure.

A free discharge of mucus from the urethra unaccompanied by pus is not very common, at least I have only seen few cases of it. But for the anxiety it causes the patient, I should say the best treatment was to let it alone. I have tried various astringent injections, among others that of green tea, without much result.

Occasionally the resins, such as Chian turpentine, in doses of ten grains, or the inspissated essence of spruce, fir, or pine, in the same dose, twice a day, are of some avail, particularly if the bladder be involved.

It may be asked, how is it that gonorrhœa affects some persons so differently? Is it owing to the prevalence of a rheumatic, gouty, or scrofulous diathesis? Such an explanation has been suggested, or rather invented. (*a*)

In October, 1854, I read before the Medical Society of London an analysis of thirty-three cases of the most obstinate gleet treated in this way. The reader will find the paper reported in the journals of that date; and he will likewise find that one speaker objected, that the paper had been compiled in a hurry—which was true, as it had only taken the Author about five years to collect the materials, and which will hardly apply now.

Rejecting all the complicated cases, there were twenty-three of those which were uncomplicated; and in them a complete cure was effected, twenty by blistering alone, though the disorder had in some of them lasted six or seven years.

Subsequent experience has amply justified the conclusion long ago arrived at: I have now cured above a hundred cases of this tiresome complaint by the means I have sought to enforce.

There were also two cases in which blistering failed. In one the discharge had lasted twelve years, and when first cured by blistering, was brought on again by an abscess of the perinæum. In the second and third there was also this com-

(*a*) Langston Parker, 'Modern Treatment of Syphilis,' third edition.

(*a*) "Gleet may arise from rheumatism, scrofula, venereal poison"—(Wallace)—for it seems to be purely gratuitous; a sort of mystification which melts away when we put it to the test. As a rule, I never could trace anything of the kind. In one patient who had suffered from abscess in the perinæum, there were rheumatic pains; and another, who was also the subject of abscess, had in early life been afflicted with scrofulous ophthalmia of the eyelids. All the rest appeared quite as healthy as the average of men, and presented every variety of temperament.

We see men of a particularly delicate, unhealthy appearance throw off gonorrhœa with the greatest ease, while in others, blessed to all appearances with the best of health, the first attack brings on stricture and abscess. We find that in men of a like temperament, the disorder often runs a course so different, that no experience will enable us to predict its duration or the results it will entail. The coarse formulæ of temperaments form no guide for prognosis in diseases of the generative organs, where alone inflammation can go on for years without injury to the health or marked change of structure; and I have equally failed in tracing the peculiarity to faulty development of the generative organs, to any influence of the weather, or to irregular habits: in short, the only inference I can draw is, that it results from an inborn infirmity in the secreting apparatus of the urethra, and that imperfect evolution of cell and fibre has more to do with it than bodily features.

plication: the one left almost cured, the other neglected it and got stricture. Three more had stricture, which was only revealed by the failure of the blister inducing the patients to allow the bougie to be passed. One was pure mucous gleet, over which all remedies seem powerless. Of the three uncomplicated cases in which it failed, one was cured by caustic; the remaining two patients left dissatisfied.

The reasons for this disparity of results and the rules for attaining greater success have already been given. If the means spoken of do not avail in a few solitary cases to remove the discharge entirely, they will yet cure every symptom of the slightest moment.

VALE!

THE PHYSIOLOGY OF THE SYMPATHETIC SYSTEM OF NERVES.

By JAMES RORIE, M.D., &c.

Having in a former number of this Journal considered the action of the sympathetic system on the Heart, we will now proceed to discuss its influence on the Blood-vessels.

It is to the experiments of Bernard and Brown-Séquard that we are chiefly indebted for our knowledge as to the influence of sympathetic nerves on the movements of the blood-vessels. Claude Bernard first discovered that section of these nerves was followed by increased redness of the head and neck; and subsequently, both he and Brown-Séquard found that galvanism applied to the cut end of the nerve produced an opposite effect. Other writers, however, have also pointed out the importance of the sympathetic nerves on the vascular circulation. Thus, "The experiments of Walther on the frog," says Drummond, in his paper in the 'Cyclopædia of Anatomy and Physiology,' "would also indicate that the circulation is more or less influenced by the sympathetic nerves." When the fibres which are sent by the sympathetic to the nerves of the lumbar plexus were divided, he found, on examining the circulation in the web of the foot, that "although at first undisturbed, it very soon afterwards increased in rapidity. The capillaries appeared to be dilated, and contained fewer corpuscles than corresponded to their calibre: the increase in their diameter equalled from one-sixth to one-eighth of the calibre of the vessel. After a time the rapidity of the circulation again diminished, and in some parts it became stagnant." Again, "in the frog also, when the lumbar plexus was divided, the animal continued for two or three months without any disturbance being observed in the nutrition of the limb; but when several of the lumbar ganglia were removed, dropsical effusion into the abdominal cavity, and inflammation of the peritoneum ending in the death of the animal, ensued in the course of two weeks."

This condition of the vessels, however, cannot long continue without serious and important changes taking place in the functions of the organs to which they are distributed. We thus have induced

Changes in Nutrition.—The experiments made with reference to this subject are by no means numerous, but what have been observed are very illustrative of the influence of the sympathetic system on nutrition. Thus, it has been observed by Valentine "that removal of the upper cervical ganglion was followed by injected conjunctiva, increased secretions of the eye, and inflammation of the cornea; conditions which continued for many months after the operation;" and by Krimer, "that division of the renal nerves gives rise to changes in the constitution of the urine, this secretion in such cases containing albumen and colouring matter of the blood, with a corresponding decrease of its normal elements.

The above results are sufficient to show the influence possessed by the sympathetic nerves over the functions of secretion and nutrition, and the serious effects which must result from their injury; but this part of our subject will be treated of at length when we come to consider their pathology.

III.—*Influence of the Sympathetic Nerves over the Movements of the Genito-Urinary System.*—Is the contraction of the uterus due to cerebro-spinal action? is a question which has often been asked by physiologists, but very vaguely answered. That the pains of labour can be stopped by a voluntary effort, is the reason held by some authors for answering in the affirmative; while the facts shown by Professor Simpson, that labour can be completed while the spinal cord has been in a great measure destroyed, and that paralytic women experience no difficulty in parturition, are equally valid reasons for replying in the negative.

The solution of this question, I have little doubt, lies in the principle formerly enunciated while treating of the digestive movements, and which, modified to answer this system, is as follows:—The contractions of the uterus are due to the sympathetic nerves alone; but the regularity of the contractions (namely, commencing at the Fallopian tubes and terminating at the os uteri, characteristic of true labour-pains) is due to the regulating action of the cerebro-spinal fibres.

Indeed, viewing the subject in this light, we have a ready explanation of the nature of "false pains;" namely, that they are the result of the action of the sympathetic system alone, without the consent, so to speak, of the cerebro-spinal system; an explanation strengthened by the fact that these irregular contractions occur generally in those women in whom the cerebro-spinal system is in a state of derangement.

The influence of the sympathetic system on the movements of the bladder, ureters, and vesiculæ seminales, are so similar to its action on the intestines as only to require mention.

In conclusion, we may recapitulate the results at which we have arrived. These are—1. That the sympathetic system proper is an independent system of nerves. 2. That they do not possess sensory properties, but derive sensibility from the communicating branches of the cerebro-spinal nerves. 3. That the sympathetic centres are capable of originating motion, independent of the brain and spinal cord. 4. That the so-called "inhibitory action" resides in the cerebro-spinal fibres, but, instead of an inhibition, should be regarded as a power of converting the irregular movements, originated by the sympathetic system, into a precise and definite vermicular or peristaltic action; in short, "a regulative action." And finally, that as to its relation with secreting structures, the sympathetic system exercises a peculiar power in connection with the cerebro-spinal nerves over the chemical composition of the secretion, chiefly through its influence on the condition of the blood-vessels.

Dundee Royal Asylum, August 27, 1860.

THE SPIRIT OF THE PERIODICALS.

Mr HILTON'S Lectures are continued in the 'Lancet,' and are followed by a continuation of Dr P. FRASER'S articles on *Stimulation versus Depletion*. The Author gives some important statistics to show the effect of the two methods of treatment:

"In the following summary of the tables, we give, for the convenience of comparison, three decennial periods.

"In the year 1835, there were treated as in-patients in the London Hospital, 2,735 persons, of whom 277 died, being at the rate of 10 per cent. During that year there was expended for these 2,735 patients, the sum of 615*l.* for beer; 346*l.* for wine; making a total of 961*l.* To counterbalance the effect of these stimulants, blood was drawn by 33,950 leeches, to say nothing of bleeding and cupping, then largely practised.

"In the year 1845, there were treated as in-patients 3,625 persons, of whom 228 died, being at the rate of 6¼ per cent. These patients consumed, in the course of their treatment, wine and spirits to the amount of 848*l.*; or, to be more minute, they drank 10 gallons of brandy, 236 gallons of wine, 10 gallons of gin, and 96 gallons of spirits of wine besides were exhausted. To meet this alcoholic accumulation, blood was drawn by 33,800 leeches, to say nothing of venesections, cuppings, &c.

"But what transpired in 1855? In that year 3,947 patients were treated in the hospital, of which number 294 died, being at the rate of 7¼ per cent. This number of patients consumed during the year, 143 gallons of brandy, 1,153 gallons of wine, 60 gallons of gin, and 144 gallons of spirits of wine were exhausted, at a cost of 1,796*l.* as against 848*l.* and 961*l.* for the two previous decennial periods. But now appears the strange fact, that during the year 1855, the effects of this accumulation of alcohol were diminished by the quantity of blood drawn by 4,400 leeches only, with, perhaps, not a single venesection, and at an average of not more than two cuppings per week, as against 33,800 and 33,950 leeches, frequent venesections and cuppings, for the two previous decennial periods.

"Pursuing this inquiry, it is found that in the year 1837 there were used in the London Hospital only 29 oz. of quinine, and 101 lbs. of bark. Whereas in the year 1857 the consumption of these and analogous drugs was as follows: 54 oz. of quinine, 478 lbs. of bark, 600 oz. of the disulphate of bark, and 47 oz. of the quinine with the citrate of iron. The number of patients in 1837 being 2,961; in 1857, 3,935: and the per-centage of deaths being respectively—for 1837, 14 per cent.; for 1857, 8 per cent.

"The two years above noted are sufficiently proximate to allow the same line of argument as for 1835 and 1855.

"Attention should be drawn to the fact that in the year 1844 there was expended for stimulants only 321*l.*, being the *smallest* amount during a period of 22 years; and that the mortality in that year was 6 per cent., the *smallest* per-centage of mortality during the said period of 22 years. We are not quite satisfied but that, if a rigid inquiry were made, the largest mortality would be found where the largest quantity of stimulants was given. It is to be observed that in the year 1851, when the number of patients—viz., 4,051—was larger than in 1857—viz., 3,935,—the mortality was nevertheless greater during the latter year, as 8 per cent. to 6·50 per cent.; although the increase of expenditure for articles of luxury, &c., during 1857, exceeded that of 1851 by the large sum of 962*l.*

"Another puzzle is presented on looking upon the results of the year 1858. We have in this year a less consumption of wine and spirits (namely, 573*l.* 3s. 3d.) than during the preceding 23 years, the average for the 24 years being 1,055*l.*; but the quantity of tonics remains nearly the same as in 1855:—Ammonia sesqui., 140 lbs.; quinine, 50 oz.; quinine and citrate of iron, 5 lbs.; bark, 511 lbs.; disulphate of bark, 660 oz.; leeches, 3,900.

The table from which the following additional summary is compiled brings into view rather startling and puzzling facts. It extends over a period of ten years, and therefore is a perfect average, and we have divided it, for our present purpose, into two quinquennial periods. It shows a direct rising increase annually in the expenditure of wine in the treatment of their patients by the physicians and surgeons of the hospital; and it so happens that from changes in the Staff this decennial period embraces the practice of six physicians, rendering the alterations in, at all events, the medical practice less likely to have arisen from any peculiar or personal views.

"To economise space, we have not given the quantities employed by each individual physician or surgeon, but the aggregate.

"From the year 1849 to 1853 inclusive, the annual average quantity of wine employed by each physician was 4,928 ounces. During the same period the annual average number of patients under the treatment of each physician was 390; the annual average mortality being 9·68 per cent.

"From the year 1854 to 1858 inclusive, the annual average quantity of wine employed by each physician was 12,803 ounces. During the same period, the annual average number of patients under the treatment of each physician was 391; the annual average mortality being 11·87 per cent.

"In the surgical wards a similar unexpected result is observed.

"From the year 1849 to 1853 inclusive, the annual average quantity of wine employed by each of the surgeons was 17,533 ounces. During the same period, the annual average number of patients under the treatment of each surgeon was 1,075; the annual average mortality being 4·48 per cent.

"From the year 1854 to 1858 inclusive, the annual average quantity of wine employed by

each of the three surgeons was 38,016 ounces. During the same period, the annual average number of patients under the treatment of each surgeon was 1,036; the annual average mortality being 5·06 per cent.

"It may be supposed that, as regards the medical cases, this unexpected result proceeded from a difference in the kind and severity of diseases which were fatal during the periods included in the calculations. Information on this point in these cases is not available; but as regards the surgical cases the record is complete and correct, and from it we learn that this cause does not operate, as the remarkablo fact is demonstrated by another table that the annual average number of each kind of accident during a period of ten years is very nearly alike; thus adding one more illustration of the unexpected fact elicited by statistics—namely, that the mechanical causes producing accidents in a fixed population are pretty permanent; for we cannot assume that there has been an unusual severity in the character of the accidents. The table gives a more extended basis, as regards surgical cases, to this inquiry, as it includes the out-patients as well as the in-patients; and we see at once that the same regularity continues in the kind of accidents with the larger number of patients. We repeat that we should be very sorry even to attempt to generalise on the limited data now presented to the reader; nevertheless we do consider that the facts brought out in these tables are of sufficient weight and importance to warrant us in asserting that the Profession ought to pause in an indiscriminate employment of stimulants and tonics, especially the former, in the treatment of disease even of apparently an asthenic character. Many excellent men—Mr Higginbottom, for example—have denounced the stimulant treatment *in toto*. We are not yet prepared to go so far; for where there is so much doubt, it behoves all of us to entertain tolerant views."

Mr Weeden Cooke contributes to the same journal some observations on *Rare Surgical Accidents*. We quote the case reported of suppuration of the knee-joint subsequent to fracture of the patella:

"A transverse fracture of the patella is so seldom followed by any evil result, or the records of such cases are so scanty, that I have been unablo to find more than two or three at all resembling the very remarkable case I propose briefly to report. Sir Astley Cooper mentions the case of a woman who had ulcers on various parts of the body, and one of these formed on the integuments immediately over the ligament which united a previously fractured patella. The ulcer became sloughy, and extended through the ligament into the joint; violent constitutional irritation ensued, suppuration was set up, and no opportunity was given of amputating the limb, owing to the swollen and inflamed state of the thigh: as a consequence, the woman died. Sir Charles Bell also relates the sad sequel of a case of simple fracture of this bone. He says: 'I have seen a very terrible accident follow the imperfect cure of a fractured patella. The bone had united by ligament, and this ligament had incorporated with the skin in such a manner that it lost much of its pliancy. The poor man was carrying a burden, and fell backward. The knee sank under him, and the whole fore part of the joint was laid open by laceration. The case terminated in amputation of the limb.' Mr Fergusson and others have put on record cases showing the result of compound fracture of this bone, but it is of the sequelæ of simple fracture alone that I would speak in this short paper.

"As a rule, we find that the ligament uniting the fractured portions of a patella goes on for two or three years diminishing in length and obtaining a firmer consistence, so that in many instances the patients declare that there is scarcely any loss of power in the limb, and that they can walk, and even jump, almost as well as before the injury. No doubt the constitutional powers of the patient have much to do with this consolidation of the uniting medium, as was shown in the case of a weakly man who came under my care about a twelvemonth ago. It was a case of transverse fracture, and did very well, the distance between the fractured portions not being more than an inch when he was discharged from the hospital. Two months after, he met with another fall, and was readmitted with the uniting ligament quite torn away from the inferior portion of the bone. A figure of 8 starch bandage was reapplied, and union was again very soon obtained, since which I have seen nothing of him. In the case I am about to relate, the man was also a spare, badly-nourished person, accustomed to very hard labour.

"T. S——, aged thirty-five, a carman, was admitted to the Royal Free Hospital on September 24th, 1859, under my care. Eighteen months previously he had fractured the patella transversely, and was then in the hospital under my care. The treatment was cold affusion, the V-bed, and, after five days, the starch bandage, by which means he was enabled to go out of the hospital in three weeks. The starch bandage was continued for three weeks longer, and then the union was so complete that the upper portion of the bone could scarcely be moved upon the lower. He has since that continued his work without any inconvenience, until September 2nd, when, without any assignable cause, he was seized with great pain in the knee during the night; much inflammation subsequently set in, and he remained at his own home under treatment until the date of his admission. It was then found that suppuration had ensued, and the uniting ligament was absorbed. The two portions of the patella were separated some four inches; there were three small openings above and around the knee, communicating with the interior of the joint, and discharging freely unhealthy purulent matter. The pulse was small and rapid; tongue dry and very red. He had cold perspirations, and suffered great pain. Fortunately the poor fellow was able to take his food tolerably well, and I therefore allowed him full diet, with port wine and stout, the medication being tincture of bark and hydrochloric acid, with linseed poultices to the knee. In a few days the inflammation subsided at the knee, and the purulent discharge became less; but on October 3rd an abscess pointed at the inner side of the calf, from which by incision I drew off two ounces of laudable pus. From the same opening on the 5th nearly half a pint of pus was obtained by passing a probe to clear the passage. On the 8th another large quantity of pus came away in the same manner, mixed with clots of black blood. Tents were now kept in this wound and in the openings below the knee, and much sanguineo-purulent matter continued to be discharged.

"For three weeks there was scarcely any change in the condition of the limb, but the powers of life did not fail, and all the time he took his food and stimulants freely. At the beginning of November, the discharge began to diminish and the wounds to heal. In the middle of this month he had an attack of subacute inflammation of the wrist and shoulder joints, but his general health was not much affected by it. On the 3rd of December, these joints were well again, the wounds were nearly healed, and the discharge trifling.

"Dec. 12th.—Wounds all healed; no pain in the leg, which is of course quite stiff; and he is getting about with crutches. The left hand and wrist are now swollen and painful.

"19th.—Able to stand on the injured leg; some swelling of the right wrist.

"28th.—Discharged quite well; no pain of joints; able to get about with one cruteh.

"Chlorate of potash was added to the bark and acid when the joint affections came on, and it seemed to act very beneficially. The healing of the wounds was also much hastened, when the active disease had subsided, by encasing the knee and leg in strips of lint spread with soap cerate. No bone came away during the progress of the case, and the upper portion of the patella remained separated from the lower portion by a space of between three and four inches.

"The obvious moral to be derived from this case is, never to despair of the curative powers of Nature, so long as the wear and tear can be supplied by sufficient nourishment. Here was a case of suppurative inflammation of the most important joint in the body, followed by pyæmia, in which life and limb were both saved by a little surgical management, and a good deal of constitutional support; perfect rest to the limb, and immediate evacuation of pus whenever and wherever it presented itself being all the surgical interference that was called for; whilst the few medicines employed may fairly be looked upon as dietetics, or, at any rate, as condiments provocative of appetite for the food which was to effect the cure. In days now happily passing away,—let us hope for ever,—the alarm created by the formation of pus in the knee-joint after an injury would have induced the surgeon to advise amputation of the limb in order to save the life of the patient. Even in this case had the *cacoethes detruncandi* been strong upon me, there was a time when that resource seemed to be justified; but having a firm trust in the healing powers of Nature, and a patient with a cheerful disposition, we were fortunately enabled to weather the storm without throwing overboard any part of our valuable cargo."

Mr Henry Lobb reports the following case of *Rheumatic Ophthalmia* of long standing treated with the continuous galvanic current:

"R. J—— had suffered for more than fifteen years from repeated attacks of rheumatic ophthalmia, through which the pupil of one eye had become permanently contracted, and the sight of the other much injured. Being warned that a repetition of these attacks would be followed by total loss of sight, he was led to consider whether some means of prevention hitherto untried might not exist. He had found by experience that galvanism applied to th limbs removed rheumatic pains; he therefore thought that a modified current applied to the eye at the commencement of an attack might prevent its occurrence, and if applied for a sufficient length of time the cure might be permanent.

"On the approach of the next attack, he accordingly applied an excited thirty-six link Pulvermacher chain, the positive pole upon the spine, the negative upon the closed eyelid, upon retiring to rest. This was allowed to remain on during the night. In the morning, every trace of the disorder had vanished.

"Other attacks followed at gradually-increasing intervals of time, but they were invariably arrested by the same means, the consequence being, that during the last five years R. J—— has found that his eyes have been gaining strength, enjoying the uninterrupted use of his sight during the whole time.

"The above case, communicated by the patient himself, requires no comment from me, as it is related in so plain and straightforward a manner. At the same time, I may corroborate it by stating, that in all cases of ophthalmia for which I have used the continuous galvanic current a rapid cure has been effected."

The 'Medical Times and Gazette' opens with a continuation of Dr J. Y. Simpson's Lectures on the Diseases of Women. The present lecture treats of *Puerperal Mania*. We extract it:

"Gentlemen,—We had, a short time ago, in the hospital, a recent case of vesico-vaginal fistula. The patient died, but not in consequence of any operation attempted for the relief of that disorder, but of an acute attack of puerperal mania. In taking advantage of this unfortunate case to make some observations on the nature, the causes, and the treatment of this disease, let me first of all briefly acquaint you with the patient's sad history.

"Case.—Christina S., admitted into the hospital on March 20, 1860, was a factory girl of twenty-five years of age, and of feeble mental constitution. Eight weeks before admission she was confined, in the country, for the first time, of an illegitimate child; and was in labour for three days. The pains, according to her own account, were so severe that she was constrained to keep her bed throughout the entire period. The child was still-born; although she stated that she was sensible of its movements not long before its delivery. There was no Medical man in attendance, and no instrumental or other artificial aid was afforded her, the whole process having been conducted by a midwife. From the date of her confinement she made no water through the urethra, but it kept escaping through the vagina. On examination per vaginam, a large fistula was found opening into the bladder, of an oval form, and reaching from below the os uteri more than half-way down the anterior vaginal wall. When she entered the hospital, the edges of the fistulous aperture were already thickened and indurated, and there was a strong cicatricial band

stretching across the back wall of the vagina, and greatly narrowing its diameter. The patient was slovenly and dirty in her habits—as is frequently the case with partially idiotic individuals,—and in consequence the pudenda and inner surfaces of the thighs and hips were in a very filthy, irritable, and inflamed condition. For the first day or two after her admission Carron oil and zinc ointment were applied externally, while bismuth pessaries were introduced into the vagina. On the 24th, the excoriation having been greatly relieved, and the patient's general health somewhat improved, the band across the back wall of the vagina was divided by a slight incision, in order to gain sufficient subsequent space for the operation of the closure of the large fistula. The simple division of the vaginal constricting band was attended with almost no hæmorrhage and but little pain; and for two days the patient seemed to be quite well, although she still showed herself, as she had from the first been, singularly stubborn, and very averse to talk or answer any questions that were addressed to her. On the morning of the 27th the other patients in the ward complained of her being very noisy and troublesome during the preceding night, and of having been deprived of their rest in consequence. But there was no great indication yet of any mental or bodily excitement: the pulse was quiet and rather weak. On the following night, however, she became so noisy and violent that she had to be removed to the ward appropriated to the insane, where she lay for three days with the mental faculties completely in abeyance, being sometimes slightly excited, but usually quiet and unimpressible, speaking incoherently when addressed, and immediately relapsing into stupor. The pulse was weak, irregular, and rapid; and on April 1 she sank and died. On making a post-mortem examination, the large vesico-vaginal fistula was found stretching from the lower half of the vagina close up to the os uteri. The slight wound in the band crossing the posterior wall was granulating and healthy, and presented no trace of over-action. The kidneys were slightly fatty; the other abdominal and pelvic organs normal. No lesion could be discovered in the brain itself; but the meninges were thickened and vascular, and the skull was deformed and very irregular in shape.

"The disease, which you have had an opportunity of seeing and following to its rapid termination in this unfortunate patient, is by no means very frequent among puerperal patients. Yet the statistics of insanity appear to show that about ten per cent. of all the females found in lunatic asylums have become the inmates of these institutions in consequence of puerperal mania. Insanity may supervene at various periods in connection with the process of reproduction. (1.) It occasionally occurs during the progress of pregnancy. In such cases it has been observed, that although the disease may be prolonged to the puerperal period, and even on to a more distant date, yet that most frequently it disappears on the termination of labour. Let me remark, in contrast with this fact, that some curious cases have been recorded where women, previously of unsound mind, have become sane, and remained so, during the whole term of their pregnancy. (2.) Again, while labour is progressing, a patient may be the subject of an attack of mania. Usually this form of mania or delirium is brief and evanescent. It was specially described and illustrated by my late friend Dr Montgomery. This temporary variety of insanity during labour seems to be excited by the mere intensity of the pains, and is most marked, or most frequently seen, towards the close of the second stage. Usually it manifests itself in wild, incoherent, or improper utterances on the part of the patient, and passes off as the labour is brought to its termination. I have known it, in one instance, assume the form of impulsive suicide; the patient, in the case I advert to, having sprung out of bed and seized a razor in the agony of her sufferings when the os uteri was on the full stretch at the end of the first stage of labour. After the head passed down into the vagina this state of delirium vanished, and the patient was then as horrified as her attendants had previously been at the maddening impulse which had previously seized her. But puerperal mania—properly so called—rarely occurs till after delivery. Its most general date of appearance is (3) during the first two months after delivery, but especially during the first two weeks of that period; and (4) in some patients it only comes on during lactation, and occasionally, indeed, it does not appear till the end of that process. It is of puerperal mania—as seen after delivery—that I intend to speak to you at present. The special date at which it may come on after parturition can be seen from this table constructed by Esquirol:—

"*Date of the Attack of Puerperal Mania in Ninety-two Cases.*—16 were attacked from the 1st to the 4th day after delivery; 21 from the 5th to the 15th day; 17 from the 16th to the 60th day; 19 from the 60th to the 12th month of lactation. 19 were attacked after forced or voluntary weaning.

"Ætiology and Pathology of the Disease.

"The causes and pathological nature of puerperal mania have not yet been clearly elucidated; and of the various theories that have been advanced regarding this always distressing malady, there is none that can be held as applicable to more than a certain group of cases. It is, however, a subject of great interest, and one in regard to which renewed investigations and original observation may yet yield important results. One well-established fact in connection with it is, that in a large number of persons puerperal mania is found associated with a

"1. *Hereditary Predisposition to Insanity.*—I know, for instance, of one case where a lady was attacked five times with puerperal mania after as many successive confinements, and in whom the proclivity to these diseases seemed dependent on some hereditary and constitutional condition, for several of the other members of the family to which she belonged were at different times under treatment for some form of mental disorder. In none of her first confinements had the lady I speak of used chloroform; but on the occasion of her sixth delivery she insisted on being anæsthetised, and for the first time after so many labours she recovered without once manifesting any tendency to insanity. Dr Montgomery has related the history of a case where a lady belonging to a family hereditarily predisposed to insanity became the mother of eight children; and on the occasion of the birth of each of her infants she passed through an attack of puerperal mania. Cases such as these come under observation from time to time; and although assuredly it does not often happen that a person who is hereditarily predisposed to mental disorders becomes the subject of puerperal mania when she gives birth to a child, yet when a person so predisposed has once had an attack of the disease, her future labours must ever be looked forward to with much anxiety by her Medical attendant, and her progress marked with the greatest care. It is calculated that in about forty or fifty per cent. of all cases of puerperal mania, some hereditary predisposition to insanity can be traced. In nearly one-half, therefore, of all the instances of the disease which may appear in practice, you will fail in establishing any such hereditary tendency. But, whether traceable or not in the history of the patient or her relatives, mere hereditary predisposition affords in itself no adequate explanation of the actual occurrence of an attack of puerperal, or indeed of any other form of insanity. Can we trace in the puerperal female any special exciting causes or conditions capable of exciting this special disease? Pathologists and obstetricians have attempted to refer the excitement of puerperal mania to different morbid states more or less frequently found in connection with delivery and lactation; as,
